- Nephritis: Progressive degeneration of nephrons focal glomerulosclerosis

Type IV renal tubular acidosis, hyperkalemic nephropathy, interstitial nephritis, causing hyporeninemic hypoaldosteronism. It is important to keep in mind that NSAIDs, ACE inhibitors, trimethoprim, and heparin can all reduce aldosterone and can cause or exacerbate the condition. 50% of patients on dialysis have diabetes as primary diagnosis; whereas glycemia is important to prevent nephropathy, the most significant contributing factor is hypertension.

- Foot ulcers: Occur in 15% of individuals with diabetes (annual incidence rate 2%) and are the leading causes of hospitalization; they are usually secondary to a combination of factors, including peripheral vascular insufficiency, repeated trauma (unrecognized because of sensory loss), and superimposed infection.
  1. Patient symptoms are usually less than would be expected from clinical findings, due to loss of sensation related to peripheral neuropathy.
  2. Comprehensive foot exams include visual inspection, assessment of pedal pulses, and assessment of protective sensation using a 10-g monofilament to test sensation.
  3. Prevention of foot ulcers in an individual with diabetes includes strict glucose control, patient education, prescription footwear, intensive podiatric care, and evaluation for surgical interventions.
  4. Foot examination should be done annually on all diabetics.
- Neuropathic arthropathy (Charcot joints): Bone or joint deformities from repeated trauma (secondary to peripheral neuropathy; Fig. E1).
- Necrobiosis lipoidica diabeticorum: Plaque-like reddened areas with a central area that fades to white-yellow, found on the anterior surfaces of the legs (Fig. E2); in these areas, the skin becomes very thin and can ulcerate easily.
- Other diabetic skin manifestations with diabetes include:
  1. Scleredema diabeticorum: Thickening of skin and epidermis giving skin a "leather-like texture"; typically affects type 2, mainly on upper back and neck.
  2. Dermatitis herpetiformis: Diffuse petechial rash associated with gluten insensitivity.
  3. Vitiligo: Associated with type 1 and type 2, and affects skin coloration due to autoimmune reaction to pigmentation (at times may be associated with adrenal insufficiency, especially in type 1 patients). Patients should use SPF 30 sunscreen to prevent sunburn.
  4. Acanthosis nigricans: Darkening of skin folds in neck and axilla, at times raised and velvety, thought to be associated with insulin resistance; other conditions such as Cushing and acromegaly can have this as well.
  5. Diabetic dermopathy: Appears as shiny round or oval lesions on thin skin of the lower extremity, also known as "shin

spots"; these are usually not painful and do not require treatment.
6. Eruptive xanthomatosis: Associated with uncontrolled blood sugars and extremely high triglycerides. There is a high risk for pancreatitis in patients with this finding; treatment is aimed at lowering blood sugars with insulin and fibrates.
7. Digital sclerosis: Skin on toes fingers and hands become waxy, thick, and tight, with joint stiffness; treatment is aimed at lowering blood sugars and encouraging use of lotions and moisturizers.
8. Bullosis diabeticorum: Rare disorder manifesting with blisters on hands, forearms, toes, and feet, usually painless. Lesions generally heal on their own.
9. Box 1 summarizes cutaneous associations with diabetes mellitus.

ETIOLOGY

IDIOPATHIC DIABETES: Type 1 DM: Results from autoimmune beta-cell destruction, usually leading to absolute insulin deficiency.
- Hereditary factors:
  1. Islet cell antibodies (found in 90% of patients within the first yr of diagnosis)
  2. Higher incidence of human leukocyte antigen (HLA) types DR3, DR4
  3. 50% concordance rate in identical twins
- Environmental factors: Viral infection (possibly coxsackievirus, mumps virus)

Type 2 DM: Results from insulin resistance and a progressive defect in insulin secretion.
- Hereditary factors: 90% concordance rate in identical twins
- Environmental factors: Obesity, sedentary lifestyle, high carbohydrate content in food

DIABETES SECONDARY TO OTHER FACTORS:
- Hormonal excess: Cushing syndrome, acromegaly, glucagonoma, pheochromocytoma
- Drugs: Glucocorticoids, diuretics, oral contraceptives
- Insulin receptor unavailability (with or without circulating antibodies)
- Pancreatic disease: Pancreatitis, pancreatectomy, hemochromatosis, cystic fibrosis
- Genetic syndromes: Maturity onset diabetes of the young (MODY, monogenetic diabetes accounting for 2% to 5% of diabetes), familial hyperlipidemias, myotonic dystrophy, lipoatrophy
- Gestational diabetes (GDM): Diabetes diagnosed during pregnancy that is due to pregnancy-related insulin resistance

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diabetes insipidus
- Stress hyperglycemia
- Diabetes secondary to hormonal excess, drugs, pancreatic disease

LABORATORY TESTS

- Diagnosis of DM is made on the basis of the following tests:
  1. Fasting glucose ≥126 mg/dl on two occasions.
  2. Non-FPG ≥200 mg/dl and symptoms of DM.
  3. OGTT (75 g glucose load for nonpregnant individuals) with 2-hr value >200 mg/dl.
  4. Glycosylated hemoglobin (HbA_{1c}) ≥6.5%. HbA_{1c} level reflects average glycemia over previous 3 mo or longer. In known diabetics, this test should be performed at least twice yearly in stable patients and more frequently when therapy changes or patients are not meeting glycemic goals. HbA_{1c} alone does not provide a measure of glycemic variability or hypoglycemia and is affected by the presence of hemoglobin variants, hemolysis, or blood loss.
- Measurement of autoantibodies glutamic acid decarboxylase (GAD65) and tyrosine phosphatase IA-2 are useful in suspected immune mediated type 1 DM (strong association).
- Screening for prediabetes and diabetes in asymptomatic patients (see Table 3):
  1. Should be considered in adults of any age who are overweight (body mass index [BMI] >25 kg/m^2) or obese (BMI >30) and who have one or more additional risk factors for diabetes.
  2. In those who are without these risk factors, testing should begin at age 45 yr.

BOX 1 Some Cutaneous Associations with Diabetes Mellitus

Established or Probable Association
- Necrobiosis lipoidica (NL) diabeticorum
- Diabetic dermopathy
- Diabetic bullae
- Acanthosis nigricans
- Acrochordons (skin tags)
- Scleredema diabeticorum
- Limited joint mobility and waxy skin syndrome
- Partial lipodystrophy
- Malignant otitis externa
- Neuropathic leg ulcers
- Perforating disorders
- Eruptive xanthomas
- Hemochromatosis
- Carotenemia
- Pruritus
- Xerosis and anhidrosis
- Yellow nails, koilonychia
- Increased susceptibility to infections:
  - *Candida albicans*
  - *Staphylococcus aureus*
  - Group A β-hemolytic streptococcus
  - *Pseudomonas aeruginosa*
  - Dermatophytes (tinea pedis, onychomycosis)
  - *Corynebacterium minutissimum* (erythrasma)

Possible Association
- Disseminated granuloma annulare
- Vitiligo

From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.

TABLE 3 Criteria for Diabetes Screening in Asymptomatic Individuals

1. Testing should be considered in all adults who are overweight (BMI >25 kg/m^2*) and have additional risk factors:
   1. Physical inactivity
   2. A first-degree relative with diabetes
   3. High-risk ethnic population (e.g., African American, Hispanic American, Native American, Asian American, Pacific Islander)
   4. Delivered a baby weighing more than 9 lb or diagnosed with gestational diabetes mellitus
   5. Systemic hypertension (blood pressure >140/90 mm Hg or on antihypertensive therapy)
   6. High-density lipoprotein cholesterol level <35 mg/dl or triglyceride level >250 mg/dl
   7. Polycystic ovary syndrome
   8. Hemoglobin A_{1c} ≥5.7%, impaired glucose tolerance or impaired fasting glucose on prior testing
   9. Other clinical conditions associated with insulin resistance (e.g., severe obesity, acanthosis nigricans)
   10. History of cardiovascular disease
2. If none of the above criteria are present, screening for diabetes should begin at age 45 yr.
3. If the results are normal, screening should be repeated at least every 3 yr. Depending on initial results and risk status, more frequent testing may need to be considered.

*In some ethnic groups, such as Asians, at-risk body mass index (BMI) may be lower.

Modified from American Diabetes Association: Diagnosis and classification of diabetes mellitus, *Diabetes Care* 33(Suppl 1):S14, 2010; and from Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

3. If screen is normal, repeat testing should be carried out at least at 3-yr intervals.
4. ADA recommends screening all Asian Americans with BMI 23 or higher every 2 yr.

- Detection and diagnosis of gestational diabetes mellitus (GDM):
  1. Screen for GDM using risk factor analysis and use of an OGTT. Pregnant women who are not known to have diabetes should be screened for gestational diabetes at 24 to 28 wks' gestation with a "1-step" strategy with 75 g oral glucose tolerance test or a "2-step" approach with a 50-g (nonfasting) screen followed by a 100-g oral glucose tolerance test for those who screen positive. A diagnosis of GDM is made if any of the following levels of plasma glucose are exceeded: ≥92 mg/dl (5.1 mmol/L) when fasting, ≥80 mg/dl (10 mmol/L) at 1 hour, or ≥153 mg/dl (8.5 mmol/L) at 2 h.
  2. Women with GDM should be screened for diabetes 6 to 12 wk postpartum and should be followed with subsequent screening for the development of diabetes or prediabetes at least every 3 yr. A woman who had GDM during pregnancy has 50% risk of developing diabetes later in life; this is dependent on ethnicity (e.g., Pima Indians, Hispanic, African American).
- Screening for diabetic nephropathy:
  1. Screening should be done at diagnosis and then yearly for type 2 diabetes and 5 yr after diagnosis then yearly in type 1 diabetes. 18% of type 1 DM may have early kidney changes, and future guidelines may change screening to 1 yr after diagnosis if poorly controlled then annually for both type 1 and type 2.
  2. Screening can be performed using an albumin:creatinine ratio (microalbumin) in a random spot urine collection or by measurement of a 24-hr urine collection for albumin and creatinine clearance. The urine albumin to creatinine ratio (ACR) is independently associated with mortality at all levels of estimated glomerular filtration rate (eGFR) in older adults with diabetes.
  3. The diagnosis of microalbuminuria (ACR 30-299 mg/24 hr) should be based on 2 to 3 elevated levels within a 3- to 6-mo period because there is a marked variability in day-to-day albumin excretion. Patients with overt macroalbuminuria (>300 mg albumin/24 hr or albumin:creatinine ratio >300) should be followed by urine protein:creatinine ratio.
- A fasting serum lipid panel, serum creatinine, and electrolytes should be obtained yearly on all adult patients with diabetes.
- Self-monitoring of blood glucose (SMBG) is crucial for assessing the effectiveness of the management plan. The frequency and timing of SMBG varies with the needs and goals of each patient. In most patients with type 1 DM and pregnant women taking insulin, SMBG is recommended at least 3 times/day. In patients with type 2 DM not on insulin, recommendations are unclear for SMBG, but testing once or twice/day is acceptable in most patients. Glycemic control is best evaluated when SMBG is combined with HbA_{1c} testing.
- Continuous glucose monitoring (CGM) is now starting to play a more prominent role in reducing the number of fingersticks. Dexcom CGM has been approved by FDA for use by patients to adjust insulin based on CGM readings.
- The use of insulin pump and CGM readings and computer software can adjust insulin automatically (known as the "artificial pancreas").
- CGM can also be used in patients with type 2 on multiple daily injections.
- Limitations of CGM are that it cannot predict accuracy of blood glucose when <70 mg/dl.
- Screening for thyroid dysfunction (TSH level), vitamin B_{12} deficiency, and celiac disease should be considered in type 1 diabetes due to the increased frequency of other autoimmune diseases in these individuals.
- Consider screening for autoimmune polyendocrine syndromes (APS-2):
  1. APS-2: Most commonly known as Schmidt syndrome, heterogeneous not linked to one gene (HDLA-DQ2, HDLA-DQ8, AND HLA-DR4). Patients can have IDDM, hyperthyroidism, other autoimmune conditions, B_{12} deficiency, and myasthenia.

Rx TREATMENT

- Type 1 diabetes requires immediate initiation of insulin therapy.
- In type 1 diabetes, intensive glycemic control (HbA_{1c} <7) has been shown in randomized controlled trials (RCT) to reduce the risk of microvascular (neuropathy, retinopathy, nephropathy) and macrovascular (cardiovascular events) complications.
- Type 2 DM: The ADA and European Association for the Study of Diabetes recommend lifestyle intervention (diet and exercise) and metformin initiation (unless contraindications exist such as serum creatinine levels ≥1.5 mg/dl in males or ≥1.4 mg/dl in females or patients ≥30 yr of age with reduced renal function as measured by creatinine clearance) at the time of diagnosis of type 2 diabetes. Therapy should then be augmented with additional agents (including early initiation of insulin therapy) to achieve adequate glycemic control.
- In type 2 diabetes, intensive glycemic control (HbA_{1c} <7) has been shown in RCT to reduce the risk of microvascular complications. While intensive glucose control reduced the risk of some CVD outcomes (such as nonfatal MI), it did not reduce the risk of cardiovascular death or all-cause mortality and increased the risk of severe hypoglycemia.
- Table 4 summarizes American College of Cardiology/American Heart Association (ACC/AHA) recommendations for primary prevention of CVD in patients with diabetes. Recommendations for secondary prevention of CVD are described in Table 5.
- It is important to remember that tight glycemic control may burden patients with complex treatment programs, hypoglycemia, weight gain, and costs. Clinicians should individualize HbA_{1c} targets so that they are reasonable and reflect patients' personal and clinical contexts and their informed values and preferences. A target HbA_{1c} <7 is reasonable for motivated new diabetic patients with long life expectancies, whereas less stringent controls (HbA_{1c} 7.5 or higher) may be reasonable in elderly patients with limited life expectancy and elevated risk of hypoglycemia. The American Geriatrics Society recommends a general goal for glycated hemoglobin in older adults of 7.5% to 8.0%. Higher HbA_{1c} targets (8% to 9%) are appropriate for older adults with multiple comorbidities, poor health, and limited life expectancy.[1]

NONPHARMACOLOGIC THERAPY

- Diet: The ADA does not recommend a special diet. However, newly diagnosed diabetics who are overweight or obese should be counseled to lose at least 5% of their body weight. Medical association therapy with a registered dietitian is recommended.
  1. Calories:
     a. The patient with diabetes can be started on 15 calories/lb of ideal body weight; this number can be increased to 20 calories/lb for an active person and 25 calories/lb if the patient does heavy physical labor.
     b. The calories should be distributed as 45% to 65% carbohydrates, <30% fat, with saturated fat limited to <7% of total calories, and 10% to 30% protein. Daily cholesterol intake should not exceed 300 mg.
     c. The emphasis should be on complex carbohydrates rather than simple and refined starches, and on polyunsaturated instead of saturated fats in a ratio of 2:1.
     d. The glycemic index compares the increase in blood sugar after the ingestion of simple sugars and complex carbohydrates with the increase that occurs after the absorption of glucose; equal amounts of starches do not give the same increase in plasma glucose (pasta equal in calories to a baked potato causes less of an increase than the potato); thus, it is helpful to know the glycemic index of a particular food product.
  2. Fiber: Insoluble fiber (bran, celery) and soluble globular fiber (pectin in fruit)

[1]Huang ES, Davis AM: Glycemic control in older adults with diabetes mellitus, *JAMA* 314:1509-1510, 2015.

TABLE 4 American College of Cardiology Foundation/American Heart Association Recommendations for Primary Prevention of Cardiovascular Disease in People with Diabetes

Lifestyle Management

Weight

Structured programs that emphasize lifestyle changes such as reduced fat (<30%-35% of daily energy) and total energy intake and increased regular physical activity, along with regular participant contact, can produce long-term weight loss on the order of 5% to 7% of starting weight, with improvement in BP.

For persons with elevated plasma triglycerides and reduced HDL-C, improved glycemic control, moderate weight loss (5%-7% of starting weight), dietary saturated fat restriction, increased physical activity, and modest replacement of dietary carbohydrate (5%-7%) by either monounsaturated or polyunsaturated fats may be beneficial.

Medical Nutrition Therapy

To achieve reductions in LDL-C:

Saturated fats should be less than 7% of energy intake.

Dietary cholesterol intake should be less than 200 mg/day. Intake of *trans* unsaturated fatty acids should be less than 1% of energy intake.

Total energy intake should be adjusted to achieve body weight goals.

Total dietary fat intake should be moderated (<30%-35% of total calories) and should consist mainly of monounsaturated or polyunsaturated fat.

Ample intake of dietary fiber (≥14 g/1000 calories consumed) may be of benefit.

If individuals choose to drink alcohol, daily intake should be limited to one drink for adult women and two drinks for adult men. One drink is defined as 12 ounces (oz) of beer, 4 oz of wine, or 1.5 oz of distilled spirits. Alcohol ingestion increases caloric intake and should be minimized when weight loss is the goal.

Individuals with elevated plasma triglyceride levels should limit intake of alcohol because it may exacerbate hypertriglyceridemia.

In both normotensive and hypertensive persons, a reduction in sodium intake may lower BP. The goal should be to reduce sodium intake to 1200-2300 mg/day (50-100 mmol/day), equivalent to 3000-6000 mg/day sodium chloride.

Physical Activity

To improve glycemic control, assist with weight loss or maintenance, and reduce risk for CVD, at least 150 min of moderate-intensity aerobic physical activity or at least 90 min of vigorous aerobic exercise per wk is recommended. The physical activity should be distributed over at least 3 days per wk, with no more than 2 consecutive days without physical activity.

For long-term maintenance of major weight loss, a larger amount of exercise (7 hours of moderate or vigorous aerobic physical activity per wk) may be helpful.

Blood Pressure

BP should be measured at every routine diabetes visit. Patients found to have SBP ≥130 mm Hg or DBP ≥80 mm Hg should have BP confirmed on a separate day.

Patients with diabetes should be treated to achieve SBP at least <140 mm Hg and DBP <90 mm Hg, and for patients who can tolerate without adverse symptoms, targets can be as low as SBP <130 mm Hg and DBP <80-85 mm Hg. Patients with SBP of 130-139 mm Hg or DBP of 80-89 mm Hg should initiate lifestyle modification alone (weight control, increased physical activity, alcohol moderation, sodium reduction, and emphasis on increased consumption of fresh fruits, vegetables, and low-fat dairy products) for a maximum of 3 mo. If, after these efforts, targets are not achieved, treatment with pharmacologic agents should be initiated.

Patients with hypertension (SBP ≥140 mm Hg or DBP ≥90 mm Hg) should receive drug therapy in addition to lifestyle and behavioral therapy.

All patients with diabetes and hypertension should be treated with a regimen that includes either an ACE inhibitor, or if intolerant to an ACE inhibitor, an ARB. If one class is not tolerated, the other should be substituted. Other drug classes demonstrated to reduce CVD events in patients with diabetes—dihydropyridine calcium channel blockers, thiazide diuretics (chlorthalidone and indapamide), and beta-blockers—should be added, in listed order of preference, as needed to achieve BP targets.

If ACE inhibitors, ARBs, or diuretics are used, kidney function and serum potassium levels should be monitored within the first 3 mo. If BP is stable, follow-up could occur every 6 mo thereafter.

Multidrug therapy generally is required to achieve BP targets.

In elderly hypertensive patients, BP should be lowered gradually to avoid complications.

Orthostatic measurement of BP should be performed in people with diabetes and hypertension when clinically indicated.

Patients not achieving target BP despite multidrug therapy should be referred to a physician specializing in the care of patients with hypertension.

Lipids

In adult patients with diabetes, lipid levels should be measured at least annually and more often if needed to achieve goals. In adults with diabetes who are younger than 40 with low-risk lipid values (LDL-C <100 mg/dl, HDL-C >50 mg/dl, triglycerides <150 mg/dl), lipid assessments may be repeated every 2 yr.

Lifestyle modification deserves primary emphasis in all individuals with diabetes. Patients should focus on the reduction of saturated fat and cholesterol intake, weight loss (if indicated), and increases in dietary fiber and physical activity. These lifestyle changes have been shown to improve the lipid profile in patients with diabetes. In persons with diabetes who are older than 40 yr, without overt CVD, statin therapy should be considered for primary prevention with recommendation to use at least moderate-dose and ideally intense-dose statins, independent of baseline LDL-C levels. On maximally tolerated statin, the goal is an LDL-C level <100 mg/dl (2.6 mmol/L), and ideally <70 mg/dl (1.8 mmol/L) for those at highest CVD risk. If LDL-lowering drugs are used, a reduction of at least 50% in LDL-C levels should be obtained.

If baseline LDL-C is <100 mg/dl, statin therapy should be initiated based on risk factor assessment and clinical judgment. Major risk factors in this category include age, sex, race/ethnicity, cigarette smoking, hypertension (BP >140/90 mm Hg or use of antihypertensive medication), high total cholesterol and low HDL-C (<40 mg/dl), and family history of premature CHD (CHD in male first-degree relatives ≤55 yr of age; CHD in female first-degree relatives ≤65 yr of age).

In people with diabetes who are younger than 40, without overt CVD, but who are estimated to be at increased risk for CVD either by clinical judgment or by risk calculator, at least moderate-intensity statin therapy is recommended, with an LDL-C goal of <100 mg/dl.

Combination therapy with LDL-lowering drugs (e.g., statins, ezetimibe, PCSK9 inhibitors) and fibrates or niacin may be necessary to achieve lipid targets, but to date, only the addition of ezetimibe to statin therapy has proven incremental CV outcomes benefit.

Beyond the consensus of therapeutic lifestyle intervention, the ADA and AHA guidelines have evolved significantly over recent years, no longer recommending pharmacologic treatment of low HDL-C or high triglyceride levels, except for those with extremely high fasting triglyceride levels, to consider fish oil or a fibrate to mitigate pancreatitis risk.

Tobacco

All patients with diabetes should be asked about tobacco use status at every visit.

Every tobacco user should be advised to quit.

The tobacco user's willingness to quit should be assessed.

The patient can be assisted by counseling and by developing a plan to quit.

Follow-up, referral to special programs, or pharmacotherapy (including nicotine replacement and bupropion) should be incorporated as needed.

TABLE 4 American College of Cardiology Foundation/American Heart Association Recommendations for Primary Prevention of Cardiovascular Disease in People with Diabetes—cont'd

Antiplatelet Agents

The ADA and AHA recommend aspirin therapy (75-162 mg/day) for primary prevention in patients with diabetes at increased CV risk (e.g., estimated 10-yr risk >10%), including most age ≥50 yr who have additional risk factors (e.g., family history of CVD, hypertension, smoking, dyslipidemia, albuminuria). In contrast, the ESC/EASD guidelines discourage aspirin for primary prevention in patients with diabetes, except for those estimated to be at the very highest CV risk, in whom such use may be considered.

People with aspirin allergy, bleeding tendency, existing anticoagulant therapy, recent gastrointestinal bleeding, and clinically active hepatic disease are poor candidates for aspirin, especially for primary prevention. Other antiplatelet agents may be a reasonable alternative for patients with high risk.

Glycemic Control

The HbA_{1c} goal for most patients with diabetes in general is less than 7% in the absence of CVD, with higher targets such as 8% (or higher) endorsed for patients with moderate to severe CVD or other serious comorbidities.

Type 1 Diabetes Mellitus

At present, all of the recommendations listed above for patients with type 2 DM appear to be appropriate for those with type 1 DM as well.

ACE, Angiotensin-converting enzyme; *ADA,* American Diabetes Association; *AHA,* American Heart Association; *ARB,* angiotensin receptor blocker; *BP,* blood pressure; *CHD,* coronary heart disease; *CV,* cardiovascular; *CVD,* cardiovascular disease; *DBP,* diastolic blood pressure; *DM,* diabetes mellitus; *EASD,* European Association for the Study of Diabetes; *ESC,* European Society of Cardiology; *HbA_{1c},* glycosylated hemoglobin; *HDL-C,* high-density lipoprotein cholesterol; *LDL-C,* low-density lipoprotein cholesterol; *SBP,* systolic blood pressure.

TABLE 5 American College of Cardiology Foundation/American Heart Association Recommendations for Secondary Prevention of Cardiovascular Disease Specific to Patients with Diabetes

Class	Indication	Level of Evidence
I	Care for diabetes should be coordinated with the patient's primary care physician and/or endocrinologist.	C
	Lifestyle modifications including daily physical activity, weight management, blood pressure control, and LDL cholesterol management are recommended for all patients with diabetes.	B
	ACE inhibitors (or ARBs for those with ACE inhibitor intolerance) should be started and continued indefinitely in patients with diabetes, unless contraindicated.	A
	Use of aldosterone blockade in post-MI patients without significant kidney dysfunction or hyperkalemia is recommended in patients who are already receiving therapeutic doses of an ACE inhibitor and beta-blocker, who have a left ventricular ejection fraction ≤40% and diabetes.	A
IIa	Metformin is an effective first-line pharmacotherapy and can be useful if not contraindicated.	A
	Individualizing the intensity of blood glucose–lowering interventions based on the individual patient's risk for hypoglycemia during treatment is reasonable.	C
IIb	Initiation of pharmacotherapy interventions to achieve target HbA_{1c} may be reasonable.	A
	A target HbA_{1c} of ≤7% may be considered, whereas the ADA/EASD endorse a target ≥8% for those with moderate to severe CVD.	C
	Less stringent HbA_{1c} goals may be considered for other patients with a history of severe hypoglycemia, limited life expectancy, advanced microvascular complications, or extensive comorbidity, or those in whom the goal is difficult to attain despite intensive therapeutic interventions.	C

ACE, Angiotensin-converting enzyme; *ADA,* American Diabetes Association; *ARB,* angiotensin receptor blocker; *CVD,* cardiovascular disease; *EASD,* European Association for the Study of Diabetes; *HbA_{1c},* glycosylated hemoglobin; *LDL,* low-density lipoprotein; *MI,* myocardial infarction.

Data are from Fox CS et al: Update on prevention of cardiovascular disease in adults with type 2 diabetes mellitus in light of recent evidence: a scientific statement from the American Heart Association and the American Diabetes Association, *Circulation* 132:691-718, 2015; Ryden L et al: ESC guidelines on diabetes, pre-diabetes, and cardiovascular diseases developed in collaboration with the EASD. delay glucose absorption and attenuate the postprandial serum glucose peak.
   a. They also appear to reduce the increased triglyceride level often present in patients with uncontrolled diabetes. A diet high in fiber should be emphasized (20 to 35 g/day of soluble and insoluble fiber).
   b. Diet programs: In 2015, a meta-analysis review of all research revealed that weight loss was equal no matter which diet program patients were involved in.
   c. However, the only data to show evidence-based prevention of diabetes in prediabetics was the "Mediterranean diet."
   d. The Mediterranean diet also showed a significant decrease in the percentage of established diabetics from needing insulin in the future and significant benefit in reducing cardiovascular events.
3. Other principles:
   a. Modest sodium restriction to 2400 to 3000 mg/day. If hypertension is present, restrict to <2400 mg/day; if nephropathy and hypertension are present, restrict to <2000 mg/day.
   b. Moderation of alcohol intake recommended (≤2 drinks/day in men, ≤1 drink/day in women).
   c. Nonnutritive artificial sweeteners are acceptable in moderate amounts.
      (1) However, it has been shown that artificial sweeteners may actually increase insulin resistance by affecting the action of insulin at receptor level.

- Exercise: Increases the cellular glucose uptake by increasing the number of

insulin receptors. The following points must be considered:

1. Exercise program must be individualized and built up slowly. Consider beginning with 15 min of low-impact aerobic exercise 3 times per wk and increasing the frequency and duration to 30 to 45 min of moderate aerobic activity (50% to 70% of maximum age predicted heart rate) to 3 to 5 days/wk.
   a. In the absence of contraindications, resistance training three times per wk should be encouraged.
2. Insulin is more rapidly absorbed when injected into a limb that is then exercised, and this can result in hypoglycemia.
3. Physical activity can result in hypoglycemia if medication dose or carbohydrate consumption is not modified. Ingestion of additional carbohydrates is recommended if pre-exercise glucose levels are <100 mg/dl.
4. Diabetes prevention program: Low-fat diet with exercise reduced diabetes by 58%. This encompassed diet of 1200 to 1800 kcal/day <30% from fat, exercise unsupervised and supervised, akin to brisk walking >150 min/wk of moderately intensity physical activity.

- Weight loss: To ideal body weight if the patient is overweight. Recent trials have shown that although weight loss has many positive health benefits for people with type 2 DM, such as slower decline in mobility, it does not reduce the number of cardiovascular events.
- Screening for nephropathy, neuropathy, and retinopathy: Annual serum creatinine and urine albumin excretion; initial comprehensive eye examination and at least annually thereafter.
- Diabetes self-management education: Could also address psychosocial issues.
- Self-monitoring of blood glucose should occur three to four times per day for patients using multiple insulin injections or on insulin pump therapy.
- Perform HbA_{1c} at least two times a yr in patients who are meeting treatment goals and who have stable glycemic control.
  1. HbA_{1c} quarterly in patients whose therapy has changed or who are not meeting glycemic goals.
  2. The HbA_{1c} goal for nonpregnant adults in general is <7%.
  3. In the elderly, those with comorbidities, or those at risk for complications from hypoglycemia, a more moderate glycemic target (HbA_{1c} 7-8) may be appropriate.
  4. In elderly patients (>80 yr of age) with average life expectancy of 5 yr, a target HbA_{1c} <8.0 is reasonable. In patients >80 yr with comorbidities and life expectancy of 3 yr, a target HbA_{1c} of <9.0 may be appropriate.

GENERAL Rx

- Type 1 DM: Lifelong insulin therapy is required for persons with type 1 DM. It should consist of basal coverage, prandial coverage, and supplemental insulin for correction of hyperglycemia. Initial total insulin dosing ranges from 0.4 to 1.0 U/kg/day, 50% of which is basal insulin and 50% prandial insulin.
- Type 2 DM: When the previous measures fail to normalize the serum glucose, oral hypoglycemic agents should be added to the regimen in T2DM. Treatment options in patient with type 2 diabetes should be tailored to try to target core diabetic defects and apply therapies that lower HbA_{1c} in a weight-neutral or weight-lowering fashion if possible; of course, cost of therapies needs to be considered as well.
- **Metformin:** The primary mechanism of metformin is to decrease hepatic glucose production and improve insulin sensitivity. Because metformin does not produce hypoglycemia when used as a monotherapy, it is preferred initially for most patients. Metformin reduces mean HbA_{1c} level by 1.1%. It is contraindicated in patients with severe renal insufficiency with an estimated glomerular filtrate rate <30 ml/min, serum creatinine level of 1.5 per dl or greater in men or 1.4 per dl or greater in women, heart failure, or other clinical states of hypoperfusion, and in patients with significant liver disease. Starting metformin in patients with GFR between 30 and 45 ml/min is also not recommended. Renal dosing of metformin is preferred, based on GFR levels rather than creatinine levels. When metformin alone does not achieve the desired A_{1C} goal, the choice of a second drug is dictated by the comorbidities or cost. For example, an SLGT2 inhibitor is preferred in patients with heart failure or cardiovascular disease.
  1. When the HbA_{1c} level is 9% or greater, initial dual-regimen combination therapy should be considered. It is important to consider that some drug classes provide benefit in cardiovascular and renal outcomes that may be independent of glucose control. Clinicians should consider adding either a GLP-1 agonist or an SGLT-2 inhibitor to metformin to improve glycemic control when a dual regimen is considered.
- **GLP-1 agonists:** Exenatide, dulaglutide, semaglutide, lixisenatide, and liraglutide are glucagon-like peptide-1 (GLP-1) agonists. These injectable agents are incretin mimetics that stimulate release of insulin from pancreatic beta cells and can be used as adjunctive therapy for patients with T2DM. GLP-1 agonists are not indicated in T1DM and are contraindicated in patients with severe renal impairment. Advantages are weight loss, no hypoglycemia when used as monotherapy and reduced incidence of cardiovascular events and nephropathy. Side effects include injection site reactions, GI side effects (nausea, diarrhea, vomiting), increased risk of pancreatitis and thyroid C-cell carcinoma. Cost is a barrier to their use.
- **Sodium-glucose co-transporter 2 ($SGLT_2$) inhibitors** (e.g., canagliflozin, dapagliflozin, empagliflozin) are useful for oral treatment of type 2 DM. By inhibiting $SGLT_2$, these medications decrease glucose reabsorption, increase urinary glucose excretion, and lower blood glucose levels (decrease HbA_{1c} by 0.7%). Empagliflozin has been shown to slow progression of renal disease in type 2 diabetics with CVD. Potential advantages include weight loss (up to 3.5% of BMI) and mild lowering of blood pressure (2 to 4 mm Hg). Side effects include increased risk of genital mycotic infections, UTIs, and volume depletion. Renal function should be evaluated before starting $SGLT_2$ inhibitors and periodically thereafter. Temporary discontinuation of these meds is recommended in cases of reduced oral intake or fluid loss. Higher cost and limited drug formulary availability are limiting factors.
- **DPP-4 inhibitors:** Sitagliptin, saxagliptin, vildagliptin, alogliptin, and linagliptin inhibit the enzyme DPP-4, responsible for inactivation and degradation of glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP). These drugs, known as "DPP-4 inhibitors" or "gliptins," raise blood incretin levels, thereby inhibiting glucagon release and lowering blood glucose levels. When used with metformin, they do not cause hypoglycemia. They have modest efficacy (hemoglobin A_{1C} reductions of 0.5% to 1%, neutral effect on weight). Linagliptin does not require a dosage adjustment in renal insufficiency. Cost is a major barrier to their use. Sitagliptin can be used in any degree of kidney disease but needs to be dosed based on GFR and creatinine levels.
- **Sulfonylureas:** Sulfonylureas increase insulin secretion and work best when given before meals. All sulfonylureas are contraindicated in patients who are allergic to sulfa. Use of sulfonylureas confers a greater risk of hypoglycemia than the other agents. These agents are now being considered to be used as last or later resort or when cost is of major concern for the patient and when other therapies cannot be incorporated or are contraindicated.
- **Acarbose and miglitol:** These agonists inhibit pancreatic amylase and small intestinal glucosidases, thereby delaying carbohydrate absorption in the gut and reducing associated postprandial hyperglycemia. The major side effects are flatulence, diarrhea, and abdominal cramps.
- **The meglitinides nateglinide and repaglinide and the bile acid sequestrant colesevelam** can also be used to lower glucose levels but are expensive and generally poorly tolerated.
- **Pramlintide** is a synthetic analog of human amylin, which is synthesized by pancreatic

TABLE 6 Onset, Peak, and Duration of Action of Currently Available Insulin Preparations

Insulin Preparation	Onset of Action	Peak Action	Duration of Action
Lispro	5-15 min	1-2 h	4-6 h
Aspart	5-15 min	1-2 h	4-6 h
Glulisine	5-15 min	1-2 h	4-6 h
Regular	30-60 min	2-3 h	6-10 h
NPH	2-4 h	4-10 h	12-18 h
Detemir	2 h	Relatively peakless	12-24 h
Glargine	2 h	Relatively peakless	20-24 h
Degludec	2 h	Relatively peakless	33-42 h

From Parrillo JE, Dellinger RP: *Critical care medicine: principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

beta cells and cosecreted with insulin in response to food intake. It suppresses glucagon secretion and slows stomach emptying and can be used as an adjunctive treatment for patients with T1DM or T2DM who inject insulin at mealtime. Nausea is its major side effect. This therapy has been largely replaced with use of GLP-1 analogs.

- **Thiazolidinediones (pioglitazone and rosiglitazone)** increase insulin sensitivity and have been used in the therapy of type 2 diabetes. Serum transaminase levels should be obtained before starting therapy and monitored periodically. Thiazolidinediones, in general, result in moderate weight gain and increase the risk for heart failure and osteoporosis/fractures. Rosiglitazone has an FDA black box warning for heart failure exacerbations and myocardial ischemia. Pioglitazone and rosiglitazone cause increased incidence of bladder cancer. Use thiazolidinediones with caution with calcium channel blockers, especially amlodipine (can cause fluid retention and edema).
- Combination therapy of various hypoglycemic agents is commonly used when dual therapy results in inadequate glycemic control.
  1. **Insulin** is indicated for the treatment of all T1DM and for T2DM patients whose condition cannot be adequately controlled with diet and oral agents. The American College of Endocrinology and the American Association of Clinical Endocrinologists recommend initiation of insulin therapy in patients with type 2 diabetes and an initial HbA_{1c} level >9%, or if the diabetes is uncontrolled despite optimal oral glycemic therapy. Insulin therapy may be initiated as augmentation, starting at 0.1 to 0.2 unit/kg of body weight, or as replacement, starting at 0.6 to 1.0 unit/kg. Table 6 summarizes onset, peak, and duration of action of currently available insulin preparations. The risks of insulin therapy include weight gain, hypoglycemia, and in rare cases, allergic or cutaneous reactions.
  2. Replacement insulin therapy should mimic normal release patterns.
     a. Approximately 50% to 60% of daily insulin can be given as a long-acting insulin (NPH, Ultralente, glargine, detemir) injected once or twice daily.
     b. The remaining 40% to 50% can be short-acting (regular) or rapid-acting (lispro, aspart, glulisine) to cover mealtime carbohydrates and correct increased current glucose levels.
     c. NPH and older basal insulins can be mixed with rapid-acting insulins like Humalog and regular; all newer basal insulins cannot be mixed in one syringe.
     d. Basal-bolus regimens are now preferred on injection of long-acting basal at bedtime or in AM to target fasting glycemia between 80 and 130, and rapid-acting mealtime insulins to target lower postprandial blood glucose <140 mg/dl.
     e. New combinations of basal insulins with GLP-1 analogs are now available:
        (1) Soliqua: Combines glargine insulin and lixisenatide in one pen. Patients taking <30 units start at 15 units and patient taking >30 units start at 30 units and are titrated every 3 to 4 days until fasting blood glucose levels are between 80 and 130 mg/dl. One should not exceed 60 units of glargine insulin.
        (2) Xultophy 100/3.6 is degludec insulin and liraglutide combination in one pen. Dosing is based on Tresiba dose. Patients start at 16 units and increase by 2 units every 5 to 7 days to target fasting glycemia between 80 and 130 mg/dl, and dose cannot exceed 50 units. The use of this combination may eliminate or reduce prandial insulin needs and limits weight gain caused by insulin.
- Continuous subcutaneous insulin infusion (CSII, or insulin pump) provides comparable or slightly better control than multiple daily injections. It should be considered for diabetes presenting in childhood or adolescence and during pregnancy. The guidelines for insulin pump therapy from the American Association of Diabetes Educators include "frequent and unpredictable fluctuations in blood glucose" and "patient perceptions that diabetes management impedes the pursuit of personal or professional goals." Use of insulin pumps are today coupled with CGM monitoring and with software in which the computer is making the automatic adjustments to glucose levels, constituting what is referred to as an "artificial pancreas." This allows for fewer fluctuations of glycemia.
- Antiplatelet therapy: Low-dose aspirin (ASA; 81 mg/day) has been proven to lower the risk of subsequent myocardial infarction, stroke, or vascular death in secondary prevention studies. The ADA recommends low-dose aspirin for primary prevention in diabetic patients with one additional cardiovascular risk factor, including age older than 50 yr, cigarette smoking, hypertension, obesity, albuminuria, hyperlipidemia, and family history of coronary artery disease. Clopidogrel can be used in patients with atherosclerotic cardiovascular disease (ASCVD) and a documented aspirin allergy. The ADA does not recommend aspirin therapy in diabetics younger than 50 yr of age at low risk for coronary artery disease.
- Lipid management: Measure fasting lipid profile at least annually in adults.
  1. All patients with diabetes with one or more additional risk factors for CVD should be on statin therapy together with lifestyle modification regardless of baseline lipid levels.
  2. Diabetic patients aged 40 to 75 with LDL cholesterol of 70 to 189 mg/dl and without clinical ASCVD should receive at least moderate-intensity statin therapy and consider high-intensity statin therapy if 10-yr ASCVD risk is ≥7.5%.
  3. Ezetimibe can be added to moderate-intensity statin therapy in those who cannot tolerate high-intensity statin therapy.
  4. Combination therapy with statin and fenofibrate is not recommended but may be considered in those with triglyceride levels equal or greater than 204 mg/dl. If triglycerides are not at goal with combination of statin and fibrate, then prescription fish oil is advised if triglyceride levels still exceed 300 mg/dl.
  5. PCK-9 inhibitors may be considered in diabetics with CAD risk when statins are insufficient and in those who cannot tolerate statins, have had cardiovascular events, and cannot achieve A_{1c} to target goal.
- Hypertension: Antihypertensive therapy is recommended to keep systolic blood pressure (BP) <140 and diastolic BP <90 mm Hg. Use of angiotensin-converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARBs) to decrease albuminuria and for prevention of progression of kidney disease should be considered regardless of presence of hypertension. Combination

BOX 2 Sick Day Management Protocol for Diabetic Patients

Examples of "Sick Day" Scenarios
- Feeling sick or presence of fever for 2 days or longer without getting better
- Vomiting or diarrhea for more than 6 h

Management

General Measures
- Check blood sugar levels at least every 4 h, but when values are changing quickly, check more often.
- Check urine or blood ketones.
- Modify usual insulin regimen according to a plan developed by the diabetes physician or team.
- Maintain adequate food and fluid intake. If your appetite is poor, aim for consumption of 50 g of carbohydrate every 3-4 h. If you are nauseous, high-carbohydrate liquids, such as regular (not diet) soft drinks or juice, or frozen juice bars, sherbet, pudding, creamed soups, or fruit-flavored yogurt usually are tolerated. Broth also is a good alternative.

Taking Medications When You Are Sick
- If you are eating: Continue taking your pills for diabetes or your insulin. Your blood sugar may continue to rise because of your illness.
- If you are nauseous or vomiting or otherwise cannot take your medicines:
  - Continue to take your long-acting insulin (Lantus, Levemir, NPH).
  - Call your doctor and discuss whether you need to adjust your short- or rapid-acting insulin dose (regular, lispro [Humalog], aspart [Novolog], glulisine [Apidra]) or your other diabetes medicines.

Examples of When to Call Physician or Diabetes Team
- If glucose levels are higher than 240 mg/dl despite taking extra insulin according to a sick day plan
- If you take diabetes pills and blood sugar is still above 240 mg/dl before meals and remains there for more than 24 h
- If symptoms/signs develop that might signal diabetic ketoacidosis or dehydration, such as dizziness, trouble breathing, fruity breath, or dry and cracked lips or tongue

From Parrillo JE, Dellinger RP: *Critical care medicine: principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

therapy with an ACE inhibitor and an ARB should be avoided due to increased risk of adverse effects among patients with diabetic nephropathy. In older adults a treatment goal of <130/70 mm Hg is not recommended due to higher mortality and morbidity.
- Bariatric surgery should be considered in adults with BMI >35 kg/m2 and type 2 diabetes, especially if the diabetes is difficult to control with lifestyle and pharmacologic therapy. Five-yr outcome data showed that, among patients with type 2 DM and a BMR of 27 to 43, bariatric surgery plus intensive medical therapy was more effective than intensive medical therapy alone in decreasing, or in some cases resolving, hyperglycemia.[2]
- Treat hypoglycemia in a conscious person with glucose tab or gel 15 to 20 g, and intramuscular injection of glucagon if unconscious. Patient and family members should be instructed on the administration of glucagon for individuals at significant risk for severe hypoglycemia. A sick day management protocol for diabetic patients is described in Box 2.

DISPOSITION

- Diabetic retinopathy occurs in nearly 15% of patients with diabetes after 15 yr of diagnosis and increases 1%/yr after diagnosis. Glycemic, lipid, and blood pressure controls are essential to reduce the risk and progression of diabetic retinopathy. An annual comprehensive eye exam by an ophthalmologist or optometrist should begin at the time of diagnosis for those with T2DM and after 5 yr in those with T1DM. Retinal laser photocoagulation and vitrectomy are effective treatment modalities. Prevention is best accomplished by strict glucose and BP control. Early blockade of the renin-angiotensin system has been shown to slow progression of retinopathy in patients with type 1 diabetes.
- The frequency of neuropathy in patients with type 2 diabetes approaches 70% to 80%. It can be subdivided into sensorimotor neuropathy and autonomic neuropathy. Duloxetine, a selective serotonin and norepinephrine reuptake inhibitor, is effective and FDA approved for relief of diabetic peripheral neuropathy. Pregabalin and gabapentin (900 to 3600 mg/day) are also effective for the symptomatic treatment of peripheral neuropathic pain. Topical capsaicin, 5% lidocaine transdermal patches, amitriptyline, and carbamazepine are also modestly effective. Use of high-dose vitamin combination of B_{12}, B_6 with alpha lipoic acid may help with nerve preservation and worsening of neuropathy, but will have no immediate effect on pain.
- Diabetic gastroparesis is most often seen in patients who have had diabetes for at least 10 yr and typically have retinopathy, neuropathy, and nephropathy. Major manifestations are postprandial fullness, nausea, vomiting, and bloating. Pharmacologic therapy involves prokinetic agents (metoclopramide). Endoscopic injection of botulinum toxin into the pylorus and gastric electrical stimulation (using f electrodes placed laparoscopically in the muscle wall of the stomach antrum and connected to a neurostimulator) represent newer approaches to nonpharmacologic therapy.
- Nephropathy: The first sign of renal involvement in patients with DM is most often microalbuminuria, which is classified as incipient nephropathy. Before the current period of intensive glycemic control and blood pressure with ACE inhibitors and angiotensin receptor blockade, it was suggested that 25% to 45% of diabetic patients would develop clinically evident renal disease (proteinuria) and 4% to 17% would progress to end-stage renal disease. In the current era of intensive glycemic and blood pressure control and ACE/ARB use, clinically evident diabetic nephropathy has declined to 9% and end-stage renal disease 2% to 7%. Use of ACE inhibitor or ARB is not recommended in diabetics with normal blood pressure, no microalbuminuria (urine albumin to creatinine ratio less than 30 mg/g creatinine) and normal renal function (eGFR >60 ml/min/1.73 m^2).
- Infections are generally more common in patients with diabetes because of multiple factors, such as impaired leukocyte function, decreased tissue perfusion secondary to vascular disease, repeated trauma because of loss of sensation, and urinary retention secondary to neuropathy.
- Prevention/delay of type 2 diabetes: Patients with prediabetes should achieve weight loss of 5% to 10% of body weight and increase physical activity to at least 150 min/wk of moderate activity such as walking. Metformin therapy may be considered in those at high risk, especially if they have hyperglycemia (HbA_{1c} ≥6) despite lifestyle interventions.
- The Mediterranean diet has been shown to prevent type 2 diabetes in patients with prediabetes and can delay the need of insulin use in type 2 diabetes in up to 50% of patients.
- Use of metformin in prediabetics can prevent onset of diabetes in up to 30% of patients, independent of diet.

REFERRAL

- Patients with diabetes should be advised to have annual ophthalmologic examinations. In T1DM, ophthalmologic visits should usually begin 5 yr after diagnosis, whereas T2DM patients should be seen from disease onset.
- Podiatric care can significantly reduce the rate of foot infections and amputations in patients with DM. Noninfected neuropathic foot ulcers require debridement and reduction of pressure.

[2]Schauer PR et al: Bariatric surgery versus intensive medical therapy for diabetes—5-year outcomes, *N Engl J Med* 376(7):641-651, 2017.

- Nephrology consultation in all cases of proteinuria, hyperkalemia, uncontrolled BP, and when GFR has decreased to <30 ml/min/1.73 m^2.

PEARLS & CONSIDERATIONS

COMMENTS

- Because normalization of serum glucose level is the ultimate goal, every patient with diabetes should measure his or her blood glucose with commercially available glucometers unless contraindicated by senility or blindness.
- Continuous glucose monitoring is now commercially available for all types of diabetics on multiple daily injections of insulin. In the near future there will be weekly disposable sensors that can replace fingersticks. The advantage of CGM is that it not only gives a patient a value, but it shows a rate of change at that moment and predicts impending hyperglycemia or hypoglycemia, allowing a patient to react appropriately.
- Underinsured children and those with psychiatric illness are at greater risk for acute complications in T1DM and require frequent monitoring and aggressive risk management with diet, exercise, and periodic laboratory evaluation.
- Significant sustained weight loss using bariatric surgery has been reported as effective in achieving remission of type 2 diabetes in morbidly obese patients. Bariatric surgery may be considered for adults with BMI >35 kg/m2 and T2DM, especially if diabetes or associated comorbidities are difficult to control with lifestyle and pharmacologic therapy.
- Cigarette smoking predicts incident type 2 diabetes. For a smoker at risk for diabetes, smoking cessation should be coupled with strategies for diabetes prevention and early detection.
- Glycemic control in hospitalized patients: The American College of Physicians (ACP) recommends against using intensive insulin therapy to strictly control blood glucose in nonsurgical intensive care unit (SICU)/medical intensive care unit (MICU) in patients with or without DM. The ACP recommends a target blood glucose level of 130 to 180 mg/dl if insulin therapy is used.
- Studies have shown that tight glycemic control in SICU patients can reduce infection rates and ICU stay. This was not seen in MICU patients. However, there is evidence showing that patients using continuous IV insulin infusions to keep tight glycemic control after open heart surgery reduces sternal wound infection rates.
- Now many institutions are incorporating automated log adjustment, such as Glucommander, which reduces workload of staff in maintaining smooth glycemic control.

BASIC INFORMATION

DEFINITION

Diabetic foot infections (DFIs) are a common and potentially serious problem in persons with diabetes. They usually arise from either a skin ulceration that occurs secondarily to peripheral neuropathy or in a wound caused by some form of trauma. The infection usually involves one or more bacteria and can spread to contiguous tissues including bone, causing an osteomyelitis.

SYNONYMS

Diabetic foot ulcer
Diabetic foot infection
DFI

ICD-10CM CODES

E10.5	Diabetes mellitus with peripheral circulatory complications
E10.6D	Diabetes mellitus with other specific complications
E11.621	Type 2 diabetes mellitus with foot ulcer

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: DFIs are the most common cause of hospitalizations for diabetic patients. They account for 20% of all hospital admissions. Nearly one in six patients will die within 1 yr of their infection.

PEAK INCIDENCE: More common in Hispanics, African Americans, and Native Americans due to increased rates of diabetes in those populations

PREVALENCE: 25 million people in the U.S. have diabetes, of which 19% to 34% will develop a foot ulcer in their lifetime and more than 50% of these will become infected.

PREDOMINANT SEX AND AGE: Females greater than males

RISK FACTORS:

- Diabetes greater than 10 yr
- Poor glucose control
- Peripheral neuropathy: Altered protective sensation and altered pain response
- Diabetic angiopathy: Atherosclerotic obstruction of larger vessels leading to peripheral vascular disease
- Evidence of increased local pressure: Callus or erythema

PHYSICAL FINDINGS & CLINCIAL PRESENTATION

- Based on guidelines by Infectious Diseases Society of America, infection is present if obvious purulent drainage and/or the presence of two or more signs of inflammation:
  1. Erythema
  2. Pain
  3. Tenderness
  4. Warmth
  5. Induration
- Systemic signs of infection include:
  1. Anorexia, nausea/vomiting
  2. Fever, chills, night sweats
  3. Change in mental status and recent worsening of glycemic control

An earlier and commonly used classification system was originally proposed by Wagner.

An update to the Wagner system was introduced at the University of Texas (UT), San Antonio, U.S. While similar to Wagner in its first three categories, this later system eliminated grades 4 and 5 and added stages A-D for each of the grades. The UT system was the first diabetic foot ulcer classification to be validated.

University of Texas system Grade:

- Grade 0: Pre- or postulcerative (Stages A to D)
- Grade 1: Full-thickness ulcer not involving tendon, capsule, or bone (Stages A to D)
- Grade 2: Tendon or capsular involvement without bone palpable (Stages A to D)
- Grade 3: Probes to bone (Stages A to D)

Stage:

1. A: Noninfected
2. B: Infected
3. C: Ischemic
4. D: Infected and ischemic

ETIOLOGY

- Most diabetic foot infections are polymicrobial (can involve 5 to 7 different bacteria) and depend on the extent of involvement.
- Superficial infections are likely due to gram-positive skin bacteria:
  1. *Staphylococcus aureus*, includes methicillin-resistant *S. aureus* (MRSA)
  2. *Streptococcus agalactiae* (group B streptococcus) and *Streptococcus pyogenes* (group A streptococcus)
  3. Coagulase-negative *Staphylococcus*
- Infections that are deep, chronically infected, or previously treated are likely to be polymicrobial:
  1. Include above bacteria plus enterococci, gram-negative rods including *Pseudomonas aeruginosa* and anaerobes
  2. With gangrene can expect more anaerobic bacteria such as *Clostridia* and *Bacteroides* species
  3. Patients with multiple admissions can have more resistant bacteria such as ESBL-type resistant gram-negative rod bacteria, MRSA, and *Acinetobacter*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other inflammatory conditions that can mimic diabetic foot infections include:

- Crystal-associated arthritis such as gout
- Trauma
- Acute Charcot arthropathy from long-standing diabetes
- Venous stasis ulcers
- Deep vein thrombosis

WORKUP

Evaluation of a patient with a DFI involves determining the extent and severity of the infection, identifying the underlying factors that predispose to the infection, and determining the microbiologic etiology.

PHYSICAL EXAMINATION

- Vital signs: Fever, chills, hypotension, tachycardia can be present.
- Detailed wound description: Length, width, and depth of wound, consistency of drainage, character of wound base: Granular fibrous necrotic.
- Determination of osteomyelitis: Highly likely if bone visible. A positive probe test to bone has a sensitivity of 66% and specificity of 85% in diagnosing bone infection.
- Necrotizing infections may present with cutaneous bullae, soft tissue gas, foul odor, and skin discoloration (Fig. E1).
- Severe infections may present with gangrene, tissue necrosis, and evidence of tissue ischemia (Fig. E2), all of which may be limb threatening.

LABORATORY TESTS

Important to obtain at baseline and to assess response to therapy:

- Fewer than 50% of patients have an elevated WBC.
- Determine BUN/Cr, acidosis, hemoglobin A_{1C}, and blood sugar.
- Acute phase reactants: Sed rate and CRP are markers for inflammation.
  1. Sed rate >70 increases probability of bone infection.
- Serum prealbumin and albumin are markers for nutritional status and ability to heal.
- An ulcer size larger than 2 cm^2 is indicative of osteomyelitis.
- Gram stains and cultures: Superficial cultures should not be obtained as they may contain colonizing bacteria; instead deep tissue cultures (aerobic and anaerobic) should be obtained.

IMAGING STUDIES

- Plain film x-ray evaluates bones and soft issues and can detect presence of tissue gas, which would represent an emergent situation (Fig. 3).
- Osteomyelitis appears as radiolucencies, periosteal reaction, and destructive changes. Plain films are 67% specific and 60% sensitive for osteomyelitis.
- Bone scan: Indium-111 or technetium-99 can distinguish acute and chronic infections.
- CT and MRI: MRI is the most sensitive and specific test to detect osteomyelitis and abscess formation.

OTHER DIAGNOSTIC TESTS

- Annual noninvasive vascular studies: Ankle brachial index (ABI): <0.90 or >1.30 indicates peripheral arterial disease
- Transcutaneous oxygen (TcPO2) tension measurements: Predictive of wound healing failure at levels below 25 mm Hg

TREATMENT

Empiric antibiotic regimen should be started based on likely pathogens suspected and severity of disease. Wound management and debridement including surgical consultation are important as well.

FIG. 3 X-ray. Significant soft tissue swelling in midfoot with numerous gas bubbles seen in the soft tissues.

NONPHARMACOLOGIC THERAPY

- Good nutrition will promote wound healing.
- Glycemic control will promote healing.
- Fluid and electrolyte balance will improve healing.

ACUTE GENERAL TREATMENT

WOUND MANAGEMENT:

- Debridement of callus and necrotic tissues by wound care specialist or surgeon and at times may require multiple debridements.
- Wound dressing: To absorb exudates and promote healing. Many products are available but none has been proven superior and include:
  1. Enzymes
  2. Gels
  3. Hydrocolloids
  4. Antiseptics containing iodine or silver salts
  5. Honey
- Relieve pressure on the foot: Casts or special shoes.
- Amputation or revascularization procedures such as angioplasty or bypass grafting may be necessary.

ANTIBIOTIC MANAGEMENT:

- Prior to receiving culture results an empiric antibiotic regimen should be started as soon as possible to cover skin bacteria, gram-negative rods, and anaerobes. Options for intravenous therapy include:
  1. Piperacillin-tazobactam: 3.375 g IV q6h with normal kidney function. Will cover gram-negative rods including *Pseudomonas aeruginosa*, streptococci, anaerobes, and *Staphylococcus aureus.* Adjust dose based on CrCl.
  2. Meropenem: 1 g IV q8h with normal kidney function has comparable coverage as piperacillin-tazobactam. Similar agents include imipenem and doripenem.
  3. Third-generation cephalosporin such as cefepime, 2 g IV q8h, or ceftriaxone, 2 g IV qd, have excellent gram-negative coverage, and for anaerobic coverage add metronidazole, 500 mg IV q8h, or clindamycin 900 mg IV q8h. Cefepime will cover *Pseudomonas aeruginosa* but ceftriaxone will not.
  4. For penicillin-allergic patients a combination of ciprofloxacin, 400 mg IV q12h, plus metronidazole or clindamycin is an option. Aztreonam is another option for gram-negative rod coverage, 2 g IV q8h.
  5. If MRSA is suspected, need to add IV vancomycin, 15-20 mg/kg IV q8-12h, depending on age and CrCL and follow trough levels to keep above 15. Other options include daptomycin, 4 mg/kg IV qd, which does not have to be adjusted for CrCL, or linezolid, 400-600 mg IV q12h.
  6. If VRE is suspected, options include tigecycline, 100-mg IV load dose, then 50 mg IV q12h, which also covers MRSA and gram-negative rods but not *Pseudomonas aeruginosa,* or can use daptomycin or linezolid.
  7. If ESBL gram-negative bacteria are suspected, then options include meropenem or ertapenem, 1 g IV qd, or tigecycline.
  8. Once culture results are known can tailor antibiotics to more specific agent.
- Oral antibiotics used for milder infections include amoxicillin-clavulanate, 875 mg PO q12h, which will cover gram-negative rods, streptococci, and anaerobes, or ciprofloxacin plus metronidazole or clindamycin. Bactrim will cover MRSA and MSSA and some gram-negative rods.

The expert panel on diabetic foot infection (DFI) of the International Working Group on the Diabetic Foot conducted a systematic review. Results of comparisons of different antibiotic regimens generally demonstrated that newly introduced antibiotic regimens appeared to be as effective as conventional therapy.

CHRONIC TREATMENT

- Length of therapy: Highly variable depending on the severity of the infection. In general, 2 to 4 wk of antibiotics is sufficient. If bone infection suspected or documented, may need 4 to 8 wk of antibiotics, preferably intravenous via a peripherally inserted central line (PICC line).
- Surgical debridement may also be necessary for several wk.

COMPLEMENTARY MEDICINE

- Hyperbaric oxygen (HBO): Used as an adjunct to antibiotics, debridement, and revascularization in the therapy of chronic, nonhealing wounds associated with diabetes. Evidence of effectiveness is conflicting, and recent trials have failed to show improvement in clinical outcomes.[1] HBO acts by:
  1. Inducing vasoconstriction and reducing vasogenic edema
  2. Facilitating fibroblast activity, angiogenesis, and wound healing
  3. Killing anaerobic bacteria and augmenting neutrophil bactericidal activity
- Negative pressure wound therapy (wound vac): Controlled, subatmospheric pressure applied to an open wound can accelerate healing and closure.
  1. An open cell foam insert is cut to fit the open wound and then secured under a clear, vapor-permeable, plastic dressing.
  2. Tubing extends from the sponge to a disposable collection canister.
  3. A portable pump applies 125 mm Hg of controlled suction to the system. The subatmospheric pressure (suction) is equally distributed across the open wound and evacuates stagnant fluid from the wound.

DISPOSITION

- Following up on sed rates, CRP, BUN/CR, and levels of vancomycin if that antibiotic used.
- Surgical or wound center care follow-up.
- HBO usually involves multiple sessions over several wks.
- Wound vac is applied for wks and requires periodic nursing follow-up.
- The risk of death at 5 yr for a patient with a diabetic foot ulcer is 2 to 5 times as high as the risk for a patient with diabetes without a foot ulcer.

REFERRAL

- Infectious disease consultant for antibiotic management
- Surgeon or wound care center for surgical treatments
- Endocrinologist for good diabetes care
- Vascular surgeon for angioplasty or bypass procedures

PEARLS & CONSIDERATIONS

- In a meta-analysis of randomized controlled trials on the outcome of DFIs, there was a 22.7% treatment failure rate.
- Patients should be advised to seek prompt medical attention as these infections can progress rapidly to gangrene.

Diabetic Gastroparesis

BASIC INFORMATION

DEFINITION

Gastroparesis is a syndrome characterized by delayed gastric emptying in the absence of a mechanical obstruction of the stomach. It is associated with the cardinal symptoms of nausea, vomiting, early satiety, belching, bloating, and/or upper abdominal pain. It is commonly associated with longstanding, poorly controlled diabetes.

SYNONYMS

Gastroparesis diabeticorum
Gastrointestinal autonomic neuropathy
Delayed gastric emptying

ICD-10CM CODE
K31.84 Diabetic gastroparesis

EPIDEMIOLOGY & DEMOGRAPHICS

- Age-adjusted incidence of gastroparesis is 2.4 per 100,000 person-yr for men and 9.8 per 100,000 person-yr for women. The age-adjusted prevalence of definite gastroparesis is 9.6 per 100,000 persons for men and 38 per 100,000 persons for women
- Gastroparesis is seen more commonly in women, and there is no known genetic predisposition to the disease
- There are certain risk factors for development of gastroparesis, and diabetes is the most frequently recognized systemic disease. However, the most common form is idiopathic, where no detectable primary underlying abnormality is found. The idiopathic form accounts for approximately 50% of the patients with delayed gastric emptying
- Other risk factors include:
  1. Postviral, especially Rotavirus and Norwalk virus
  2. Medications including narcotics, calcium channel blockers, and tricyclic antidepressants
  3. Postsurgical
  4. Neurologic illnesses, such as multiple sclerosis, brain stem stroke, or tumor, etc.
  5. Autoimmune gastrointestinal dysmotility
  6. Others such as mesenteric ischemia, scleroderma

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with gastroparesis present with nausea, vomiting (vomitus may contain food ingested a few hours earlier), abdominal pain, early satiety, postprandial fullness, bloating, and in severe cases, weight loss. Although abdominal pain is a frequent symptom in patients with gastroparesis, it is rarely the predominant symptom.
- Interestingly, in patients with diabetes as the cause for gastroparesis, severe retching and vomiting are more commonly reported.
- Symptoms of gastroparesis are more pronounced in patients with type 1 diabetes, as compared with patients with type 2 diabetes.
- Physical examination findings may include epigastric distention or tenderness, but not guarding or rigidity. A succussion splash may be heard on auscultation by gently rocking the patient.

ETIOLOGY

- Diabetic gastroparesis is thought to result from impairment of neural control of gastric function. Various mechanisms of nerve injury include inflammatory changes to the autonomic ganglia or dropout of myelinated fibers involving the vagus nerve.
- Acute hyperglycemia has been found to have effects on the gastric sensory and motor functions by causing altered gastric electrical activity. It can also result in relaxation of the proximal stomach and decreased pressure in the antrum and pylorus. All of these processes can contribute to the retardation of gastric emptying.
- Achieving euglycemia can correct the gastric emptying delay.
- The effect of chronic hyperglycemia on the stomach is less clear, but there is some evidence that gastric emptying of meals is slower in patients with high glycated hemoglobin levels.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gastric outlet obstruction
- Cyclic vomiting syndrome
- Chronic use of cannabinoids
- Functional dyspepsia
- Irritable bowel syndrome
- Rumination syndrome
- Eating disorders such as anorexia nervosa and bulimia

WORKUP

- Thorough history and physical examination.
  1. An associated history of poorly controlled blood sugars may be present.
  2. A history of retinopathy, nephropathy, and neuropathy may be present in association with diabetes.
- All medications that can delay gastric emptying should be stopped before formal workup.

LABORATORY TESTS

No specific labs are needed to confirm the diagnosis, but the following can help to arrive at diagnosis:

- Hemoglobin A_{1c} (HbA_{1c})
- TSH
- Total protein/albumin
- Hemoglobin
- Vitamin B_{12}
- Antinuclear antibody titers

IMAGING STUDIES

- Initial imaging should be done to rule out a mass causing mechanical obstruction.
  1. Upper GI endoscopy is first line.
  2. Computed tomography (CT) enterography vs. magnetic resonance (MR) enterography may also be done to rule out mechanical obstruction from a small-bowel mass.
  3. Barium follow-through if CT or MR enterography unavailable.
- Food retained after overnight fasting may be suggestive of gastroparesis.
- After a mechanical obstruction has been ruled out, scintigraphic gastric emptying should be done as a confirmatory test.
  1. It is the simplest and most cost-effective test.
  2. Documenting the presence of delayed gastric emptying and assessing its severity is best done by measuring the delay in gastric emptying of solids.
  3. Patient is asked to ingest a standard, low-fat meal.
  4. Abnormal gastric emptying is defined as >10% gastric retention of solid food at 4 h and/or >60% at 2 h.
- ^{13}C breath test can also be used to measure gastric emptying.
  1. Not as sensitive as the scintigraphy method
- An alternative testing modality, called the *wireless motility capsule,* is as sensitive and specific as scintigraphy, but it is rather expensive and has not been shown to offer any added clinical information that scintigraphy has already provided.
  1. It is an ingestible, wireless capsule that measures pH, pressure, and temperature as it traverses the GI tract. Gastric emptying of the capsule occurs with phase III of the migrating motor complex, signifying completion of the postprandial phase.

TREATMENT

- Diabetic gastroparesis is not progressive, and treatment is mainly directed toward alleviating patient symptoms. Exacerbating factors must be corrected as well.
- Patients can have a calorie-deficient diet, along with deficiencies in minerals and vitamins.

NONPHARMACOLOGIC THERAPY

- Nonpharmacologic therapy includes provision of nutritional support along with dietary modifications.
  1. Oral nutrition is preferred in mild disease. Diet should include small meals that are low in fiber (low-residue) and fat.
  2. Avoidance of carbonated beverages is recommended because these can lead to symptoms of bloating.
  3. Alcohol and tobacco smoking should also be stopped because these also delay gastric emptying.
  4. For patients with severe disease, a feeding jejunostomy tube may be considered. A successful trial of a nasojejunal feeding tube should precede placement.
  5. Optimize glucose and electrolyte levels.

ACUTE GENERAL Rx

- Prokinetic agents can be used to improve gastric motility.

1. Metoclopramide and erythromycin are both available in intravenous and liquid form, which makes medication administration, tolerance, and efficacy more acceptable if patient symptoms are severe.

- Antiemetic agents may also be needed for symptom relief in the acute setting.
  1. Phenothiazines, such as promethazine.
  2. 5-HT3 antagonists, such as ondansetron.
  3. Neurokinin receptor antagonist, such as aprepitant.
- Intravenous fluid resuscitation may be required if signs or symptoms of dehydration are present due to persistent nausea and vomiting.
- Correct hyperglycemia even in the acute setting, because delayed gastric emptying can be quickly corrected in the immediate setting.
- Discontinue medications that may delay gastric emptying.
  1. Pain medications.
     a. Avoid opioids.
     b. Tramadol may be used; however, one study showed that although gastric emptying was improved, colonic transit time was delayed.
  2. Incretin-based therapies and glucagon-like peptide 1 (GLP-1) analogues have been shown to retard gastric emptying.

CHRONIC Rx

- Metoclopramide should not be used for more than 12 wk unless the benefits outweigh the risks. Side effects include restlessness, anxiety, QT prolongation, and extrapyramidal effects such as dystonia and tardive dyskinesia.
- Erythromycin use is limited to 4 wk because longer use leads to tachyphylaxis. Similar effect is seen with the higher dose (250 mg) vs. a lower dose (40 mg).
- Pain management may need to be addressed for patients receiving chronic opioids.
  1. Low-dose tricyclic antidepressants (TCAs), selective serotonin reuptake inhibitors (SSRIs), and pregabalin can be used as alternatives for long-term pain control.
- Endoscopic intrapyloric injection of botulinum toxin may be considered.
  1. Not shown to improve symptoms associated with diabetic gastroparesis but does have a modest effect on improving gastric emptying.
  2. Not approved as a mainstay treatment modality.
- Gastric electrical stimulation via a gastric electrical neurostimulator can be offered to patients with diabetic gastroparesis.
  1. Shown to improve symptom severity and gastric emptying.
  2. Approved as a humanitarian exemption device for patients with refractory symptoms.
- Surgical intervention.
  1. Venting gastrostomy, gastrojejunostomy, pyloroplasty, and gastrectomy are available.
  2. Rarely employed and is reserved for patients with severe, debilitating disease.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Dietary modifications as described earlier
- Acupuncture
- Autonomic retraining

PEARLS & CONSIDERATIONS

COMMENTS

- Gastroparesis can be one of the consequences of chronic, poorly controlled diabetes.
- Symptoms of nausea, vomiting, bloating, early satiety, and abdominal pain in a patient with chronic, poorly controlled diabetes should prompt the possibility of gastroparesis.
- The diagnostic study of choice is gastric scintigraphy, performed by the nuclear medicine department.
- Discontinue all medications that can slow gastric emptying, especially opioids.
- Improve blood sugar control and avoid hyperglycemia.
- Antiemetics with prokinetic properties, such as metoclopramide, are most helpful in relieving nausea and vomiting, in both the acute and chronic presentations.
- Refer to gastroenterology for consideration of botulinum toxin injection or gastric neurostimulator placement if patients have poorly controlled and refractory disease.

PREVENTION

Focus on improved glycemic control in the long term.

PATIENT & FAMILY EDUCATION

- Gastroparesis Patient Association for Cures and Treatments (G-PACT)
- Association of Gastrointestinal Motility Disorders, Inc. (AGMD)

Diabetic Ketoacidosis

BASIC INFORMATION

DEFINITION

Diabetic ketoacidosis (DKA) is a life-threatening complication of diabetes mellitus (DM). It results from an absolute or relative insulin deficiency that results in insulin resistance when paired with counterregulatory hormone and free fatty acid excess. DKA is characterized by the presence of an anion gap metabolic acidosis, ketonemia, and hyperglycemia.

ICD-10CM CODES

E10.10	Type 2 diabetes mellitus with other specified complication
E10.11	Diabetic ketoacidosis with coma associated with type 1 diabetes mellitus
E08.10	Diabetes mellitus due to underlying condition with ketoacidosis without coma
E08.11	Diabetes mellitus due to underlying condition with ketoacidosis with coma
E13.10	Diabetic ketoacidosis
E13.11	Diabetic ketoacidosis with coma

EPIDEMIOLOGY & DEMOGRAPHICS

DKA is the most common hyperglycemic emergency among patients with type 1 (T1D) and type 2 diabetes (T2D). The reported number of DKA hospitalizations in the United States is >140,000/yr. DKA most commonly occurs in T1D, with one-third in T2D. Those with ketosis-prone T2D are especially vulnerable. Overall, DKA prevalence has increased, yet mortality has decreased to <5%, significantly less than from hyperglycemic hyperosmolar syndrome (HHS). Mortality from DKA in children and adolescents is most commonly due to cerebral edema, whereas in adults it is usually related to the precipitating illness (i.e., sepsis, cardiac or CNS ischemia, pneumonia).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Polyuria, polydipsia, weight loss, weakness
- Signs of dehydration (tachycardia, hypotension, dry mucous membranes, sunken eyes, poor skin turgor)
- Nausea, vomiting, abdominal tenderness, ileus
- Mental obtundation (can range from full alertness to coma)
- Tachypnea with air hunger (Kussmaul respirations)
- Fruity breath (caused by acetone)
- Evidence of precipitating factors (i.e., ischemia or infection)

ETIOLOGY

Hyperglycemia occurs from relative insulinopenia for the degree of transient insulin resistance plus increased hepatic gluconeogenesis and glycogenolysis. The resulting lipolysis and fatty oxidation produce ketonemia and metabolic acidosis.

DKA can be precipitated by various conditions:

- Infection
- Insulin deficiency (undiagnosed diabetes, medication nonadherence/inadequacy, insulin pump malfunction/disconnect, diabulimia)
- Inflammatory conditions (i.e., acute pancreatitis)
- Ischemia/infarction (i.e., myocardial infarction, stroke, bowel ischemia)
- Severe extracellular fluid volume depletion
- Drugs (i.e., steroids, thiazides, atypical antipsychotics, SGLT2 inhibitors, alcohol, sympathomimetics including cocaine, cancer immunotherapy [such as anti-programmed death 1 {PD-1} antibody treatment])

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hyperosmolar nonketotic state
- Alcoholic/starvation ketoacidosis
- Lactic acidosis
- Acute kidney injury/chronic kidney disease
- Metabolic acidosis caused by exogenous poisons, e.g., methanol, ethylene glycol, paraldehyde
- Salicylate poisoning
- Hypovolemic or septic shock

WORKUP

After initial history is obtained, perform physical examination, including evaluation of airway, breathing, circulation, mental status, volume status, and signs suggestive of precipitating event(s).

LABORATORY TESTS

- Serum glucose level: Generally >250 mg/dl. However, "euglycemic DKA" can occur in 10% of the DKA population (i.e., exogenous insulin injection en route to hospital, administration of an SGLT2-inhibitor, food restriction).
- Arterial blood gas (demonstrating metabolic acidosis): Arterial pH <7.30.
- Serum beta hydroxybutyrate and urine ketones: Positive (beta hydroxybutyrate >3 mmol/L, ≥2+ urine ketones).
- Serum electrolytes:
  1. Serum bicarbonate concentration: <15 mmol/L (mild DKA may reduce levels to <18 mmol/L).
  2. Serum potassium concentration: Levels may initially measure as normal or high from extracellular shift with insulin deficiency and hyperosmolality. However, overall total body potassium depletion occurs from urinary losses and vomiting.
  3. Serum sodium concentration: May be low, normal, or high. Hyperglycemia increases plasma osmolality, which attracts intracellular water to the extracellular compartment and decreases the sodium level. Correct the serum sodium concentration: Add 1.6 mmol/L to the measured serum sodium level for every 100 mg/dl increase of serum glucose >100 mg/dl and <400 mg/dl, and then increase the sodium level by 4 mmol/L for each glucose increment of 100 mg/dl above 400 mg/dl.
  4. Serum calcium, magnesium, and phosphorus: May be significantly low and may decrease further with DKA treatment.
  5. Anion gap (AG): Na – (Cl + HCO_3). AG is increased (>10 mmol/L) from elevated ketones.
  6. Blood urea nitrogen (BUN) and creatinine: Generally reveals acute kidney injury.
- Hemoglobin A1c if not performed within the preceding 3 mo.
- Complete blood count with differential: May indicate underlying infection (leukocytosis >25,000/mm^3), inflammatory condition, or hemoconcentration. A leukocytosis of 10,000 to 15,000/mm^3 is expected from the stress of illness alone.
- Urinalysis, urine/blood cultures: As indicated based on exam findings.
- Pregnancy test: Perform in all female patients of reproductive age. DKA in pregnancy bodes significant fetal morbidity and mortality.
- Lipase/liver enzymes: Obtain if abdominal pain present. Elevated lipase can occur without underlying pancreatitis.

IMAGING STUDIES

ECG, chest x-ray, and other imaging studies as indicated to evaluate the precipitating cause(s).

TREATMENT

NONPHARMACOLOGIC THERAPY

- Monitor mental status, vital signs, and urine output hourly until improved.
- Monitor serum glucose hourly and serum electrolytes, BUN, and creatinine every 2 to 4 hours until DKA resolves.

ACUTE GENERAL Rx (FIG. 1)

FLUID REPLACEMENT: Fluid therapy is initiated to expand volume and restore renal perfusion for a typical total body water deficit of 8 to 10 L. In the absence of cardiac compromise or severe kidney impairment, infuse 0.9% normal saline (NS) at an initial rate of 1 to 1.5 L/hr (alternatively, use 15 to 20 ml/kg per hour) for the first 1 to 2 hours. The subsequent fluid choice depends on patient hemodynamics, electrolytes, and urinary output. If corrected serum sodium is normal or high, infuse 0.45% NS at 250 to 500 ml/hr. If corrected serum sodium is low, continue 0.9% NS at a similar rate. Once serum glucose decreases to 200 mg/dl, add 5% dextrose to the IV fluid. The recommended sodium decline is 0.5 mmol/L per hour and should not surpass 10 to 12 mmol/L per day. Hyperglycemia (>250 mg/dl) resolves sooner than ketoacidosis (6 versus 12 hours, respectively).

INSULIN ADMINISTRATION: Administer initial bolus of IV regular insulin 0.1 units/kg followed by 0.1 units/kg per hour infusion or a continuous infusion of 0.14 units/kg per hour without initial bolus. If the serum glucose declines to <50 to 75 mg/dl in the first hour, increase insulin infusion rate hourly until a steady glucose decline is seen. After the serum glucose reaches 200 mg/dl and until DKA resolves, maintain the serum glucose concentration between 150 and

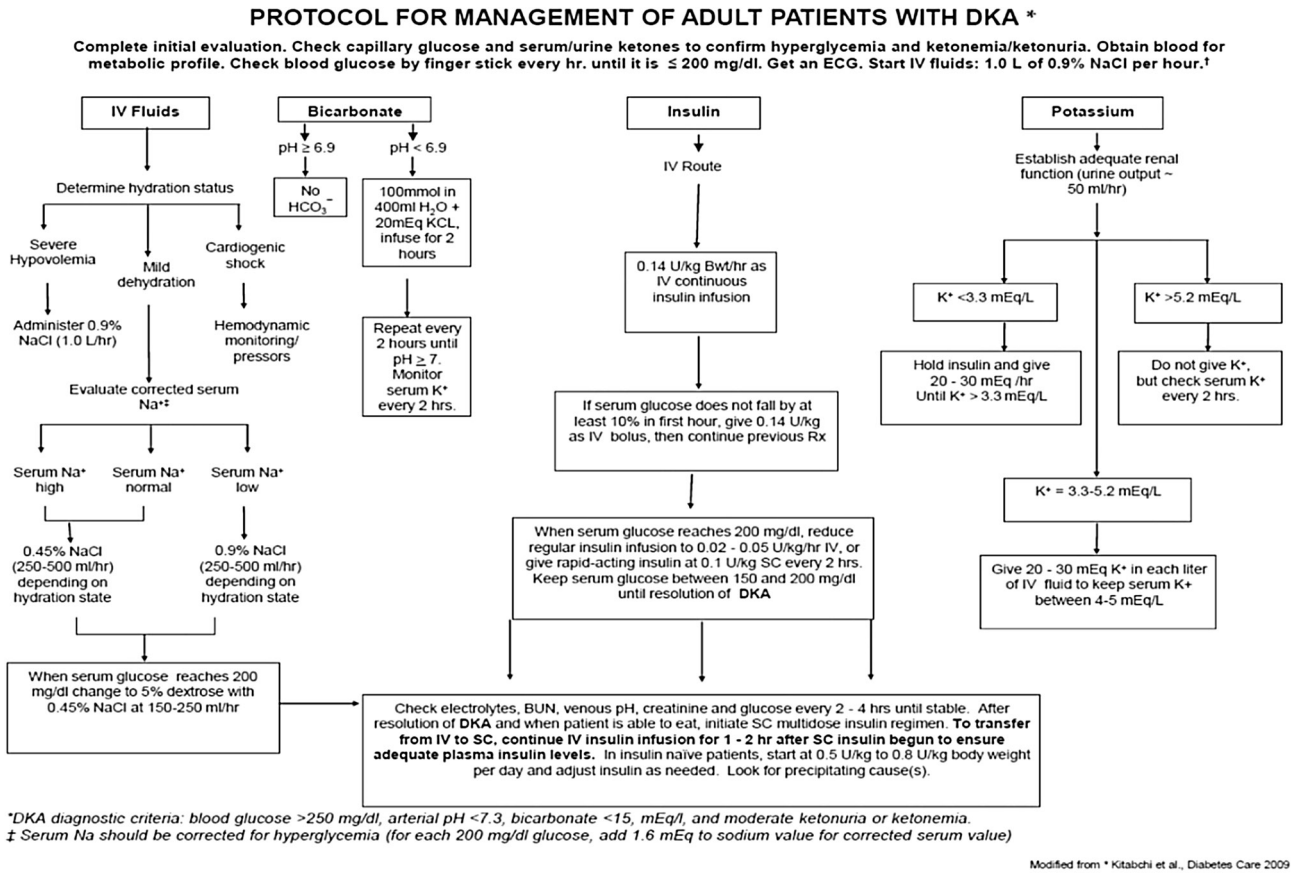

FIG. 1 Management of diabetic ketoacidosis. (From Nyenwe EA et al: The evolution of diabetic ketoacidosis: an update of its etiology, pathogenesis, and management, *Metabolism* 65(4):507-521, 2016.)

200 mg/dl by decreasing the insulin infusion to 0.02 to 0.05 units/kg per hour or deliver subcutaneous rapid-acting insulin at 0.1 units/kg every 2 hours.

POTASSIUM REPLACEMENT: Insulin therapy shifts potassium intracellularly, frequently causing hypokalemia. If the serum potassium concentration at presentation is between 3.3 and 5.2 mmol/L, infuse 20 to 30 mmol of potassium chloride (KCl) with each liter of IV fluid to maintain serum potassium at 4 to 5 mmol/L. If serum potassium is <3.3 mmol/L, withhold insulin until the serum potassium level is >3.3 mmol/L, and replace potassium by administering KCl infusion at 20 to 30 mmol/hr. If the serum potassium level at presentation is >5.2 mmol/L, monitor the level every 2 hours without replacement.

BICARBONATE REPLACEMENT: The administration of bicarbonate in DKA is generally not recommended. Bicarbonate does not improve time to resolution of acidosis or discharge, although adverse effects are associated with severe metabolic acidosis (decreased cardiac contractility, cerebral vasodilation). In adult patients with pH <6.9, administer 100 mmol (2 ampules) of sodium bicarbonate in 800 ml of sterile water (isotonic solution) with 20 mmol KCl at 200 ml/hr for 2 hours until venous pH is >7.0. If pH is still <7 after infusion, repeat infusion every 2 hours until pH is >7.

PHOSPHATE REPLACEMENT: Phosphate replacement is not routinely recommended, although phosphorus concentrations decrease with insulin administration. In patients with cardiac dysfunction, respiratory depression, or anemia and serum phosphorus <1 mg/dl, add 20 to 30 mmol/L of potassium phosphate to IV fluids to prevent diaphragmatic muscle weakness.

TRANSITION TO SUBCUTANEOUS INSULIN: Resolution of DKA occurs when blood glucose is <200 mg/dl and two of the following occur: Venous pH >7.3, serum bicarbonate >15 mmol/L, anion gap ≤12 mmol/L. At this point, patients can transition to subcutaneous insulin but may remain on IV insulin if NPO. Subcutaneous intermediate- or long-acting insulin should be overlapped with IV insulin by 2 to 4 hours to maintain adequate insulin levels and prevent rebound hyperglycemia. In patients with a known history of controlled diabetes, their home insulin regimens may be resumed. In patients with known poorly controlled diabetes, the subcutaneous insulin dose can be determined based on stable insulin drip requirements. Insulin-naïve patients may be started on basal-bolus insulin therapy by calculation of total daily dose of 0.5 to 0.8 units/kg (split as half-basal and half-bolus; administer one third of total bolus for each meal) or by stable insulin drip requirements. Further subcutaneous insulin dose titration is based on blood glucose results. Resolution of glucotoxicity and the inciting condition(s) will decrease insulin requirements.

DISPOSITION: In general, patients with DKA should be admitted to an intensive care unit with an insulin infusion. Alert patients who are able to ingest fluids orally and have mild DKA (plasma glucose >250 mg/dl, arterial pH 7.25 to 7.3, bicarbonate 15 to 18 mmol/L with anion gap >10 mmol/L, and alert mental status) may be treated with rapid-acting insulin analogues under observation and discharged. Timely follow-up with primary care or endocrinology is important, preferably with an appointment made before discharge.

PEARLS & CONSIDERATIONS

COMMENTS

- DKA is the initial presentation of diabetes in 15% to 20% of adults and 30% to 40% of children. This underscores the importance of educating patients, families, and school administrators regarding early symptoms of diabetes with the aim of earlier diagnosis.
- DKA in end-stage renal disease (ESRD) patients is relatively uncommon secondary to decreased insulin clearance. In fact, low GFR increases the risk for hypoglycemia. However, when ESRD patients develop DKA, special management considerations are needed. These patients are usually anuric and do not produce an osmotic diuresis, negating the need for aggressive volume repletion. Vigorous volume resuscitation may lead an

ESRD patient to volume overload, pulmonary edema, and respiratory distress. Anuric ESRD patients do not have urinary potassium loss, thus making potassium replacement unnecessary. Similarly, phosphorus supplementation is not required. In fact, in severe acidosis, transcellular potassium shifts for hydrogen may produce hyperkalemia, prompting some providers to request immediate dialysis. Insulin therapy alone for hyperglycemia may also correct hyperkalemia without the need for dialysis. During DKA in ESRD patients, dialysis is generally only recommended if there are hyperkalemia-induced electrocardiographic manifestations. A precipitous drop in serum glucose from an insulin infusion and hemodialysis may result in rapid tonicity shifts, predisposing to cerebral edema. Thus, hemodialysis is typically delayed until the serum glucose is corrected. Due to increased risk for hypoglycemia, ESRD patients require careful and preemptive insulin reduction from the hospital DKA protocol.

- Address affordability of insulin before discharge. Consider use of NPH and regular insulin for as little as $25 per vial.
- Proper instructions for insulin storage, dosing, timing of mealtime insulin before meals, preparation of insulin before injection (i.e., resuspend NPH), and use of syringe/vial or pen are essential.

PREVENTION

Many cases of DKA can be prevented by effective patient education and communication. Education of patients regarding sick day management includes early communication with the health care provider, continuing insulin during illness, checking ketones, and continuing an easily digestible liquid diet that contains carbohydrates.

BASIC INFORMATION

DEFINITION

Diabetic nephropathy (DN) is chronic kidney disease defined by structural and functional changes that develop as a result of microvascular complications associated with long-standing or poorly controlled diabetes mellitus (DM). The clinical presentation includes proteinuria, hypertension (HTN) and progressive reduction in renal function. This is seen histologically as glomerular basement membrane thickening, mesangial matrix expansion, foot process effacement, arteriolar hyalinosis, microaneurysms, nodular glomerulosclerosis (Kimmelstiel-Wilson nodules) and tubulointerstitial fibrosis.

SYNONYMS

Diabetic kidney disease
DN

ICD-10CM CODES

E10.21	Type 1 diabetes mellitus with diabetic nephropathy
E11.21	Type 2 diabetes mellitus with diabetic nephropathy

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Diabetes is present in 10% of the U.S. population. DN occurs in approximately 40% of patients who have diabetes for more than 10 yr.

PREVALENCE: DN develops in approximately 30% of patients with type 1 diabetes mellitus (T1DM) and 40% of patients with type 2 diabetes mellitus (T2DM) and is the leading cause of chronic kidney disease (CKD) and end stage renal disease (ESRD) worldwide. Among U.S. ESRD patients, 50% have DN as the primary cause for ESRD.

PREDOMINANT SEX AND AGE: Male patients and older age

GENETICS: Polygenetic. Patients with first-degree relative with DN are at increase risk.

RISK FACTORS:

- Male
- Older age
- Race: People of African descent, American Indian, Hispanic, Asian/Pacific Islander
- Family history of diabetic nephropathy
- Hyperglycemia
- Hypertension
- Obesity
- Diabetic retinopathy (DR)
- Smoking
- Hyperlipidemia

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Peripheral edema
- Foamy urine
- Weight gain or weight loss
- Hypertension
- Diabetic retinopathy
- Microalbuminuria/Proteinuria
- Decline in glomerular filtration rate (GFR)

ETIOLOGY

- DN develops as a result of microvascular complications associated with long-standing DM.
- DN is characterized by histologic changes (Fig. E1) including glomerular basement membrane thickening, mesangial matrix expansion, foot process effacement, arteriolar hyalinosis, microaneurysms, nodular glomerulosclerosis (Kimmelstiel-Wilson nodules) and tubulointerstitial fibrosis. These changes lead to urine albumin/protein excretion and decreased GFR.
- The pathophysiology leading to DN (Fig. 2) includes the generation of advance glycation end products, elaboration of growth factors, hemodynamic changes, and hormonal changes resulting in the release of reactive oxygen species and inflammatory mediators such as TNF-A, IL-1, and IL-6. These changes lead to glomerular hyperfiltration, glomerular hypertension, renal hypertrophy, and altered glomerular composition, which manifest as albuminuria, HTN, and progressive decline in renal function.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypertensive nephrosclerosis
- Focal segmental glomerulosclerosis
- Amyloidosis and light chain deposition disease
- IgA nephropathy
- Membranous nephropathy

WORKUP

- Workup should include thorough history and physical with focus on duration of DM, degree of hyperglycemia, and presence of complications (including DR) as well as appropriate laboratory testing (Fig. 3).

LABORATORY TESTS

- Urine albumin:creatinine ratio
  1. Microalbuminuria is defined as 30 to 299 mg/g and macroalbuminuria is defined as >300 mg/g
  2. Screening should be performed annually in patients with T1DM with >5-yr duration and annually for T2DM from its onset
  3. Confirm microalbuminuria with 2 to 3 elevated levels within a 3 to 6 mo period
  4. Early morning urine sample is recommended for identification of albuminuria. Prolonged standing, heavy exercise, UTI, and acute illness can cause transient albuminuria
  5. In T1DM microalbuminuria occurs 5 to 10 yr from onset
  6. In T2DM up to 25% of patients with DN may have little or no proteinuria
- GFR <60 ml/min/1.73 m^2
- Other tests
  1. Electrolytes
  2. Lipid profile

IMAGING STUDIES

- Renal ultrasound may help identify disease since kidney volume increases by an average of 15% with the onset of diabetes mellitus.
- Renal biopsy is confirmatory but is only reserved for patients with atypical features. Atypical features include rapid decline in GFR, overt proteinuria without prior microalbuminuria, active urine sediment, or features to suggest other systemic disease. In T2DM, DN can be present from the onset whereas in T1DM it typically develops after 5 yr. In general, patients with albuminuria, presence of DR, and lack of atypical features do not need renal biopsy (Fig. 4).

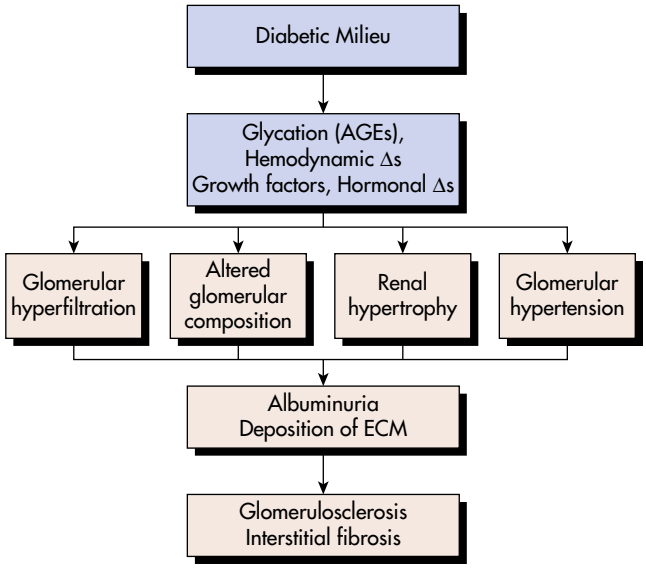

FIG. 2 Pathophysiology. *AGEs,* Advanced glycation end products; *ECM,* extracellular matrix. (From Umanath K et al: Update on diabetic nephropathy, *Am J Kidney Dis* 71:884, 2018.)

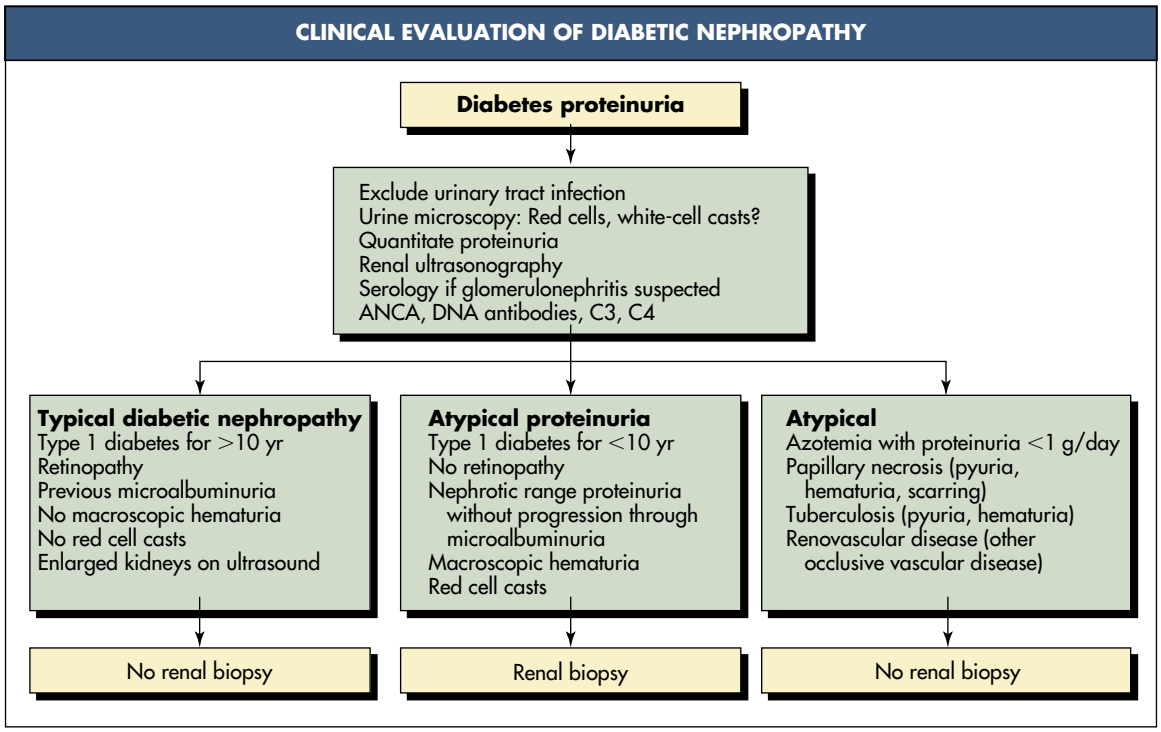

FIG. 3 Clinical evaluation of diabetic renal disease. *ANCA,* Anti-neutrophil cytoplasmic antibody. (From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, WB Saunders.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Smoking cessation
- Weight loss
- Dietary modifications—low carb, low fat, low potassium

ACUTE GENERAL Rx

- Early identification and an aggressive multiprong approach toward treatment of DN is of key importance to slow its progression (Table 1).
- Glycemic control with a goal A1C <7% is recommended as per KDOQI guidelines, with modification for patients at risk for hypoglycemia. Glycemic control delays microvascular complications and progression of DN.
- The ideal blood pressure goal is debatable. The current Kidney Disease Outcomes Quality Initiative (KDOQI) guideline recommends a goal BP <130/80; however, the Eighth Joint National Committee (JNC 8) guidelines recommend a goal BP <140/90.
- Use of renin-angiotensin-aldosterone system (RAAS) blockers should be the cornerstone of HTN management. ARB and ACE-I have been shown to reduce proteinuria, lower blood pressure, and slow the progression of DN. Combination therapy of ARB and ACE-I is not recommended due to risk of hyperkalemia and acute kidney injury.
- Lipid lowering therapy with an aim at cardiovascular risk reduction is recommended.

CHRONIC Rx

- Identify CKD anemia. Patients with DN are twice as likely to develop anemia compared to nondiabetic CKD and may need treatment with erythropoietin stimulating agents.
- Identify CKD bone-mineral metabolism disorder, especially adynamic bone disease, which develops more often with DN.
- Patients with DN should have timely referral for renal transplant and access evaluation as they progress to ESRD.
- Type IV renal tubular acidosis causing hyporeninemic hypoaldosteronism and hyperkalemia is common in DN, especially with the use of RAAS blockers and may require treatment with low potassium diet, diuretics, and/or potassium binders.

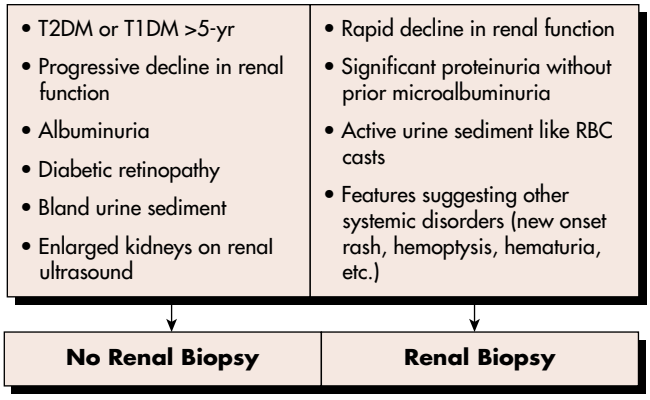

FIG. 4 Role of renal biopsy.

TABLE 1 Multiprong Approach Toward Diabetic Nephropathy

Glycemic control	Goal HbA_{1C} <7%
HTN control	Goal BP <130/80 mm Hg
RAAS blockers	ACE-I or ARB
Cardiovascular risk reduction	Smoking cessation and lipid management

ARB, Angiotensin receptor blocker; *ACE-I,* angiotensin-converting enzyme inhibitor; *BP,* blood pressure; *HbA_{1C},* glycosylated hemoglobin; *HTN,* hypertension; *RAAS,* renin-angiotensin-aldosterone system.

DISPOSITION

- Patients with DN with severe albuminuria and decreased GFR have poor prognosis and are at higher risk of cardiovascular events and deaths.
- The 5-yr survival rate of patients with diabetes and ESRD is approximately 30%.

REFERRAL

- Nephrology for CKD management
- Endocrinology for glycemic control
- Podiatry for foot care in the setting of neuropathy/peripheral vascular disease
- Ophthalmology for retinopathy management
- Dietician for specific dietary counseling

PEARLS & CONSIDERATIONS

- DN is the leading cause of CKD and ESRD worldwide. Early identification and an aggressive multiprong approach toward treatment of DN are key to slow its progression. Timely referral for renal transplant and access evaluation as they progress to ESRD are essential.
- DN is characterized by specific histologic findings; however, the diagnosis usually is made without renal biopsy due to the presence of clinic indicators including long duration of disease (usually >10 yr) and presence of other complications of the disease (albuminuria, retinopathy).
- RAAS blockage is a vital component of DN treatment. After initiation of RAAS blockage, chemistry panel should be periodically monitored to identify hyperkalemia or AKI.
- Insulin and many oral diabetic mediations are metabolized and cleared by kidneys and need dose adjustment with decline in renal function. Metformin is contraindicated with GFR <30 ml/min/1.73 m^2 and should be limited to <1000 mg/day in patients with GFR <45 ml/min/1.73 m^2 due to its association with lactic acidosis.
- Sodium-glucose cotransporter 2 (SGLT2) inhibitors have been shown in recent trials to improve renal outcomes in patients with T2DM.
- Patients with DN are at risk for AKI and should be counselled to avoid nephrotoxins such as nonsteroidal antiinflammatory drugs (NSAIDs).

PREVENTION

Treatment of risk factors including blood pressure, blood sugars, and obesity.

Diabetic Polyneuropathy ALG

BASIC INFORMATION

DEFINITION

Diabetic polyneuropathy is a distal symmetric polyneuropathy (DSPN) characterized by numbness, tingling, pain, or weakness that affects the nerves in a stocking-and-glove pattern, beginning in the distal extremities. DSPN leads to substantial pain, morbidity, and impaired quality of life. A number of different classification schemes exist for diabetic neuropathy; a common one is outlined in Box 1.

SYNONYMS

Distal symmetric polyneuropathy (DSPN)
Diabetic peripheral neuropathy

ICD-10CM CODES

E11.40	Type 2 diabetes mellitus with neurological complications
E11.40	Type 2 diabetes mellitus with diabetic neuropathy, unspecified
E11.41	Type 2 diabetes mellitus with diabetic mononeuropathy
E11.42	Type 2 diabetes mellitus with diabetic polyneuropathy
E11.43	Type 2 diabetes mellitus with diabetic autonomic (poly)neuropathy
E11.44	Type 2 diabetes mellitus with diabetic amyotrophy
E11.49	Type 2 diabetes mellitus with other diabetic neurological complication

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The prevalence of diabetic polyneuropathy varies from 10% to 100% in patients with diabetes mellitus in population-based studies. It is the most common form of peripheral neuropathy in the Western world.
RISK FACTORS: Patients with poor glycemic control, diabetic nephropathy, or retinopathy are at increased risk.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients most commonly experience numbness and tingling, but they may also experience either feelings of tightness or a sensation of heat or cold.
- Pain is common, is often worst at night, and can be burning, aching, shooting, or lancinating in nature.
- Sensory symptoms begin in the feet and may slowly ascend over months to years. Symptoms in the hands do not generally occur until symptoms in the lower extremities have reached the level of the knees. In more severe cases, the symptoms can spread to the trunk and head.
- Neurologic examination reveals early loss of small-fiber modalities resulting in decreased pinprick and temperature sensation and later involvement of large-fiber modalities leading to a reduction in vibratory and proprioceptive sensation. Ankle reflexes are usually reduced or absent, and more proximal reflexes may also become involved as the neuropathy progresses. Strength is usually normal, but there can be some motor involvement leading to mild weakness and atrophy, which is usually limited to intrinsic foot muscles and ankle dorsiflexors.

BOX 1 Clinical Classification of Diabetic Neuropathies

Symmetric
- Diabetic polyneuropathy
- Diabetic autonomic neuropathy
- Painful diabetic neuropathy

Asymmetric
- Diabetic radiculoplexopathy
- Diabetic thoracic radiculoneuropathy
- Mononeuropathies
- Carpal tunnel syndrome
- Ulnar neuropathy at the elbow
- Peroneal neuropathy at fibular head
- Cranial neuropathies

From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

ETIOLOGY

The precise etiology is unknown but most likely involves a complex interaction of metabolic derangements and microvascular insults occurring in the setting of diabetes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Although diabetes is the leading cause of peripheral neuropathy in developed countries, there are numerous other causes requiring further investigation(s).

WORKUP

- A thorough history and neurologic examination are essential to confirm features consistent with a diabetic polyneuropathy and exclude other features suggesting alternative diagnoses.
- For some patients, neuropathy may be the presenting feature of previously undiagnosed diabetes.
- Electrodiagnostic evaluation to include nerve conduction studies and electromyography can be helpful in confirming the presence, extent, and severity of a neuropathy.
- Patients with DSPN typically have a reduction of amplitudes and slowing of conduction velocities involving sensory and possibly motor nerves in a length-dependent and symmetric fashion.
- Electromyographic examination of distal muscles may reveal fibrillation potentials, positive sharp waves, and large motor unit action potentials, all suggestive of denervation and reinnervation.
- Electrodiagnostic testing may be negative if the neuropathy is limited to small fiber involvement.
- Neither skin biopsy nor nerve biopsy is necessary in the vast majority of cases.
- Fig. 1 describes a diagnosis and treatment algorithm of diabetic autonomic neuropathy.

LABORATORY TESTS

- Fasting blood sugar, hemoglobin A1c, and 2-hour oral glucose tolerance tests should all be considered in patients with peripheral neuropathy without a known history of diabetes.
- A focused laboratory evaluation for other common or potentially treatable causes of neuropathy is also indicated: Complete blood cell count, comprehensive metabolic panel to include electrolytes and liver function tests, vitamin B_{12} and folate levels, thyroid function tests, serum protein electrophoresis with immunofixation.
- Additional laboratory tests can be considered, based on either history or exam findings suggesting other underlying diagnoses, such as antinuclear antibodies, extractable nuclear antigens, ANCAs, rheumatoid factor, HIV, hepatitis B and C, and cryoglobulins.

IMAGING STUDIES

Imaging is not necessary unless there is concern for an alternate or coexisting process based on the history and examination.

TREATMENT

CHRONIC Rx

- Table 1 summarizes clinical features, diagnosis, and treatment of diabetic autonomic neuropathy.
- Glycemic control: The primary treatment for diabetic polyneuropathy is effective glycemic control, as this may either improve or at least slow progression of the neuropathy.
- Symptomatic management: Another aspect of treatment is the symptomatic management of pain and paresthesias. The American Academy of Neurology, the American Association of Neuromuscular and Electrodiagnostic Medicine, and the American Academy of Physical Medicine and Rehabilitation have together developed an evidence-based guideline for the treatment of painful diabetic neuropathy. Pregabalin, an anticonvulsant, is the only agent in the guideline that has been established as effective for painful diabetic neuropathy. Other probably effective agents are listed in the following:
  1. Topical agents: Lidocaine 5% patch can be applied to painful areas for 12 hours a day, capsaicin 0.075% applied qid.
  2. Anticonvulsants: Gabapentin (100 to 1200 mg tid), pregabalin (50 to 100 mg tid), carbamazepine (100 mg bid).
  3. Antidepressants: Amitriptyline (10 to 100 mg qhs), nortriptyline (25 to 150 mg qhs), duloxetine (60 to 120 mg daily).
  4. Tramadol (50 mg qid as needed) can be a useful adjunctive analgesic.
- Fig. 2 describes a treatment algorithm for neuropathic pain after exclusion of nondiabetic etiologies and stabilization of glycemic control.

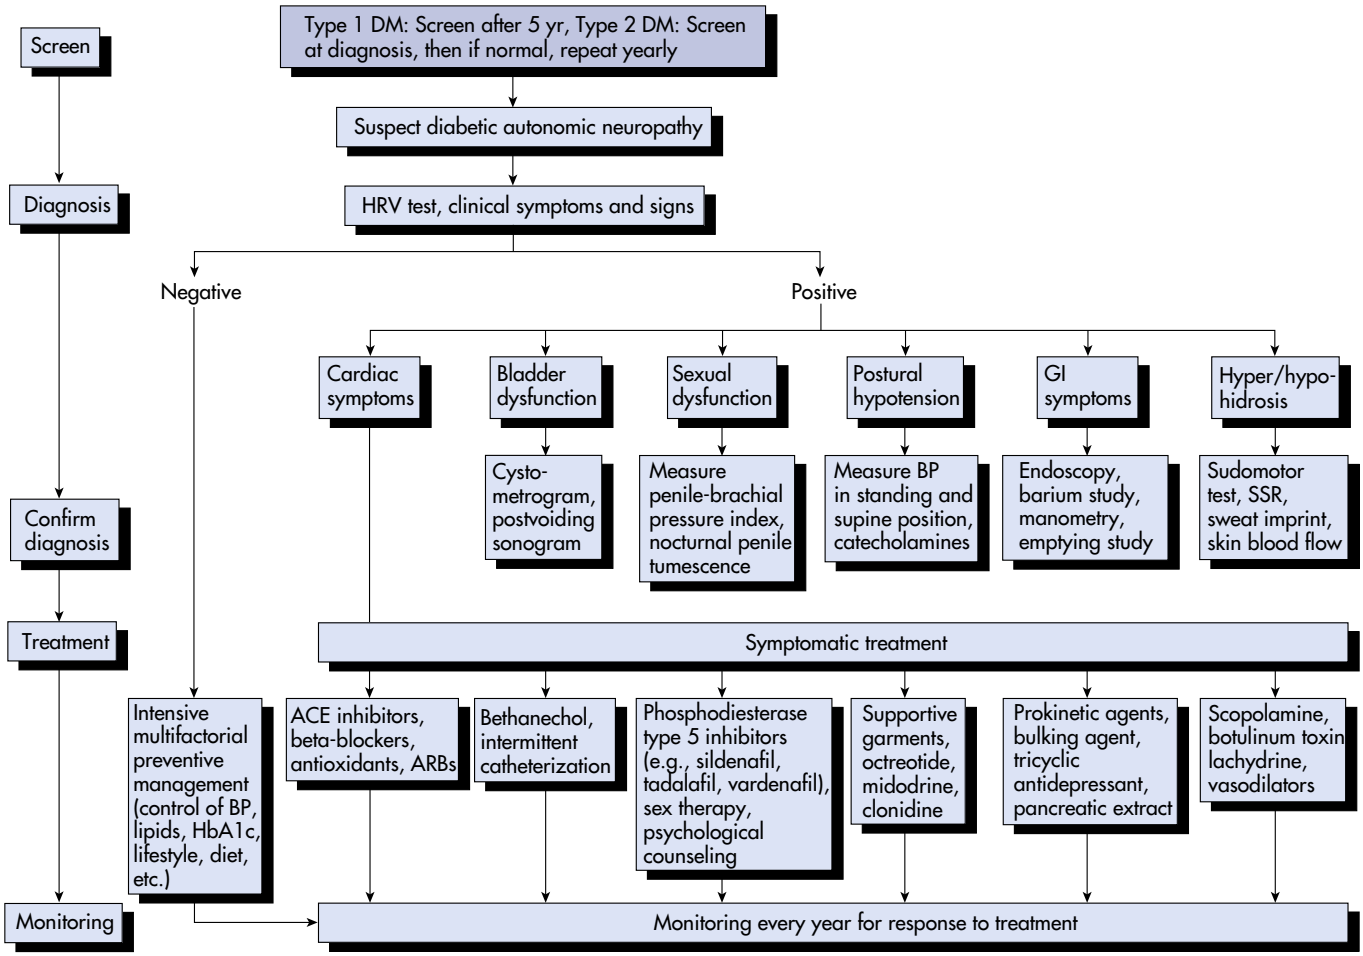

FIG. 1 Diagnosis and treatment algorithm of diabetic autonomic neuropathy. *ACE*, Angiotensin-converting enzyme; *ARBs*, angiotensin receptor blockers; *BP*, blood pressure; *DM*, diabetes mellitus; *GI*, gastrointestinal; *HbA1c*, glycohemoglobin; *HRV*, heart rate variability; *SSR*, sympathetic skin response. (Modified from Larsen PR et al [eds]: *Williams textbook of endocrinology*, ed 11, Philadelphia, 2008, WB Saunders.)

DISPOSITION

The distal sensory loss of diabetic polyneuropathy places patients at increased risk of trauma to the extremities, with the potential for ulceration and infection that could ultimately require amputation if not attended to in a timely fashion.

REFERRAL

- A neurologist can assist in the diagnosis and management of diabetic polyneuropathy.
- Patients with diabetic polyneuropathy should also be evaluated at least annually by a podiatrist and ophthalmologist.
- Progression of diabetic polyneuropathy can be minimized by paying close attention to strict glycemic control as well as other risk factors such as hypertension and obesity.

PEARLS & CONSIDERATIONS

COMMENTS

- For many patients, either DSPN or another form of diabetic neuropathy may be the initial presentation of previously undiagnosed diabetes.
- In addition to regular visits with podiatry, patients with diabetic polyneuropathy should be educated on aggressive foot hygiene and the importance of examining their own feet.

BASIC INFORMATION

DEFINITION

Diabetic retinopathy (Fig. 1) is a microvascular abnormality of the retina resulting in microaneurysms (Fig. E2), retinal hemorrhages, lipid exudates (Fig. E3), macular edema, and neovascular vessel growth (Fig. E4) and can ultimately end in blindness. Diabetic retinopathy can be classified into two stages: Nonproliferative (mild, moderate, and severe) and proliferative.

SYNONYMS

Nonproliferative diabetic retinopathy (NPDR)
Proliferative diabetic retinopathy (PDR)
Diabetic macular edema (DME)

ICD-10CM CODES

E08.311	Diabetes mellitus due to underlying condition with unspecified diabetic retinopathy with macular edema
E08.319	Diabetes mellitus due to underlying condition with unspecified diabetic retinopathy without macular edema
E08.321	Diabetes mellitus due to underlying condition with mild nonproliferative diabetic retinopathy with macular edema
E08.329	Diabetes mellitus due to underlying condition with mild nonproliferative diabetic retinopathy without macular edema
E08.331	Diabetes mellitus due to underlying condition with moderate nonproliferative diabetic retinopathy with macular edema
E08.339	Diabetes mellitus due to underlying condition with moderate nonproliferative diabetic retinopathy without macular edema
E08.341	Diabetes mellitus due to underlying condition with severe nonproliferative diabetic retinopathy with macular edema
E08.349	Diabetes mellitus due to underlying condition with severe nonproliferative diabetic retinopathy without macular edema
E08.351	Diabetes mellitus due to underlying condition with proliferative diabetic retinopathy with macular edema
E08.359	Diabetes mellitus due to underlying condition with proliferative diabetic retinopathy without macular edema

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- After 20 yr of diabetes mellitus, nearly 99% of patients with type 1 and 60% with type 2 disease demonstrate some degree of diabetic retinopathy.
- A leading preventable cause of blindness in the U.S. between the ages of 20 and 74 yr.
- There are approximately 8000 new cases of diabetic retinopathy–induced blindness each yr in the U.S.

PREVALENCE (IN U.S.):

- Prevalence of retinopathy increases with duration of diabetes. Found in 18% of people diagnosed with diabetes for 3- to 4-yr duration and in up to 80% of diabetics with a diagnosis of ≥15 yr.
- In the U.S., the prevalence of diabetic macular edema (the most common cause of vision impairment) is 4%, or approximately 750,000 people.
- CDC data reveal that 4 million Americans were visually impaired due to diabetic retinopathy in 2011.
- The number of Americans with diabetic retinopathy is expected to nearly double, from 7.7 million to 14.6 million between 2010 and 2050. Expected to triple in the Hispanic population.

PREDOMINANT SEX: Males and females affected equally

PREDOMINANT AGE: ≥30 yr

GENETICS:

- The development of diabetes involves the interaction of genetic and nongenetic factors.
- Type 1 has an autoimmune basis, resulting in destruction of beta islet cells and has strong HLA associations.
- Type 2 has genetic predisposition, but the specific genes are not yet well characterized.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Microaneurysms
- Hemorrhages
- Cotton-wool spots
- Lipid exudates
- Macular edema
- Neovascularization
- Retinal detachment (in advanced cases)
- Vitreous hemorrhage
- In early cases, patient may not report a visual disturbance

ETIOLOGY

Prolonged hyperglycemia results in basement membrane thickening in retinal capillaries with subsequent loss of pericytes and endothelial

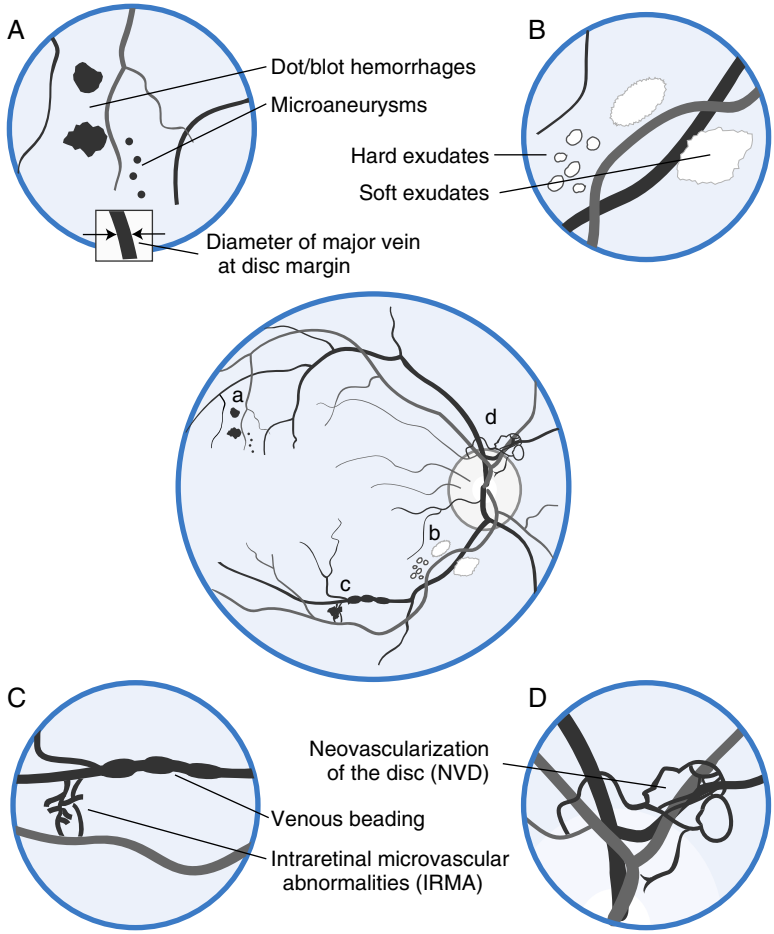

FIG. 1 Types of diabetic retinopathy. The center figure depicting the fundus of a patient with diabetic retinopathy is surrounded by four enlarged views, each labeled with a letter (a to d) corresponding to specific locations on the center figure. **A,** Microaneurysms and dot and blot hemorrhages. The diameter of microaneurysms is less than the width of a major vein at the disc margin (reproduced in square inset). **B,** Hard and soft exudates. **C,** Venous beading and intraretinal microvascular abnormalities (IRMA). **D,** Neovascularization, which may be located within one disc diameter of the optic disc (NVD) or elsewhere (NVE). Although both IRMA and neovascularization represent the formation of new blood vessels, IRMA are confined to the layers of the retina, whereas neovascularization is on the inner surface of the retina or vitreous. (From McGee S: *Evidence-based physical diagnosis*, ed 4, Philadelphia, 2018, Elsevier.)

decompensation resulting in breakdown of the blood–retina barrier and capillary occlusion, ischemia, and serum leakage. This leads to the clinical findings of dot hemorrhages, microaneurysms, lipid exudate, and edema. Upregulation of vascular endothelial growth factor (VEGF) and other cytokines contributes to vascular incompetence and promotes growth of neovascular tissue.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Branch or central retinal vein occlusion
- Hypertensive retinopathy
- Ocular ischemic syndrome (carotid occlusion)
- Radiation retinopathy
- Retinal macroaneurysm
- Sickle cell retinopathy
- Valsalva retinopathy
- Lupus
- Retinal vasculitis
- Terson syndrome

WORKUP

- Fundus photography
- Optical coherence tomography
- Optical coherence angiography
- Fluorescein angiogram
- Laboratory workup if indicated based on DDx

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Tight glycemic control remains the cornerstone in the primary prevention of diabetic retinopathy, particularly in type 1 as seen in the Diabetes Control and Complications Trial (DCCT) and less so in type 2 as seen in the United Kingdom Prospective Diabetes Study (UKPDS) and more recently in the Action to Control Cardiovascular Risk in Diabetes Trial (ACCORD). ADA guidelines recommend A1c <7.0.
- Intensive lowering of blood pressure was shown in UKPDS but not ACCORD to reduce progression of diabetic retinopathy. ADA guidelines recommend BP target of <140/90 mm Hg.
- Lipid lowering results in reduction of retinopathy progression (ACCORD Trial).
- Laser treatment (photocoagulation) for proliferative disease or noncenter involving macular edema.
- Table 1 summarizes classification and management of diabetic retinopathy.

ACUTE GENERAL Rx

- Intravitreal pharmacotherapy with anti-VEGF agents (e.g., bevacizumab, ranibizumab, aflibercept) and/or corticosteroids is the standard of care for patients with center-involved diabetic macular edema.
- Laser therapy: Panretinal laser photocoagulation reduces the risk of severe visual loss in patients with proliferative retinopathy.
- Focal laser reduces risk of moderate visual loss by 50% in patients with clinically significant macular edema.

TABLE 1 Abbreviated Early Treatment Diabetic Retinopathy Study (ETDRS) Classification of Diabetic Retinopathy

Category/Description	Management
Nonproliferative diabetic retinopathy (NPDR)	
No DR	Review in 12 mo
Very mild NPDR Microaneurysms only	Review most patients in 12 mo
Mild NPDR Any or all of: Microaneurysms, retinal hemorrhages, exudates, cotton wool spots, up to the level of moderate NPDR. No intraretinal microvascular anomalies (IRMA) or significant beading	Review range 6-12 mo, depending on severity of signs, stability, systemic factors, and patient's personal circumstances
Moderate NPDR • Severe retinal hemorrhages (more than ETDRS standard photograph 2A: About 20 medium to large per quadrant) in 1-3 quadrants or mild IRMA • Significant venous beading can be present in no more than 1 quadrant • Cotton wool spots commonly present	Review in approximately 6 mo Proliferative diabetic retinopathy (PDR) in up to 26%, high-risk PDR in up to 8% within a yr
Severe NPDR The 4–2–1 rule; one or more of: • Severe hemorrhages in all 4 quadrants • Significant venous beading in 2 or more quadrants • Moderate IRMA in 1 or more quadrants	Review in 4 mo PDR in up to 50%, high-risk PDR in up to 15% within a yr
Very severe NPDR Two or more of the criteria for severe NPDR	Review in 2-3 mo High-risk PDR in up to 45% within a yr
Proliferative diabetic retinopathy (PDR)	
Mild–moderate PDR New vessels on the disc (NVD) or new vessels elsewhere (NVE), but extent insufficient to meet the high-risk criteria	Treatment considered according to severity of signs, stability, systemic factors, and patient's personal circumstances such as reliability of attendance for review. If not treated, review in up to 2 mo
High-risk PDR • New vessels on the disc (NVD) greater than ETDRS standard photograph 10A (about ⅓ disc area) • Any NVD with vitreous hemorrhage • NVE greater than ½ disc area with vitreous hemorrhage	Treatment advised (see text) Should be performed immediately when possible, and certainly same day if symptomatic presentation with good retinal view

DR, Diabetic retinopathy.
From Bowling B: *Kanski's clinical ophthalmology, a systematic approach,* ed 8, Philadelphia, 2016, Elsevier.

- Vitrectomy for traction retinal detachment or vitreous hemorrhage.

CHRONIC Rx

- Monthly anti-VEGF injections until macular edema has resolved with surveillance at regular intervals for additional treatment
- Both ranibizumab (Lucentis) and aflibercept (Eylea) have been FDA-approved for treatment of diabetic retinopathy in patients with macular edema
- Repeated laser treatments may be necessary
- Diet and exercise; good medical control of disease, blood pressure, and cholesterol

DISPOSITION

- Retinal examination should be performed on all routine medical visits. Referral if abnormality seen.
- Routine annual eye examination in all patients with diabetes.
- Prognosis is improved with early diagnosis and treatment.

REFERRAL

Refer to ophthalmologist immediately on finding retinal abnormality to institute early treatment.

! PEARLS & CONSIDERATIONS

COMMENTS

- Early treatment of severe nonproliferative and proliferative retinopathy may minimize complications and visual loss.
- Tight blood sugar control in type 1 patients significantly reduces the probability of developing new-onset retinopathy as well as progression of existing retinopathy.
- Retinopathy is an independent risk marker for cardiovascular disease in patients with type 2 DM.

BASIC INFORMATION

DEFINITION

Persistent diarrhea is generally defined as an increase in stool frequency (>3 per day) or loose stool consistency for ≥4 wk. Some clinicians define persistent diarrhea as diarrhea lasting ≥14 days.

SYNONYM

Chronic diarrhea

ICD-10CM CODES	
R19.7	Diarrhea, unspecified
K52.9	Noninfective gastroenteritis and colitis, unspecified
K58.0	Irritable bowel syndrome with diarrhea
K59.1	Functional diarrhea
K90.9	Intestinal malabsorption, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Chronic diarrhea affects approximately 3% to 5% of the U.S. population.
- According to the World Health Organization, the prevalence of chronic diarrhea in children worldwide ranges from 3% to 20%.

PREDOMINANT SEX & AGE: Dependent on etiology:

- Irritable bowel syndrome (IBS) has a female/male ratio of 2:1, with peak prevalence from 20 to 39 yr of age.
- Celiac disease has a slight female predominance, and incidence is highest during infancy, in the third decade, and in the seventh decade.
- Crohn disease has bimodal incidence with peaks in the third and fifth decades.
- Ulcerative colitis has bimodal incidence first between ages 15 and 40 yr and then between ages 50 and 80 yr.
- Lactose intolerance incidence generally increases with age.
- Microscopic colitis is most common in middle-aged women.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

History:

- Specific symptoms: Loose stools, frequent stools, or urgency
- Fecal incontinence: Present or absent
- Duration
- Onset: Congenital, abrupt (infectious, idiopathic secretory diarrhea), or gradual
- Stool characteristics: Watery, bloody, fatty, malodorous
- Stool volume (watery, voluminous stool suggests disorder of small bowel or proximal colon. Frequent small stools suggest a disorder of left colon or rectum.)
- Abdominal pain: Location, relation to meals or bowel movements (inflammatory bowel disease [IBD], IBS, ischemia)
- Weight loss or fever (malabsorption, malignancy, IBD)
- Medical history: Immunologic, endocrine, neoplastic, human immunodeficiency virus (HIV), diabetes, surgery, radiation
- Surgical history: Any prior GI surgeries
- Travel history: Countries with bacterial and parasitic infectious sources
- Medications: All medications and supplements, especially focusing on new medications, drugs containing magnesium, any antibiotics in the past 6 to 8 wk; Box 1 summarizes medications and toxins associated with diarrhea
- Dietary history: Recent changes, "sugar-free" foods, fiber intake, raw seafood or shellfish, raw milk, impure drinking water, alcohol, associated of symptoms with specific food ingestion
- Family history: Absorptive defects (lactose intolerance), IBD, celiac disease, IBS, cancer
- Social history: Risk factors for HIV, receptive anal intercourse (infection or proctitis)
- Aggravating and alleviating factors: Relation to meals, diet, stress
- Excessive flatus, bloating (carbohydrate malabsorption)
- Nocturnal diarrhea (suggests secretory diarrhea)
- Symptoms suggesting IBS: Abdominal pain associated with altered bowel habits and improvement with defecation; often also associated with stress and depression with onset and severity of diarrhea

Physical:

- General: Fluid balance, nutrition (dehydration, malnutrition)
- Skin: Flushing (carcinoid syndrome), dermatitis herpetiformis (celiac disease)
- Mouth: Ulcers (Crohn disease)
- Neck: Thyroid mass or nodule (hyperthyroidism, multiple endocrine neoplasia), lymphadenopathy (malignancy or chronic infection)
- Abdomen
  1. Hepatomegaly (endocrine tumor, amyloidosis)
  2. Scars (surgical causes of diarrhea)
  3. Tenderness (inflammation)
  4. Mass, ascites, tenderness (multiple)
- Rectal:
  1. Sphincter weakness (fecal incontinence), anal fistula, fecal impaction

ETIOLOGY

Cause-specific etiology: Secretory, osmotic, steatorrheal, inflammatory, dysmotile, factitial, iatrogenic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

(See Box E2)

- Steatorrheal (fatty) diarrhea
  1. Malabsorption syndromes
     a. Mesenteric ischemia
     b. Mucosal diseases (e.g., celiac disease, Whipple disease)
     c. Small intestinal bacterial overgrowth (SIBO)
     d. Drug-induced enteropathy
  2. Maldigestion
     a. Inadequate luminal bile acid
     b. Pancreatic exocrine insufficiency
     c. Liver disease
     d. Bariatric surgery
- Inflammatory diarrhea (Table 1)
  1. Diverticulitis
  2. IBD (Crohn disease, ulcerative colitis, microscopic colitis)
  3. Infectious diseases
     a. Bacterial (e.g., tuberculosis, yersiniosis)
     b. Parasitic (e.g., amebiasis, strongyloidiasis)
     c. Pseudomembranous colitis (*C. difficile*)
     d. Ulcerating viral (e.g., cytomegalovirus, herpes simplex virus)
  4. Ischemic colitis
  5. Neoplasia (colon cancer, lymphoma)
  6. Radiation colitis
- Watery diarrhea (Table 2)
  1. Osmotic diarrhea
     a. Carbohydrate malabsorption (e.g., lactose intolerance)
     b. Osmotic laxatives (e.g., magnesium, phosphate, sulfate, sorbitol)
     c. Gluten and FODMAP intolerance

BOX 1 Medications and Toxins Associated with Diarrhea

Acid-reducing agents (e.g., H_2RAs, PPIs)
Antacids (e.g., those that contain magnesium)
Antiarrhythmics (e.g., quinidine)
Antibiotics (most)
Anti-inflammatory agents (e.g., 5-aminosalicylates, gold salts, NSAIDs)
Antihypertensives (e.g., β-adrenergic receptor blocking drugs)
Antineoplastic agents (many)
Antiretroviral agents
Colchicine
Heavy metals
Herbal products
Prostaglandin analogs (e.g., misoprostol)
Theophylline
Vitamin and mineral supplements

H_2RA, Histamine-2 receptor agonist; *NSAID,* nonsteroidal anti-inflammatory drug; *PPI,* proton pump inhibitor.

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE 1 Clinical Findings that Suggest the Causative Organisms for Some Inflammatory Diarrheas

Finding	Causative Organisms
Hemolytic-uremic syndrome/thrombotic thrombocytopenic purpura	Shiga toxin-producing *Escherichia coli*; most common with *Shigella dysenteriae* among *Shigella* spp., but *S. dysenteriae* is not found in the U.S.
Reactive arthritis*	*Salmonella* spp., *Shigella* spp., *Campylobacter* spp., *Yersinia* spp.
Bone-marrow suppression	*Salmonella* serovars Typhi and Paratyphi
Guillain-Barré syndrome	*Campylobacter jejuni*
Toxic megacolon	*Shigella* spp., *Clostridium difficile, Salmonella* (rarely)
Aortitis/endovascular infection	Nontyphoidal *Salmonellae*
Intestinal hemorrhage/perforation	*Salmonella* serovars Typhi and Paratyphi, TB enteritis
Right lower quadrant tenderness	*Yersinia* spp.
Cellulitis	*Vibrio vulnificus* and *alginolyticus* (see text)
Postinfection IBS	All, including viral gastroenteritis; viruses typically yield less severe postinfection IBS
Small-bowel lymphoproliferative disease	*Campylobacter jejuni*

*Can occur with any enteric pathogen.
IBS, Inflammatory bowel syndrome.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

2. Secretory diarrhea
   a. Bacterial toxins
   b. Congenital syndromes (e.g., congenital chloridorrhea)
   c. Disordered motility
      (1) Diabetic neuropathy
      (2) IBS
      (3) Postsympathectomy
      (4) Postvagotomy
      (5) Diabetic neuropathy
   d. Endocrinopathies
      (1) Addison disease
      (2) Carcinoid syndrome
      (3) Gastrinoma
      (4) Hyperthyroidism
      (5) Mastocytosis
      (6) Medullary carcinoma of the thyroid
      (7) Pheochromocytoma
      (8) Somatostatinoma
      (9) VIPoma
   e. Idiopathic secretory diarrhea
   f. Ileal bile acid malabsorption
   g. IBD (Crohn disease, ulcerative colitis, microscopic colitis [collagenous])
   h. Laxative abuse
   i. Medications and toxins
   j. Lymphocytic colitis
   k. Neoplasia (colon carcinoma, lymphoma, villous adenoma in rectum)
   l. Vasculitis
3. Factitial causes
   a. Munchausen
   b. Eating disorders
4. Iatrogenic causes
   a. Cholecystectomy
   b. Ileal resection
   c. Bariatric surgery

WORKUP

- Due to the many potential causes of chronic diarrhea, it is impractical to use the same diagnostic tests on every patient.
- Good history and physical examination should be obtained (as mentioned previously), and the workup should be tailored accordingly.
- First determine the type of diarrhea (watery, fatty, or inflammatory) based on the history and physical examination. Further tests may then be obtained to differentiate the diseases in that subtype of diarrhea.
- Basic laboratory testing may include complete blood count (CBC) (anemia, leukocytosis), electrolyte tests, liver function tests, albumin, erythrocyte sedimentation rate, C-reactive protein, and thyroid stimulating hormone.
- Initial stool studies may include fecal leukocyte and fecal occult blood testing.
- Further lab testing as indicated by clinical suspicion:
  1. IBD: Fecal calprotectin
  2. Diarrhea after hospitalization or recent antibiotics: *Clostridium difficile* stool toxin
  3. Suspected laxative abuse: Stool laxative screen
  4. Malabsorption: Fecal fat, Sudan stain
  5. Celiac panel (tissue transglutaminase immunoglobulin A), especially in patients with iron deficiency anemia on CBC
  6. Watery diarrhea
     a. Fecal osmotic gap: 290 – 2([Na^+] – [K^+])
        (1) Gap >125 mOsm/kg suggests osmotic diarrhea.
        (2) Gap <50 mOsm/kg suggests secretory diarrhea.
     b. Fecal pH
        (1) pH <5.3 suggests carbohydrate malabsorption (lactose intolerance).

Rx TREATMENT

In most cases, an underlying etiology should be discovered and treated accordingly. However, nonspecific treatment may be used in several situations:

- Volume depletion that requires treatment (or hospitalization) during evaluation.
- Specific treatment for a condition fails to adequately treat diarrhea.
- No specific treatment is available.

NONPHARMACOLOGIC THERAPY

- If etiology can be managed with diet modification (e.g., lactose intolerance or celiac disease), offending substance should be eliminated from diet.
- Reasonable to have trial of reduced dietary lactose and caffeine and monitor for improvement.
- Fiber supplementation (psyllium) can thicken stool consistency; however, it may increase stool output.
- Patients with stool output greater than 1000 g per day often receive IV hydration, but as an alternative, most could be managed with oral rehydration solution (ORS).
- Other therapies would be determined by the specific etiology of persistent diarrhea.

CHRONIC Rx

- General principles:
  1. Opiates are the most effective nonspecific antidiarrheal drugs. In general, they should not be used in severe diarrhea due to acute infections, massive intestinal resection, or secretion of endogenous secretagogues.
  2. Less potent opiate agents (loperamide) should be attempted first, but treatment should be escalated to more potent agents if low-potency opiates fail.
  3. Avoid high-potency agents when concerns of narcotic abuse and/or dependence exist.
  4. When prescribed, opiates should be used on a scheduled basis rather than as needed.
- Low-potency opiate antidiarrheals
  1. Diphenoxylate with atropine (Lomotil) 2.5 to 5 mg 4× daily
  2. Loperamide (Imodium) 2 to 4 mg 4× daily
- More potent opiate antidiarrheals (avoid in alcoholics or history of drug abuse)
  1. Codeine 15 to 60 mg 4× daily
  2. Morphine 2 to 20 mg 4× daily
  3. Tincture of opium 2 to 20 drops 4× daily
- Alpha-2 agonist
  1. Clonidine 0.1 to 0.3 mg 3× daily.
  2. Utility limited by hypotensive effect. Opiate agents should be attempted first.
- Intraluminal agents
  1. Used to bind toxins and change stool consistency
  2. Usually ineffective as monotherapy in managing chronic diarrhea
  3. Fibers: Psyllium, calcium polycarbophil, methylcellulose
  4. Bismuth: Pepto-Bismol
  5. Clays: Attapulgite, kaolin
  6. Bile acid–binding resins: Cholestyramine, colestipol
- Newer agent
  1. Racecadotril, an antisecretory enkephalinase inhibitor
  2. Not yet available in the U.S.

TABLE 2 Secretory versus Osmotic Diarrhea

Type of Diarrhea	Causes	Examples
Secretory	Exogenous secretagogues	Enterotoxins (e.g., cholera)
	Endogenous secretagogues	Neuroendocrine tumors (e.g., carcinoid syndrome)
	Absence of ion transporter	Congenital chloridorrhea
	Loss of intestinal surface area	Intestinal resection, diffuse intestinal mucosal disease
	Intestinal ischemia	Diffuse mesenteric atherosclerosis
	Rapid intestinal transit	Intestinal hurry following vagotomy
Osmotic	Ingestion of poorly absorbed agent	Magnesium ingestion
	Reduced nutrient transport	Lactase deficiency

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

COMPLEMENTARY & ALTERNATIVE MEDICINE

There is growing evidence that shows some benefit of probiotics in the treatment of infectious diarrhea, IBS, *Clostridium difficile* disease, and antibiotic-associated diarrhea.

DISPOSITION

Etiology dependent

REFERRAL

Gastroenterology referral is warranted depending on severity of symptoms, need for endoscopic procedures, and/or need for long-term disease management.

PEARLS & CONSIDERATIONS

COMMENTS

- A good history is crucial in the evaluation of chronic diarrhea. An attempt should be made to classify diarrhea as watery, fatty, or inflammatory.
- Fecal incontinence is often described by patients as diarrhea, and many patients are reluctant to volunteer more information on this subject unless specifically asked.
- IBS is one of the most common causes of chronic diarrhea and requires minimal laboratory studies. Patients should be screened appropriately.
- An underlying etiology of chronic diarrhea should be determined and treated accordingly.

PATIENT & FAMILY EDUCATION

- Disease-specific education

Diffuse Idiopathic Skeletal Hyperostosis

BASIC INFORMATION

DEFINITION

Diffuse idiopathic skeletal hyperostosis (DISH) is a systemic disorder primarily involving the axial skeleton. DISH is characterized by widespread bone proliferation as well as calcification and ossification of soft tissues, including ligaments and their sites of insertion. DISH is known to be associated with certain metabolic abnormalities.

SYNONYMS

Ankylosing hyperostosis
Forestier disease
DISH

ICD-10CM CODES

M48.10	Ankylosing hyperostosis, site unspecified
M48.11	Ankylosing hyperostosis, occipito-atlanto-axial region
M48.12	Ankylosing hyperostosis, cervical region
M48.13	Ankylosing hyperostosis, cervico-thoracic region
M48.14	Ankylosing hyperostosis, thoracic region
M48.15	Ankylosing hyperostosis, thoraco-lumbar region
M48.16	Ankylosing hyperostosis, lumbar region
M48.17	Ankylosing hyperostosis, lumbosacral region
M48.18	Ankylosing hyperostosis, sacral and sacrococcygeal region
M48.19	Ankylosing hyperostosis, multiple sites in spine

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The prevalence of DISH varies in different populations. Factors such as age, ethnicity, geography, and clinical setting affect the prevalence of the disease. Studies have shown DISH is more common in developed nations, although this may be secondary to more frequent use of radiologic imaging in these countries. Higher prevalence rates are seen in men, 10% to 25% versus 5% to 15% in women over the age of 50 yr. Rates increase with age, with prevalence reported as high as 35% in men and 26% in women over the age of 70 yr.

PREDOMINANT SEX AND AGE:

- Male predominance with a ratio of 2:1
- Mostly seen in elderly patients, usually after the age of 50 yr

GENETICS: Association with *COL6A1* gene in some populations, causing ossification of the posterior longitudinal ligament, a condition related to DISH. Matrix Gla protein and Dickkopf-1 (inhibitors of bone formation) may be deficient in DISH patients, leading to hyperostosis.

RISK FACTORS:

- Obesity
- Type II diabetes mellitus
- Dyslipidemia
- Hypertension
- Hyperinsulinemia
- Elevated growth hormone and insulin-like growth factor (IGF-1) levels
- Chronic vitamin A toxicity/retinoid use

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients with DISH are usually asymptomatic or experience increased stiffness in the spine or peripheral joints. In the spine, osteophytes can obstruct or impinge on other structures or tissues, causing dysphagia (DISH affecting the cervical spine), myelopathy, quadriplegia, spinal stenosis, and ossification of posterior longitudinal ligament. Spinal ligament calcification and ossification leads to decreased range of motion and a stooped posture as well as an increasing risk for fractures. Peripheral enthesopathies are usually asymptomatic, but mechanical stresses can injure the entheses and cause pain. In patients with DISH, pronounced hypertrophic changes can be seen affecting certain peripheral joints that are not typically associated with OA, such as the metacarpophalangeal joints, elbows, shoulders, and ankles. Thoracic spinal involvement is common in DISH and not usually seen in OA. Patients with DISH are at increased risk for heterotopic ossification after orthopedic surgery (i.e., hip arthroplasty).

ETIOLOGY

Etiology of DISH is unknown and the cause of excess bone formation is unclear. Chondrocytes located in entheseal areas become activated and cause changes in the adjacent matrix leading to ossification (Fig. E1). Local vascular infiltration also promotes ossification.

DIAGNOSIS

Diagnosis of DISH is made by radiographic imaging. Bone formation is typically seen in the thoracic spine, and less frequently in the cervical and lumbar spines. Coarse osteophytes that seem to "flow" between adjacent vertebrae are seen on the right side of the thoracic spine (Fig. E2), thought to be subsequent to the pressure effect of the left-sided aorta. Ossification occurs within the overlying anterior longitudinal ligament (Fig. E3), preserving the original bone cortex. The intervertebral disc height is preserved in the involved segments. Peripheral bone formation is seen in entheseal areas, especially around the heels (Achilles tendon and plantar fascia), knees (peripatellar ligaments), and elbows (olecranon). Peripheral new bone formation can be seen as well, with increased distal finger tuft thickening, increased sesamoid bone size, and increased cortical bone thickness. There is no evidence of apophyseal joint ankylosis or sacroiliac involvement.

Resnick and Niwayama criteria: Most frequently used and is based on radiographic findings in the spine:

- Findings of new bone formation/osteophytes bridging four adjoining vertebral bodies or ossification of the anterolateral longitudinal ligament
- Preserved intervertebral disc height
- Absence of degenerative disc disease, sacroiliac joint, or facet joint involvement or changes

Others have proposed different criteria for diagnosis, which include the presence of peripheral enthesopathy. New diagnostic criteria

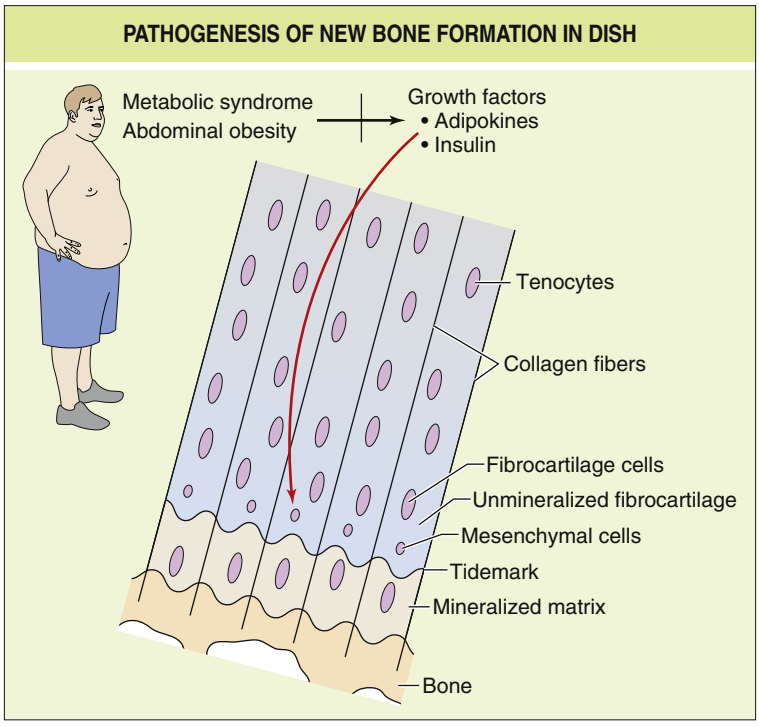

FIG. E1 Diagram of the enthesis showing cellular components that respond to growth factor stimulation, resulting in new bone formation that characterizes diffuse idiopathic skeletal hyperostosis (DISH). (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

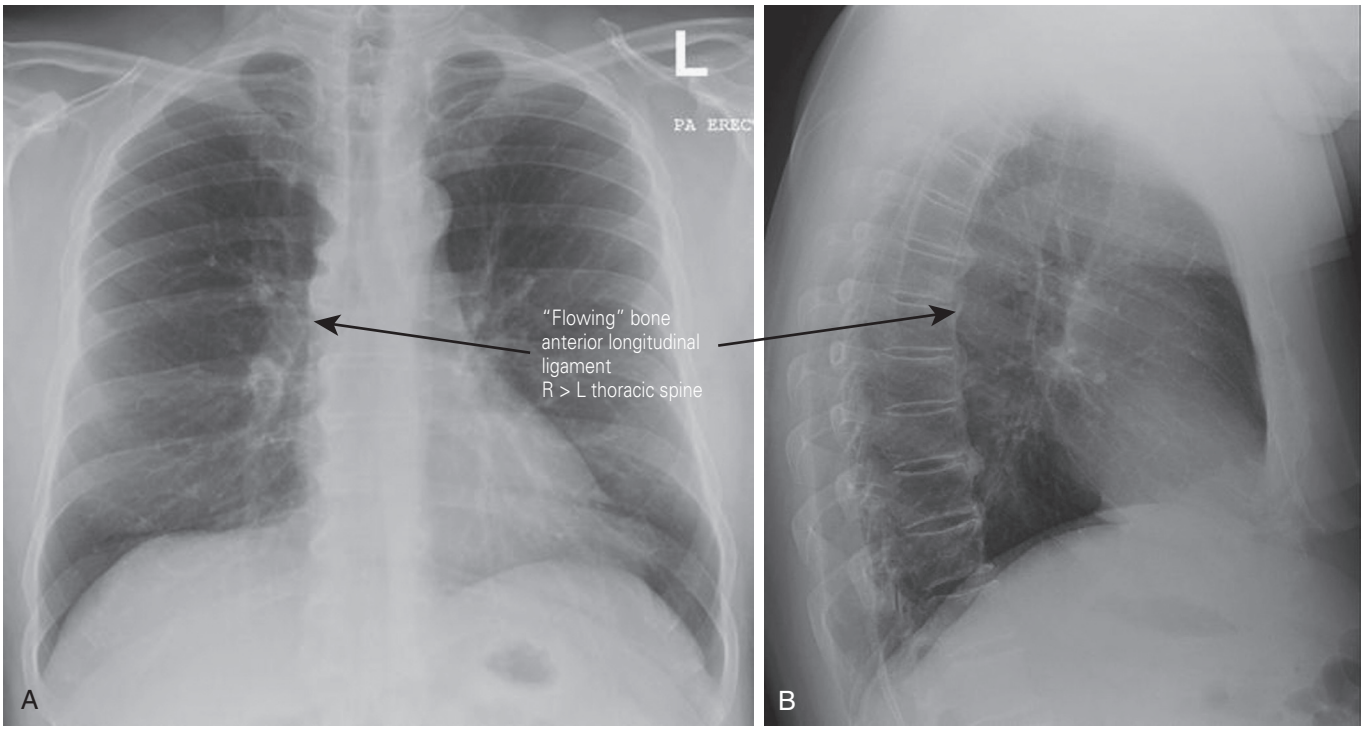

FIG. E2 Typical radiographic findings in the thoracic spine on routine chest radiographs (posteroanterior **[A]** and lateral **[B]**), with "flowing" new bone formation linking four contiguous vertebrae, predominantly right-sided, in absence of intervertebral disk change. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

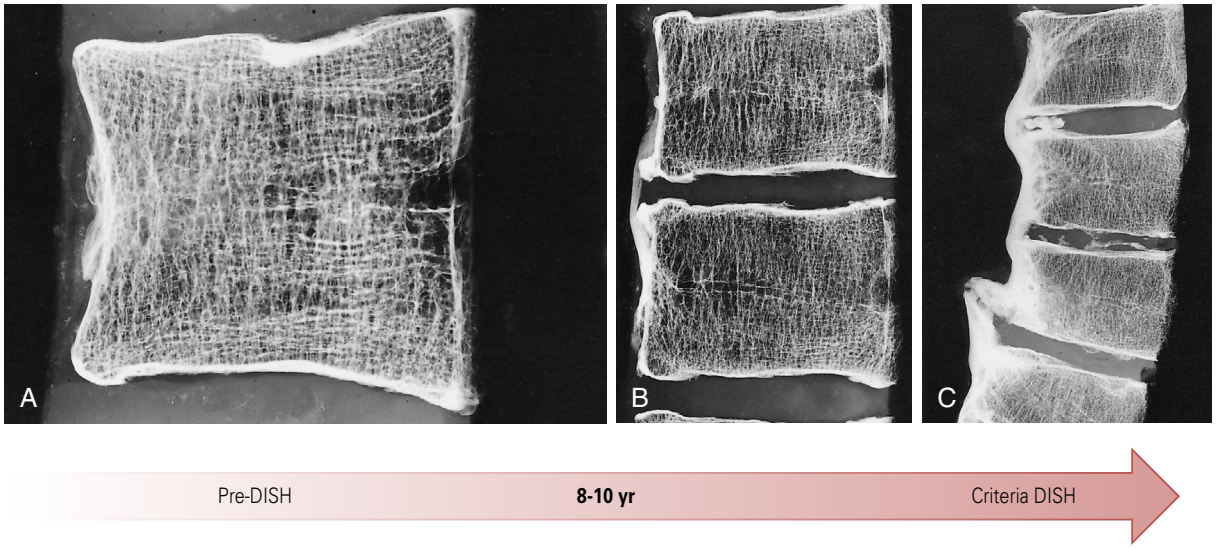

FIG. E3 Progressive spinal entheseal changes in diffuse idiopathic skeletal hyperostosis (DISH). (A) The earliest change is seen, with ossification at the site of attachment of the anterior longitudinal ligament to the middle of the vertebral body, well away from the annulus. Note the separation of the ossification from the intact cortex, except at the site of attachment. **(B)** Moderately advanced changes, with ossification bridging the disk space but still firmly attached to cortex at the middle of the vertebral body. **(C)** Advanced changes, typical of established DISH, with smooth attachment of the new bone to the original cortex. The ossified ligament is much thickened and interrupted at the lower level. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

are needed to help recognize milder forms of the disease, those affecting other parts of the spine, and those that manifest initially with peripheral enthesopathy.

DIFFERENTIAL DIAGNOSIS

- Ankylosing spondylitis (Table E1 describes selected differences)
- Degenerative disc disease—spondylosis deformans
- Acromegaly
- Ossification of the posterior longitudinal ligament

WORKUP

Diagnosis of DISH is made with radiologic imaging. Patients with the above risk factors (increased weight, BMI, waist circumference, and systolic blood pressure) are at risk for cardiovascular disease and evaluation for this also should be pursued.

LABORATORY TESTS

- Routine biochemical tests and erythrocyte sedimentation rate (ESR) are normal
- Laboratory testing should include evaluation for metabolic syndrome, i.e., fasting glucose or HgbA1c, cholesterol panel, etc.
- Uric acid

TABLE E1 Selected Differences between Diffuse Idiopathic Skeletal Hyperostosis and Axial Spondyloarthropathy

Disorder	Diffuse Idiopathic Skeletal Hyperostosis	Axial Spondyloarthropathy
Age at presentation	Usually older than 50 yr	Usually younger than 40 yr
Associated metabolic disorder	Usually present	Not necessarily present
HLA B27	No association	Strong association
Spinal new bone	Usually exuberant, with preservation of bony cortex; there may be a gap between new bone in anterior longitudinal ligament and vertebra	Usually narrow, vertically aligned new bone that is confluent with the underlying vertebra
Sacroiliac joints	Plain radiographs may show anterior osteophytosis, causing "bland fusion" without erosion or sclerosis. CT scan may show sacroiliac anterior joint-line fusion, without erosion or sclerosis. Bone scan and MRI are normal	Plain radiographs show variable joint irregularity caused by erosions, bridging new bone, and joint line sclerosis. CT scan shows variable sacroiliac joint irregularity, erosion, fusion, or sclerosis. In active inflammatory regions, bone scan shows increased uptake, and MRI shows bone marrow edema and synovitis
Entheseal regions	Usually large, well-corticated enthesophyte; sometimes radiologic gap at the entheseal attachment	Entheseal new bone usually smaller with less well-defined margins and irregular, fluffy new bone at distal entheseal area

CT, Computed tomography; *HLA,* human leukocyte antigen; *MRI,* magnetic resonance imaging.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

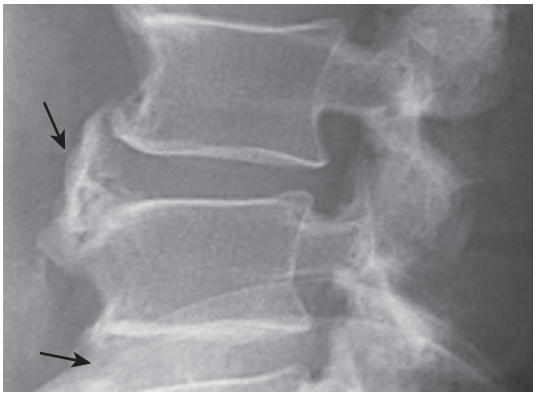

FIG. E4 Diffuse idiopathic skeletal hyperostosis (DISH): Lumbar spine. This lateral radiograph of the lumbar spine shows early changes of DISH. Calcifications of the anterior longitudinal spinal ligament *(arrows)* are evident and will eventually evolve into flowing osteophytes extending across multiple spinal levels. (From Firestein GS: *Kelley's textbook of rheumatology*, ed 9, Philadelphia, 2013, Saunders.)

IMAGING STUDIES

- Posteroanterior and lateral (Fig. E4) x-ray views of the spine
- Computed tomography (CT) or magnetic resonance imaging (MRI) of the spine (Fig. E5) (not routinely needed unless evaluating for other possible conditions such as spinal stenosis)
- Plain radiographs of symptomatic peripheral joints

Rx TREATMENT

There is no specific treatment available for DISH, and it is largely symptomatic. Management issues are summarized in Table E2.

- Weight management
- Treatment and control of components of metabolic syndrome
- Treat cardiovascular risk factors

NONPHARMACOLOGIC THERAPY

- Physical therapy, light exercise
- Heat
- For peripheral enthesopathy pain, local soft applications such as insoles for plantar spurs or orthotics can be used as well as protective bandages at other sites
- Surgical intervention rarely necessary, unless complications such as dysphagia from cervical osteophytes or spinal stenosis occurs

ACUTE GENERAL Rx

- Analgesics and nonsteroidal anti-inflammatory medications (NSAIDs)
- Local corticosteroid injections

CHRONIC Rx

- Pain management as above
- Prevention of heterotopic ossification after orthopedic surgical procedures: NSAIDs, anti-vitamin K, and irradiation

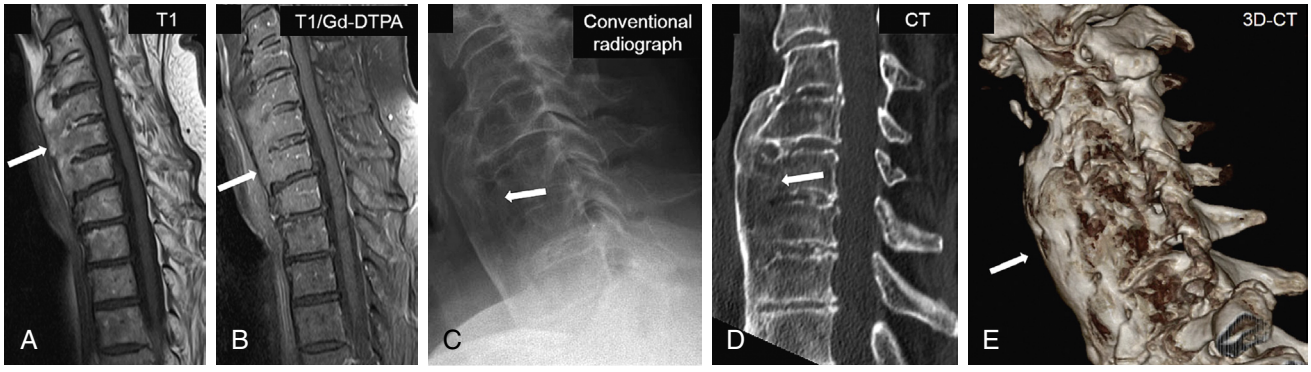

FIG. E5 Diffuse idiopathic skeletal hyperostosis (DISH) in the cervical spine, characterized by bulky osteophytes *(arrow),* which exceed the length of the anterior longitudinal ligament. (A) T1-weighted image. **(B)** T1/gadolinium diethylenetriamine–pentaacetic acid (T1/Gd-DTPA) image. **(C)** Conventional radiograph. **(D)** Computed tomography (CT) image. **(E)** Three-dimensional computed tomography (3D-CT) image. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

TABLE E2 Management Issues in Diffuse Idiopathic Skeletal Hyperostosis

Issue	Management
Spinal and Peripheral Enthesopathy	
Asymptomatic (usual)	Encourage exercise and ideal body weight; assess cardiovascular risk factors
Symptomatic	As above plus physical therapy, local corticosteroid injection therapy, and analgesic and anti-inflammatory agents
Complications	
Facet arthritis	Physical therapy, corticosteroid injection
Spinal stenosis	Exercise, corticosteroid injection, surgery
Dysphagia	Conservative (e.g., smaller meal servings), surgery
Osteoarthritis	Standard approaches
Associated Metabolic Syndrome	
Hypertension, diabetes, dyslipidemia, gout, obesity	Treat vigorously

From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

Digoxin Overdose

BASIC INFORMATION

DEFINITION

Digoxin, a cardiac glycoside, is used for the treatment of symptomatic heart failure with reduced ejection fraction and ventricular rate control in atrial fibrillation.

Chronic digoxin therapy or acute overdose can cause toxicity. Toxicity can occur even when serum levels are within the therapeutic range.

SYNONYMS

Digitalis overdose
Cardiac glycoside toxicity

ICD-10CM CODE

T46.0X1A Poisoning by cardiac-stimulant glycosides and drugs of similar action, accidental (unintentional), initial encounter

PHARMACOKINETICS

Steady-state levels (not peak levels) correlate with toxicity; digoxin reaches steady state in 5 to 7 days.
BIOAVAILABILITY: Approximately 80% tablets; 100% capsules or IV
VOLUME OF DISTRIBUTION: 5 to 7 L/kg, highly tissue bound
HALF-LIFE: 36 to 48 hr
EXCRETION: Predominantly renal
THERAPEUTIC LEVEL: 0.5 to 2 ng/ml (0.5 to 0.9 ng/ml suggested in heart failure and <1.2 for atrial fibrillation); check level 1 wk after starting therapy or changing dose. Sample should be drawn at least 6 hr after last dose.

EPIDEMIOLOGY & DEMOGRAPHICS

- Digoxin toxicity remains relatively common despite decline in digoxin use, likely because of its narrow therapeutic range. Occurs in up to 5% of individuals on therapy.
- Factors that potentiate toxicity (may increase level or modify cardiac sensitivity): Advanced age, female gender, renal insufficiency, cardiac or pulmonary disease, hypokalemia, hyperkalemia, hypomagnesemia, hypercalcemia, hypernatremia, acid-base disturbance, hypoxia, hypothyroidism, volume depletion, and drugs that affect elimination (ACE inhibitors, amiodarone, carvedilol, clarithromycin, cyclosporine, diltiazem, erythromycin, itraconazole, ketoconazole, NSAIDs, rifampin, spironolactone, tetracyclines, quinidine, verapamil, and herbal supplements), coingestion of cardiotoxic drugs (beta-blockers, calcium channel blockers, tricyclic antidepressants).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Cardiac, gastrointestinal, and central nervous systems are affected. Fatigue, malaise, and weakness are common symptoms. Presentation may differ in acute vs. chronic toxicity. Acute toxicity may be asymptomatic for several hours. Chronic toxicity is more difficult to recognize because of the nonspecific presentation; visual disturbance and mental status changes may be most prominent.

CARDIAC: Initial presentation often due to proarrhythmic effects; can present with almost any dysrhythmia or conduction block except rapidly conducted atrial arrhythmias. Premature ventricular complexes and bradycardia are common. Patients with healthy hearts usually present with bradyarrhythmias and AV block, and those with underlying heart disease often present with ventricular arrhythmias.
GASTROINTESTINAL: Anorexia, nausea, vomiting, diarrhea, abdominal pain
CENTRAL NERVOUS SYSTEM:

- Headache, dizziness, visual disturbance (flashing lights, halos, blurred vision, scotomas, change in color perception), lethargy, confusion, hallucinations, delirium, syncope.
- Hyperkalemia is usually seen in acute poisoning; hypokalemia is more common in chronic toxicity.

ETIOLOGY

Digoxin affects cardiac cells, the autonomic nervous system, and vascular smooth muscle. Digoxin reversibly inhibits the sodium-potassium ATPase pump (Na^+, K^+-ATPase) in myocardial cells, increasing extracellular K^+ and intracellular Na^+. This reduces the activity of the Na-Ca exchanger, leading to intracellular accumulation of calcium. This increases myocardial contractility and cardiac output, the positive inotropic effect associated with digoxin therapy. Cardiac glycosides also decrease the heart rate (effect on SA node) and slow conduction through the AV node by increasing vagal tone. Digoxin also has other neurohormonal and hemodynamic effects that are not completely understood. In toxicity, enhanced automaticity and excitability of cardiac tissue and depressed conduction facilitate extrasystoles and arrhythmias.

DIAGNOSIS

Digoxin toxicity is a clinical diagnosis; patients can have toxicity even when the digoxin level is within therapeutic range.

DIFFERENTIAL DIAGNOSIS

Toxicity due to other cardiac glycosides:

- Digitoxin
- Deslanoside
- Lanatoside C
- Ouabain

Side effects from other medications:

- Beta-blockers
- Calcium channel blockers
- Clonidine
- Cyclic antidepressants
- Encainide and flecainide
- Procainamide
- Propoxyphene
- Quinidine

Ingestion of plants producing digitalis-like glycosides:

- Foxglove
- Oleander
- Lily of the valley

Cardiac conduction abnormalities:

- Sick sinus syndrome
- AV node dysfunction

Electrolyte abnormalities:

- Hyperkalemia

WORKUP

- History: Change in medical condition, medication changes, herbal supplements, deliberate overdose. In acute toxicity, determine the amount and time of ingestion and possible coingestions.
- Physical examination.

LABORATORY TESTS

- Chronic toxicity—check stat digoxin level.
- Acute toxicity—check stat digoxin level and recheck 6 hr after ingestion (initial high levels may not be toxic, as tissue redistribution will occur).
- Potassium, BUN, creatinine, magnesium, calcium, glucose.
- Serial ECG (Figs. E1, E2, and E3).
- Almost any arrhythmia can occur, but simultaneous increased automaticity of cardiac tissue and conduction delay in the AV node should raise suspicion. Findings suggestive of toxicity include the following:
  1. Frequent premature ventricular complexes, bigeminy (Fig. E4)
  2. Bradyarrhythmias
  3. AV block
  4. Atrial tachycardia with AV block
  5. Junctional rhythms
  6. Ventricular arrhythmias: Ventricular tachycardia, ventricular fibrillation, bidirectional ventricular tachycardia (alternating QRS axis)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Ensure adequate airway, IV access
- Continuous cardiac monitor, pulse oximetry

ACUTE GENERAL Rx

DECREASE TOXICITY:

- Acute poisoning: Single dose of activated charcoal if within 2 hr of ingestion.
- Treat hypokalemia and hypomagnesemia; both potentiate toxicity.
- Most life-threatening complications of digoxin toxicity are treated with digoxin-specific antibody fragments (Fab).
- Digoxin-specific Fab fragments (DigiFab):
  1. Specific antibodies that bind to digoxin and to a lesser extent other cardiac glycosides. By binding to free digoxin, the plasma digoxin level decreases, facilitating dissociation of digoxin from the Na^+, K^+-ATPase.
  2. Initial response usually seen within 30 min, and complete reversal usually occurs within 4 hr.
  3. Indications: Hyperkalemia (>5.0 mEq/L), hemodynamic instability, severe arrhythmias, massive overdose (acute ingestion of ≥10 mg digoxin; acute ingestion resulting in steady-state serum level ≥10 ng/ml; chronic toxicity with level >6 ng/ml), coingestion of cardiotoxic drugs or plants containing cardiac glycosides.
  4. Dosing: 1 vial of Fab fragments binds 0.5 mg of digoxin. Round up when calculating number of vials to administer.

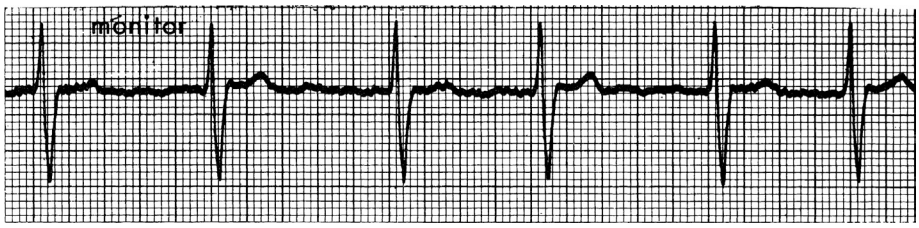

FIG. E1 Ventricular bigeminy caused by digoxin toxicity. Ventricular ectopy is one of the most common signs of digoxin toxicity. The underlying rhythm here is atrial fibrillation. (From Goldberger AL [ed]: *Clinical electrocardiography,* ed 5, St Louis, 1994, Mosby.)

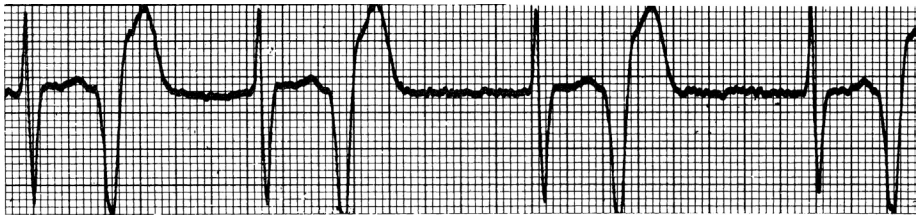

FIG. E2 Ventricular bigeminy caused by digoxin toxicity. In this figure, each normal QRS is followed by a ventricular premature beat. (From Goldberger AL [ed]: *Clinical electrocardiography,* ed 5, St Louis, 1994, Mosby.)

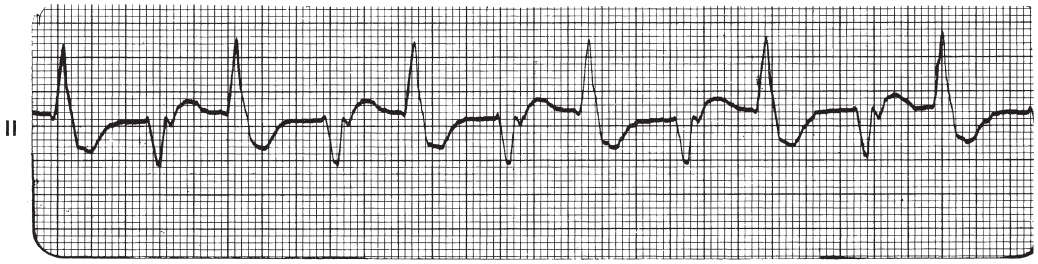

FIG. E3 This digoxin-toxic arrhythmia is a special type of ventricular tachycardia (bidirectional tachycardia) with QRS complexes that alternate in direction from beat to beat. No P waves are present. (From Goldberger AL [ed]: *Clinical electrocardiography,* ed 5, St Louis, 1994, Mosby.)

a. Acute ingestion of known amount: Number of vials = (ingested digoxin [mg] × B)/0.5; B = bioavailability for tablets (0.8) and capsules or IV (1.0)
b. Steady-state level known: Number of vials = (serum digoxin level [ng/ml]) × weight [kg]/100
c. If neither the amount ingested nor steady-state serum level is known, treat empirically:
   (1) Acute intoxication: 10 vials and repeat in 30 min if inadequate response
   (2) Chronic toxicity: 6 vials

NOTE: Underdosing of Fab fragments may result in rebound toxicity as free digoxin is released from tissue stores. In chronic toxicity without life-threatening symptoms, consider giving half the calculated dose initially to decrease the risk of exacerbating underlying heart disease.

- After use of Fab fragments, the free digoxin level decreases, but the measured digoxin level may increase because most assays measure free and bound digoxin levels. Serum levels are unreliable for days. Can measure free digoxin level if needed.
- Renal elimination: Half-life of inactive complex is 15 to 20 hr. Elimination of complex is prolonged in renal failure. May get recurrence of toxicity days later in patients with renal failure (complexes may dissociate before excretion), so require monitoring for >72 hr.
- Class C for pregnancy.
- Adverse effects of treatment:
  1. May undo desirable action of digoxin and exacerbate heart failure or increase ventricular response in previously controlled atrial fibrillation.
  2. Hypotension.
  3. Hypokalemia (as toxicity is corrected, potassium moves back into the cell and hypokalemia can develop); monitor potassium level hourly for 6 hours and then at least daily.
  4. Allergic reactions (higher if history of prior use): Serum sickness.

Hemodialysis, hemoperfusion, plasma exchange: Ineffective and not recommended for removal of digoxin or Fab-digoxin complex.

Digoxin toxicity not requiring Fab fragments: Hospitalize with cardiac monitoring. Monitor potassium and digoxin concentrations; serial ECGs.

COMPLICATIONS: These recommendations are temporizing measures until digoxin-specific Fab fragments can be given.

- Hyperkalemia: Due to redistribution; treatment to lower K^+ not recommended unless life threatening because hypokalemia may occur once toxicity is corrected with Fab fragments
- Hypotension: IV fluids
- Severe bradycardia and heart block:
  1. Atropine
  2. Cardiac pacing: Use with caution; may precipitate life-threatening ventricular arrhythmias
- Tachyarrhythmias:
  1. Lidocaine or phenytoin: Decrease ventricular automaticity without slowing AV node conduction.
  2. Avoid amiodarone, procainamide, beta-blockers, calcium channel blockers because they may increase ventricular arrhythmias/AV node block.
  3. Elective electrocardioversion is relatively contraindicated because it may precipitate ventricular fibrillation.

DISPOSITION

- Patients require inpatient continuous cardiac monitoring on medical or intensive care units depending on severity of toxicity.
- Prognosis is good with prompt treatment.
- Chronic poisoning is associated with higher mortality rate than acute poisoning.

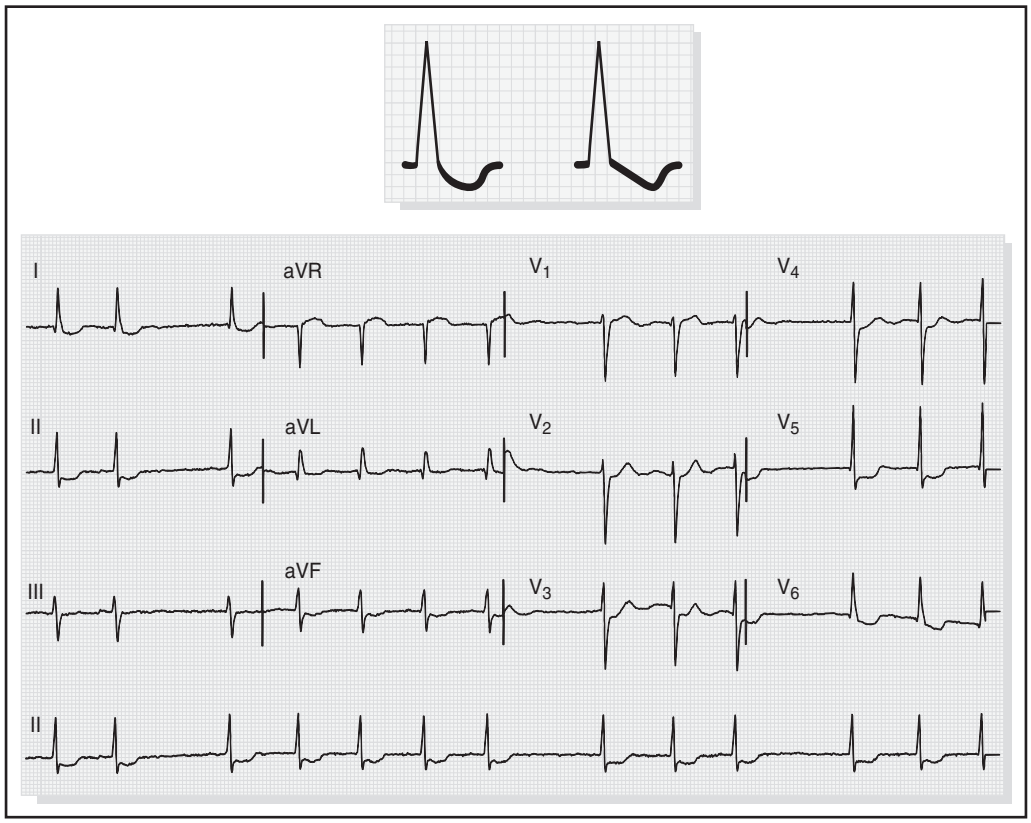

FIG. E4 *Top panel*, Digitalis effect. Digitalis glycosides characteristically produce shortening of the QT interval with a scooped or downsloping ST-T complex. *Bottom panels*, Digitalis effect in combination with digitalis toxicity. The underlying rhythm is atrial fibrillation. A group beating pattern of QRS complexes with shortening of the R-R intervals is consistent with nonparoxysmal junctional tachycardia with exit (AV Wenckebach) block. ST-segment depression and scooping (lead V_6) are consistent with the digitalis effect, although ischemia or left ventricular hypertrophy (LVH) cannot be excluded. Findings are strongly suggestive of digitalis excess; the serum digoxin level was higher than 3 ng/ml. The digitalis effect does not necessarily imply digitalis toxicity, however. *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right. (Top panel from Goldberger A: *Clinical electrocardiography*, ed 6, St. Louis, 1999, Mosby; From Bonow RO et al: *Braunwald's heart disease,* ed 9, Philadelphia, 2012, WB Saunders.)

REFERRAL

American Association of Poison Control Centers: 800-222-1222

PEARLS & CONSIDERATIONS

- High index of suspicion is necessary; the signs and symptoms of toxicity often are similar to those of the underlying disease.
- To minimize toxicity, digoxin levels should be checked if the patient's condition changes (e.g., weight loss, worsening renal function) or an interacting drug is started or stopped.
- Hyperkalemia in acute toxicity is suggestive of significant poisoning (reflects amount of Na^+, K^+-ATPase poisoning) and is associated with increased mortality.
- Falsely elevated digoxin levels may be seen in pregnant women, renal failure, liver disease, and heart failure due to the presence of an endogenous digoxin-like substance.
- Severe toxicity from ingestion of nondigoxin cardiac glycosides (e.g., plants) may present with low digoxin levels because of low cross-reactivity between these substances and the digoxin assay. Empiric dosing of Fab fragments should be used to treat these poisonings.

BASIC INFORMATION

DEFINITION

Diphtheria is an infection of the mucous membranes or skin caused by *Corynebacterium diphtheriae.*

Rarely, a similar disease can be caused by other *Corynebacterium* species, which may elaborate a toxin similar to toxigenic *C. diphtheriae.*

C. ulcerans, a zoonotic bacteria, has been most consistently implicated.

At least four biotypes of *C. diphtheriae* exist, including gravis, intermedius, mitis, and belfanti. Mitis strains usually cause less severe disease with less toxin production.

SYNONYMS

Pharyngeal diphtheria
Wound diphtheria
Diphtheric cardiomyopathy
Diphtheric polyneuropathy

ICD-10CM CODE
A36.9 Diphtheria, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Since 1980, the incidence in the U.S. has been about 0.001 cases per 100,000 population because of widespread vaccination.
PREDOMINANT AGE: Adult yr (in the U.S.)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

RESPIRATORY DIPHTHERIA:

- Commonly presenting as pharyngitis, but any part of the respiratory tract may be involved, including the nasopharynx, larynx, trachea, or bronchi
- Areas of gray or white exudate coalescing to form a "pseudomembrane" that bleeds when removed (Fig. E1)
- Possible fever and dysphagia
- Complications: Respiratory tract obstruction and pneumonia
- Systemic effects of the toxin: Myocarditis and polyneuritis (frequently involving a bulbar distribution), less often nephritis
- Occurs mostly in nonimmune individuals; usually milder and less likely to be complicated in those adequately immunized

CUTANEOUS DIPHTHERIA:

- Usually complicates existing skin lesion (i.e., impetigo or scabies)
- Resembles the underlying condition or presents as a nonhealing ulcer with a grayish membrane

ETIOLOGY

- Caused by *C. diphtheriae,* an aerobic, gram-positive rod
- Transmitted by close contact through droplets of nasopharyngeal secretions
- Symptomatic disease of the respiratory system caused by toxin-producing strains (tox^+)
- Systemic effects of toxin: Ranging from nausea and vomiting to polyneuropathy, nephritis, myocarditis, and vascular collapse
- Presence of strains not producing toxin (tox^+) in the respiratory tract of asymptomatic carriers and in skin lesions of cutaneous diphtheria
- Humans are the only known reservoir for *C. diphtheriae*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Streptococcal pharyngitis
- Viral pharyngitis
- Mononucleosis

WORKUP

- Presence of a pseudomembrane in the oropharynx suggestive of diagnosis (not always present)
- Gram stains of secretions to show club-shaped organisms, which appear as "Chinese letters"
- Nasolaryngoscopy to identify lesions in the nares, nasopharynx, larynx, or tracheobronchial tree

LABORATORY TESTS

- Cultures of mucosal lesions or of nasal discharge:
  1. Positive culture for *C. diphtheriae* confirms the diagnosis.
  2. Laboratory is notified of the suspected diagnosis so that appropriate culture medium (Tinsdale agar) is used.
- Testing of all isolated organisms for toxin production. The CDC Pertussis and Diphtheria Lab offers culture, toxin testing, PCR, and serology; phone: 404-639-1231.

Repeat cultures should be obtained 2 wk after completing therapy to ensure eradication of the bacteria.

IMAGING STUDIES

Chest x-ray to rule out pneumonia

TREATMENT

NONPHARMACOLOGIC THERAPY

- Intubation or tracheostomy if signs of respiratory distress occur
- Cardiac monitoring with serial ECGs, troponin measurements
- Nasogastric or parenteral nutrition in those with bulbar signs
- ICU monitoring for patients with signs of systemic toxicity
- Cardiac pacing in patients with heart block
- Respiratory isolation

ACUTE GENERAL Rx

- Administration of diphtheria antitoxin after a clinical diagnosis is made. Do not wait for laboratory confirmation of toxin production; give ASAP, as the effect of toxin is irreversible once it enters the host's cells.
- If test results for hypersensitivity to horse serum are negative: 20,000 to 40,000 units for pharyngeal/laryngeal disease present less than 48 hr, 40,000 to 60,000 units for nasopharyngeal disease, and 80,000 to 120,000 units for longer than 3 days of illness or diffuse neck swelling ("bull-neck") (available via the CDC).
- IV infusion of antitoxin over 60 min.
- Serum sickness in 10% of treated individuals; those with hypersensitivity to horse serum should be desensitized before administration of antitoxin.
- Antibiotics to eradicate the organism in carriers or patients.
- For respiratory diphtheria:
  1. Erythromycin 500 mg qid PO or IV (clarithromycin and azithromycin are acceptable alternatives) or IV penicillin G 25,000 to 50,000 units/kg to a maximum of 1.2 million units bid for 14 days. The course may be completed orally when able.
  2. Carriers or patients with cutaneous disease: Erythromycin 500 mg PO qid or IM penicillin.
  3. Patients should be given diphtheria toxoid vaccine during convalescence because disease neither interferes with nor confers immunity.
- Patients should be appropriately isolated: Droplet precautions for respiratory cases, contact for cutaneous cases.
- Contacts should be screened for prophylactic antibiotics.

CHRONIC Rx

Antibiotics to limit toxin production and eradicate carrier state, thereby preventing transmission

DISPOSITION

- Complete recovery with adequate supportive measures and antitoxin
- Cardiomyopathy is due to toxin and has a mortality rate of ~20% even with supportive care
- Neuropathy may not completely resolve

REFERRAL

- Hospitalization and referral to an infectious disease specialist for all suspected patients
- To an otolaryngologist for evaluation in cases of respiratory diphtheria
- All cases reported to the public health authorities

PEARLS & CONSIDERATIONS

COMMENTS

- Most cases are imported by travelers in epidemic areas, so recent epidemics in Eastern Europe are a cause for concern. A widespread epidemic of diphtheria began in 1990 in the former Soviet Union.
- Vaccination with diphtheria toxoid (attenuated toxin) is safe and effective in the form of DPT or Td; Td boosters should be given to adults every 10 yr. A new formulation of Tdap vaccine with reduced amounts of diphtheria toxoid and acellular pertussis antigens is available; it is well tolerated in clinical trials and provides excellent protection in adolescents and adults.
- According to serologic studies, 20% to 60% of U.S. adults >20 yr of age are susceptible to diphtheria.

BASIC INFORMATION

DEFINITION

Diplopia is the perception of two images of a single object that may be displaced horizontally, vertically, or obliquely. Diplopia may be monocular or binocular. Monocular diplopia is double vision in one eye and persists when the unaffected eye is covered. It is an ophthalmologic problem that results from abnormal light transmission to the retina. Binocular diplopia results from ocular misalignment and resolves when either eye is covered. There are multiple possible causes that can be localized along the visual pathway, from the eye to the brainstem.

SYNONYM

Double vision

ICD-10CM CODE
H53.2 Diplopia

EPIDEMIOLOGY & DEMOGRAPHICS

- Diplopia represents 1.4% of ophthalmologic emergencies.
- The majority of cases are binocular.

GENETICS: Some diseases have a genetic basis, such as Marfan syndrome (dislocation of lens), or to a lesser degree, autoimmune conditions (myasthenia gravis [MG], Graves) that have a possible genetic link.

RISK FACTORS: Risk factors for diplopia include risk factors for vasculopathies (e.g., hypertension, diabetes mellitus, smoking, cerebrovascular accident) or trauma.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Monocular diplopia persists when the unaffected eye is covered and, unless caused by a retinal defect, resolves when a pinhole is used.
- Restrictive, mechanical orbitopathy: Typically gradual in onset, with a sensation of mass effect/discomfort/pain in a single eye unless caused by thyroid disease, which may be unilateral or bilateral. It may be the result of rectus muscle entrapment secondary to orbital blowout fracture, or may be accompanied by fever if infectious in etiology. Diplopia that is worse in the morning may be attributed to Graves myopathy with proptosis, periorbital swelling, edema, palpebral swelling, conjunctival or scleral injection, and abrupt restriction of eye movement away from the affected muscle.
- Cranial nerve (CN; III, IV, or VI) palsy: May occur as an isolated nerve palsy as a result of microvascular ischemia, or in combination in the case of cavernous sinus or posterior orbit pathologies.
  1. CN III (oculomotor) palsy: Vertical and horizonal diplopia. Complete CN III palsy will have ptosis; large unreactive pupil; and paralysis of adduction, elevation, and depression so eye rests in position of abduction, depression, and intorsion.
  2. CN IV (trochlear) palsy: Vertical and/or torsional diplopia that worsens looking down and toward the nose; difficulty descending stairs, reading, or watching television in bed.
  3. CN VI (abducens) palsy: Horizontal diplopia that worsens on lateral gaze toward the affected side.
- Neuroaxial process: Diplopia may occur in isolation or may be accompanied by multiple neurological signs and symptoms; vertical diplopia without vertical skew deviation suggests a brainstem lesion.
- Neuromuscular disorder: Muscle atrophy/weakness, weakness on forced eyelid closure, normal reflexes, and no sensory deficits.

ETIOLOGY

- The etiology of diplopia differs between monocular and binocular diplopia. Monocular diplopia is caused by primary ophthalmologic structural problems in the transmission of light to the retina and generally should be referred to an ophthalmologist. Binocular diplopia, when not caused by trauma, is most often a vascular lesion (small-vessel vasculopathy or aneurysmal disease) or occasionally due to endocrinopathy, neuromuscular, neoplastic, or autoimmune sources.
- Table E1 summarizes important causes of diplopia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Psychogenic (functional deficit)
- Monocular diplopia:
  1. Dry eyes
  2. Corneal irregularity
  3. Astigmatism
  4. Cataract
  5. Lens dislocation
  6. Retinal wrinkles involving the macula
- Binocular diplopia:
  1. Restrictive, mechanical orbitopathy
     a. Abscess
     b. Trauma
     c. Entrapment
     d. Orbital myositis (may be associated with Wegener granulomatosis, giant cell arteritis, systemic lupus erythematosus, dermatomyositis, sarcoidosis, rheumatoid arthritis, Graves disease, or orbital pseudotumor)
     e. Craniofacial mass
  2. Cranial nerve (III, IV, or VI) palsy
     a. Isolated mononeuropathy of a single nerve
        (1) Demyelination (e.g., multiple sclerosis)
        (2) Hypertensive or diabetic vasculopathy
        (3) Nerve compression (e.g., aneurysm, tumor)
     b. Unilateral palsy of multiple oculomotor nerves
        (1) Infection, mass, or vasculitis affecting cavernous sinus or posterior orbit
  3. Neuroaxial process involving the brainstem
     a. Multiple sclerosis may manifest as a focal brainstem lesion.
     b. A more diffuse but localized brainstem lesion may result from brainstem tumor, brainstem lacunar stroke, basilar artery thrombosis, vertebral artery dissection, ophthalmoplegic migraine, infection, autoimmune disorder (e.g., Miller-Fischer or Guillain-Barré syndrome), Wernicke encephalopathy, meningoencephalitis, or botulism.
- Neuromuscular disorder
  1. Myasthenia gravis
  2. Lambert-Eaton syndrome

WORKUP

- Full neurologic examination with careful attention to the cranial nerves.
- Monocular diplopia: Slit-lamp, funduscopic examination, and ophthalmology referral.
- Diagnostic testing should be guided by clinical judgment as applied to the differential diagnosis. Imaging is the mainstay of the workup and is indicated in most cases of undifferentiated binocular diplopia. Laboratory studies are rarely helpful.
- Fig. E1 describes an algorithm for the diagnostic approach to diplopia.

LABORATORY TESTS

- Thyroid panel may be useful in cases of suspected thyroid disease.
- Lumbar puncture for meningitis or Miller-Fischer syndrome.

IMAGING STUDIES

- Magnetic resonance imaging (MRI) of the orbits with gadolinium is the test of choice in patients with suspected restrictive, mechanical orbitopathy; cavernous sinus; or posterior orbit pathology. Computed tomography (CT) of the head with contrast is a second-line option.
- For an isolated mononeuropathy, MRI of the brain and orbits with gadolinium is preferred. CT angiography (CTA) or magnetic resonance angiography (MRA) should be obtained in cases of suspected aneurysm. MRA should be used with caution when aneurysm is highly suspected because the sensitivity of MRA decreases with aneurysm size less than 5 mm.
- MRI with and without gadolinium is recommended for detection of brainstem lesions. The addition of a diffusion-weighted imaging protocol may be useful when ischemia is suspected.

TREATMENT

- The treatment of diplopia is directed at the underlying disorder
- Signs of basilar meningoencephalitis: Empiric antibiotics pending CT, lumbar puncture, and confirmation of infection
- Signs of Wernicke encephalopathy: Give thiamine
- Signs of stroke: IV fluid bolus and emergent evaluation for reperfusion therapy

TABLE E1 Important Causes of Diplopia

Diplopia-Causing Entity	Mechanism and Mortality	Distinguishing Features
Tier 1—Critical		
Basilar artery thrombosis	Acute thrombosis of the basilar artery with brainstem ischemia; untreated, mortality 70%-90%	Vertigo, dysarthria, other cranial nerve involvement; risk factors for stroke
Botulism	Toxin inhibits release of acetylcholine (ACh) at cholinergic synapses and presynaptic myoneural junctions; untreated, mortality 60%	Dysarthria, dysphagia, autonomic dysreflexia, pupillary dysfunction
Basilar meningitis	Infection; untreated, mortality close to 100% if bacterial (25%-40% if treated)	Headache, meningismus, fever
Aneurysm	Enlarging aneurysm directly compresses cranial nerve; untreated, rupture risk is 1% per yr; mortality 26%-50% per rupture	CN III palsy with pupillary involvement
Tier 2—Emergent		
Vertebral dissection	Dissection causes vertebrobasilar ischemia; acute untreated, mortality 28% (2%-5% if neurologically asymptomatic)	Neck pain, vertigo; risk factors for vertebral dissection
Myasthenia gravis	Autoantibodies develop against ACh nicotinic postsynaptic receptors; untreated, crisis mortality 42% (5% if treated)	Fluctuating muscle weakness, ptosis, and diplopia worsen with activity and improve with rest
Wernicke encephalopathy	Thiamine-dependent metabolic failure and tissue injury; untreated, mortality 20%	Nystagmus, ataxia, altered mental status, and ophthalmoplegia; risk factors and nutritional deficiency
Orbital apex syndrome, cavernous sinus process	Inflammation or infection in the orbital apex or cavernous sinus directly affects oculomotor cranial nerves; acute mortality low unless infectious and complicated by meningitis	A combination of palsies of CN III, IV, or VI, with retroorbital pain, conjunctival injection, and possible periorbital or facial numbness
Tier 3—Urgent		
Brainstem tumor	Tumor involvement at the supranuclear level; acute mortality low (long-term mortality variable)	Skew deviation vertical diplopia, internuclear ophthalmoplegia
Miller-Fisher syndrome	Autoantibodies develop to a cranial nerve ganglioside, GQ1b; acute mortality low if fully differentiated from GBS; mortality 2%-12% if GBS	Ophthalmoplegia, ataxia, areflexia
Multiple sclerosis	Demyelinating lesions; acute mortality low	Internuclear ophthalmoplegia
Thyroid myopathy (Graves disease)	Autoimmune myopathy; acute mortality low with regard to ocular complaints	Proptosis, restriction of elevation and abduction of the eye, signs of Graves disease
Ophthalmoplegic migraine	Inflammatory cranial neuropathy; low mortality—self-limited disease	Ipsilateral headache, CN (usually III) palsy
Ischemic neuropathy	Microvascular ischemia; mortality low—self-limited disease	Isolated CN palsy (pupil-sparing if CN III)
Orbital myositis, pseudotumor	Autoimmune or idiopathic myositis; acute mortality low with regard to ocular complaints	Eye pain, restriction of movement, periorbital edema; exophthalmos and chemosis when more severe
Orbital apex mass	A tumor, infiltration, or mass effect in the orbital apex or cavernous sinus directly compresses oculomotor cranial nerves; acute mortality low	A combination of palsies of CN III, IV, or VI, and possible periorbital or facial numbness, with retroorbital pain, proptosis, signs of venous congestion

CN, Cranial nerve; *GBS*, Guillain-Barré syndrome.
From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, Saunders.

DISPOSITION

Most patients will require hospital admission for further evaluation and treatment. However, a CN III or CN IV palsy from microvascular ischemia typically self-resolves over a few days; these patients can usually be followed on an outpatient basis for spontaneous resolution.

PEARLS & CONSIDERATIONS

- All patients with diplopia merit a thorough neurologic examination.
- Consider potential critical and emergent causes, including infection, stroke, and Wernicke encephalopathy.
- Treat the underlying problem.
- Most patients merit hospital admission.

PREVENTION

No specific prevention has been published, although it stands to reason that preventing the antecedent vascular insults by managing hypertension and diabetes, as well as avoiding tobacco use and trauma, should have an impact on the disease prevalence.

PATIENT & FAMILY EDUCATION

Patients should be counseled to avoid driving or performing tasks that could be considered dangerous with impaired vision until symptoms resolve.

BASIC INFORMATION

DEFINITION

Discoid lupus erythematosus (DLE) is a chronic inflammatory autoimmune cutaneous disorder that can lead to significant disfiguration and scarring. It can be associated with or occur independently of systemic lupus erythematosus (SLE).

SYNONYM

Discoid lupus

ICD-10CM CODES

L93.0 Discoid lupus erythematosus
L93.2 Other local lupus erythematosus

EPIDEMIOLOGY & DEMOGRAPHICS

- Slightly more common in African Americans than in Asians or whites.
- DLE is two to three times more likely in women than in men.
- DLE most commonly occurs on the face, scalp, and ears, but can also appear on mucosal surfaces such as the conjunctiva, nasal mucosa, and lips.
- DLE is the most common chronic cutaneous manifestation of SLE, occurring in nearly 20% of SLE patients.
- Approximately 5% to 10% of patients presenting with DLE will develop SLE; those with widespread, numerous lesions are more likely to progress.
- Highest prevalence of SLE occurs in persons ages 40 to 60, with SLE onset most often occurring in patients in their 20s and 30s.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

General:

- Early lesions: Single or multiple erythematous or violaceous, discrete papules or plaques with scale (Figs. E1 and E2), often extending into dilated hair follicles (follicular plugging). Intense inflammatory nature results in an indurated feel on palpation (Fig. E3).
- Older lesions: Peripheral hyperpigmentation with scarring, central hypopigmentation, atrophy (Fig. E4), and telangiectasia.
- Table E1 summarizes features of drug-induced lupus erythematosus.

Anatomic distribution:

- Commonly involves the scalp, face, ears (conchal bowls), and extensor surface of the arms (photodistributed pattern).
- Mucosal and nail involvement is also possible.

Lesion configuration:

- Irregularly grouped, confluent and disfiguring plaques

Lesion morphology:

- Erythematous plaque with scale
- Rarely, hypertrophic plaques with thick scale
- Follicular plugging
- Atrophy
- Irreversible, scarring alopecia (34%)
- May be associated with other clinical findings of SLE (e.g., oral ulcers, arthritis, pleuritis, pericarditis)

FIG. E1 Discoid lupus erythematosus (DLE). This young girl showed well-circumscribed, elevated, indurated, red to purplish annular plaques of DLE. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E2 Discoid lupus erythematosus (DLE). The ear is often involved with DLE. Note the well-defined plaques of purplish erythema, focal overlying scaling, and postinflammatory hyperpigmentation and depigmentation. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Classic discoid lupus erythematosus of the face. Note central scarring and erythematous hyperkeratotic borders. (From Hochberg MC et al: *Rheumatology*, ed 5, St Louis, 2011, Mosby.)

ETIOLOGY

Unknown, but thought to be an autoimmune-mediated disorder and due to interaction between environmental and genetic factors

Dx DIAGNOSIS

Clinical findings and skin biopsy are used to establish the diagnosis of DLE.

DIFFERENTIAL DIAGNOSIS

- Table E2 compares various cutaneous connective tissue diseases
- Burn scar
- Dermatophyte infection
- Granuloma annulare
- Granuloma faciale
- Lichen planus
- Lichen planopilaris
- Psoriasis
- Radiation dermatitis
- Rosacea
- Sarcoidosis
- Scarring alopecia
- Subacute cutaneous lupus erythematosus
- Syphilis
- Vitiligo

LABORATORY TESTS

- Complete blood count is usually normal in isolated DLE.
- Blood urea nitrogen and creatinine are normal in isolated DLE.
- Erythrocyte sedimentation rate is elevated in active disease.
- Urinalysis may show proteinuria.
- Antinuclear antibody is positive in 20% of patients with isolated DLE.
- Anti-Ro (SS-A) and anti-La (SS-B) autoantibodies are present in 1% to 3% of patients.
- Histology of skin biopsy is diagnostic and reveals hyperkeratosis with follicular plugging; interface dermatitis with Civatte bodies; melanophages at dermal-epidermal junction; a thickened basement membrane; and a perivascular, interstitial, and perifollicular lymphocytic infiltrate.

FIG. E4 Discoid lupus erythematosus. Dyspigmentation and atrophy of the hard palate. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Avoid sun exposure by using protective clothing and a broad-spectrum sunscreen of SPF >30 that blocks UVB and UVA light (e.g., avobenzone with octocrylene, titanium dioxide, zinc oxide). Avoid exposure to sunlight during peak hours. Use sun-protective clothing.

ACUTE GENERAL Rx

- Topical steroids: Intermediate- to high-potency steroids are needed; use caution when applying to the face
- Intralesional triamcinolone acetonide (3 to 10 mg/cc)
- Topical calcineurin inhibitors: Pimecrolimus 1% cream and tacrolimus 0.1% ointment
- Systemic antimalarials: Hydroxychloroquine sulfate 200 mg PO bid alone or in combination with quinacrine 100 mg PO daily
- Avoid use of systemic glucocorticoids in patients with isolated DLE because of risks of side effects

CHRONIC Rx

- Antimalarials remain the cornerstone of treatment: Hydroxychloroquine 6 mg/kg of ideal body weight per day or chloroquine 4 mg/kg of ideal body weight per day. Combination therapy with quinacrine can also be used.
- Second-line agents are methotrexate, acitretin, isotretinoin, and dapsone. Labs should be followed regularly on these medications.

TABLE E1 Features of Drug-Induced Lupus Erythematosus

	Skin Features	Noncutaneous Signs	Laboratory Findings	Most Common Pediatric Trigger(s)
Drug-induced SLE	Photosensitivity, purpura, erythema nodosum, urticaria and urticarial vasculitis, necrotizing vasculitis Usually absent: Malar or discoid rash (except TNF inhibitors), mucosal ulcers, alopecia, Raynaud phenomenon	Fever, arthralgias, myalgias, pericarditis, pleuritic, sometimes hepatitis Usually absent: CNS, renal, pulmonary involvement Hepatic changes from minocycline	ANA, antihistone antibodies, elevated ESR May be mild cytopenia	Minocycline, occasionally TNF-α inhibitors
Drug-induced SCLE	Annular polycyclic lesions and/or papulosquamous lesions, including on legs Less commonly, erythema multiforme-like or vesiculobullous lesions, necrotizing vasculitis	Usually no arthritis, serositis, or major organ involvement	ANA, anti-Ro, anti-La	Terbinafine, griseofulvin NSAIDs (piroxicam, naproxen)
Drug-induced CCLE	Discoid lesions in photosensitive distribution	Usually no other signs	ANA	TNF-α inhibitors

ANA, Antinuclear antibody; *CCLE,* chronic cutaneous lupus erythematosus/discoid lupus; *CNS,* central nervous system; *ESR,* erythrocyte sedimentation rate; *NSAID,* nonsteroidal antiinflammatory drug; *SCLE,* subacute cutaneous lupus erythematosus; *SLE,* systemic lupus erythematosus; *TNF,* tumor necrosis factor.
From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.

TABLE E2 Autoimmune Cutaneous Connective Tissue Diseases

Autoimmune Disease	Indirect Immunofluorescence Pattern of Antinuclear Antibody Staining in Serum*	Nuclear Antigens to Which Autoantibodies Are Directed	Direct Immunofluorescence of Tissue
Lupus Erythematosus			
Systemic LE	Peripheral (rim), homogeneous, nucleolar, speckled	nDNA or double-stranded DNA, single-stranded DNA, histones, nucleolar RNA, various ribonucleoproteins, cardiolipin, Sm (Smith), U1-snRNP, HMG-17	Two or more granular immunoglobulin and complement deposits at BMZ, IgG, IgM, and/or IgA with C3 in involved and uninvolved skin (lupus band); lichenoid changes with numerous cytoids and shaggy fibrinogen staining of BMZ also found
Discoid LE	Usually no circulating antibodies	Usually none detected	Two or more granular immunoglobulin and complement deposits at BMZ, IgG, IgM, and/or IgA with C3 in involved skin; lichenoid changes with numerous cytoids and shaggy fibrinogen staining of BMZ also found
Subacute cutaneous LE	Fine speckled or speckled, may be negative	SS-A/Ro, SS-B/La	Particulate intercellular staining with or without granular immune deposits at BMZ or lichenoid changes
Neonatal LE	Fine speckled or speckled, may be negative	SS-A/Ro, SS-B/La	Granular IgG (transplacental) at BMZ
Drug-induced LE	Peripheral, homogeneous	Histones	Granular immune deposits at the BMZ
Scleroderma			
Cutaneous scleroderma (localized and generalized morphea)	Peripheral	SCL-70, SS-A/Ro, SS-B/La	No characteristic changes; vascular staining may be observed
Limited disease (acrosclerosis, CREST)	Centromere	Centromere, SCL-70, U1-snRNP, HMG-17	No characteristic changes; vascular staining may be observed
Diffuse disease (systemic sclerosis)	Nucleolar, speckled	SCL-70, U1- and U3-snRNP, RNA pol I, II, and III	No characteristic changes; vascular staining may be observed
Dermatomyositis, polymyositis	Speckled, nucleolar	Jo-1, PM-Scl, Mi-2, U1-snRNP, SS-A/Ro	No characteristic changes; lichenoid features and vascular staining may be observed
Sjögren syndrome	Fine speckled, nucleolar	SS-A/Ro, SS-B/La, histones, U1-snRNP	No characteristic changes; vascular staining may be observed
Mixed connective tissue disease	Speckled	U1-snRNP, PM-Scl	No characteristic changes; granular immune deposits at the BMZ lichenoid features and vascular staining may be observed
Overlap and undifferentiated connective tissue disease	Any single or combination pattern	Any one or multiple	
PM-Scl	May show granular immune complex deposition at BMZ (lupus band), vascular staining, or lichenoid changes		

BMZ, Basement membrane zone; *CREST,* calcinosis, Raynaud phenomenon, esophageal dysfunction, sclerodactyly, and telangiectasia; *DNA,* deoxyribonucleic acid; *Ig,* immunoglobulin; *LE*, lupus erythematosus; *nDNA,* nuclear DNA; *RNA,* ribonucleic acid.
From Adkinson NF et al: *Middleton's allergy principles and practice*, ed 8, Philadelphia, 2014, WB Saunders.

- Third-line agents are azathioprine, thalidomide, mycophenolate mofetil, sulfasalazine, and oral gold.
- Oral corticosteroids can be considered in resistant cases with associated symptoms refractory to other measures.

DISPOSITION

If untreated, DLE can lead to significant and permanent atrophy and scarring of the skin.

REFERRAL

Dermatology, rheumatology, nephrology, internal medicine, ophthalmology

PEARLS & CONSIDERATIONS

- Discoid rash is one of 11 diagnostic criteria for SLE.
- Rarely, patients with DLE may develop cutaneous squamous cell carcinoma in areas of disease.
- It is unusual to see DLE involving areas below the neck if there is no disease above the neck. Biopsy for definitive diagnosis in these cases.
- Localized DLE is associated with SLE in 5% to 10%.
- Generalized DLE is associated with SLE in 15% to 28%.

Disseminated Intravascular Coagulation

BASIC INFORMATION

DEFINITION

Disseminated intravascular coagulation (DIC) is an acquired thromboembolic disorder characterized by generalized activation of the clotting pathways, which results in the intravascular formation of fibrin and ultimately thrombotic occlusion of small and midsize vessels, followed by end-organ damage.

SYNONYMS

Consumptive coagulopathy
DIC
Defibrination syndrome

ICD-10CM CODE
D65 Disseminated intravascular coagulation [defibrination syndrome]

EPIDEMIOLOGY & DEMOGRAPHICS

About 1% of hospitalized patients may have evidence of DIC. There is no predilection for age or gender. More than 50% of cases are associated with gram-negative sepsis or other septicemic infections, and up to 35% of patients with severe sepsis have DIC.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

DIC occurs in both acute and chronic forms and can present with bleeding, thrombosis, or laboratory evidence of clotting cascade activation and fibrinolysis without evident clinical sequelae. Acute DIC is more common and predominantly manifests as bleeding complications. The risk of bleeding increases with worsening thrombocytopenia and is fivefold higher when platelet count is below $<50 \times 10^9$/liter. Sudden exposure to procoagulants may extensively activate a coagulation cascade and platelet consumption, resulting in thrombosis. In contrast, chronic DIC more frequently causes thrombotic complications. The diagnosis of chronic DIC can be challenging, as the PT and PTT are frequently normal. Multiple pathways are involved simultaneously in DIC to create the clinical presentation. These include: (1) thrombin generation due to release of tissue factor, (2) suppression of physiologic anticoagulant (e.g., protein C or antithrombin insufficiency), (3) impaired fibrinolysis characterized by increased level of plasminogen activator inhibitor type 1 (PAI-1), and (4) activation of inflammatory pathways.

With DIC, multiple organs may be involved, and clinical presentations may vary. They can include:

- Central nervous system: Altered mental status, transient neurological deficits
- Cardiovascular: Hypotension, tachycardia
- Respiratory: Hypoxia, dyspnea, localized rales, and acute respiratory syndrome
- Gastrointestinal: Intestinal bleeding, bowel infarction
- Genitourinary: Oliguria, anuria, uremia, acidosis, metrorrhagia
- Skin: Wound site bleeding, epistaxis, gingival bleeding, hemorrhagic bullae, petechiae, ecchymosis, purpura

ETIOLOGY

DIC results from the aberrant and generalized activation of the clotting system, resulting in simultaneous formulation of coagulation and fibrinolysis. Clotting factors are consumed at a rate in excess of the capacity of the liver to synthesize them, and platelets are consumed in excess of the capacity of the bone marrow megakaryocytes to release them. It frequently occurs in the setting of severe infection; common triggers are listed below:

- Infections (e.g., gram-negative sepsis, Rocky Mountain spotted fever, malaria, viral or fungal infection)
- Obstetric complications (e.g., fetal demise, amniotic fluid embolism, toxemia, abruptio placentae, septic abortion, eclampsia, placenta previa, uterine atony)
- Tissue trauma (e.g., burns, hypothermia rewarming)
- Malignancy (e.g., adenocarcinomas [gastrointestinal, prostate, lung, breast], lymphoproliferative/myeloproliferative; DIC is a hallmark of acute promyelocytic leukemia and a main cause of mortality.)
- Quinine, cocaine-induced rhabdomyolysis
- Liver failure
- Acute pancreatitis
- Transfusion reactions
- Respiratory distress syndrome
- Toxins (snake bites, amphetamine overdose)
- Other: Systemic lupus erythematosus (SLE), vasculitis, aneurysms, polyarteritis, hemangiomas with thrombocytopenia, and consumptive coagulopathy (Kasabach-Merritt syndrome)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hepatic necrosis: Normal or elevated factor VIII concentrations
- Vitamin K deficiency: Normal platelet count
- Hemolytic uremic syndrome: Coagulation assays are usually normal
- Thrombotic thrombocytopenic purpura: Low ADAMTS13 activity
- Renal failure, SLE, sickle cell crisis, dysfibrinogenemias
- HELLP syndrome (**h**emolysis, **e**levated **l**iver function tests, and **l**ow **p**latelets)

WORKUP

The diagnostic workup includes laboratory testing to characterize the coagulopathy and its severity and exclude conditions noted in the differential diagnosis (Tables 1 and 2, Box 1). Additional workup is guided by the clinical scenario and may include distinguishing DIC progression (acute vs. chronic), chief manifestations (thrombotic or hemorrhagic), and extent (localized or systemic).

LABORATORY TESTS

- Peripheral blood smear generally shows red blood cell fragments (schistocytes) and low platelet counts.
- Coagulation testing: Diagnostic characteristics of DIC are decreased fibrinogen level; thrombocytopenia; and increased prothrombin time (PT), partial thromboplastin time (PTT), thrombin time (TT), fibrin split products, and D-dimer.
- Coagulopathy secondary to DIC must be differentiated from other coagulopathies that result from underproduction of clotting

TABLE 1 Differential Diagnosis of Thrombocytopenia in Suspected Disseminated Intravascular Coagulation

Differential Diagnosis	Additional Diagnostic Clues
DIC	Prolonged aPTT and PT, increased FDP, low levels of antithrombin or protein C
Sepsis without DIC	Positive (blood) cultures, positive sepsis criteria, hemophagocytosis in bone marrow
Massive blood loss	Major bleeding, low hemoglobin, prolonged aPTT and PT
Thrombotic microangiopathy	Schistocytes evident on blood smear, Coombs-negative hemolysis, fever, neurologic symptoms, renal insufficiency, coagulation tests usually normal, ADAMTS13 levels decreased
Heparin-induced thrombocytopenia	Use of heparin, venous or arterial thrombosis, positive HIT test (usually immunoassay for heparin-platelet factor 4 antibodies), increase in platelet count after cessation of heparin; coagulation tests usually normal
Immune thrombocytopenia	Antiplatelet antibodies, normal or increased number of megakaryocytes in bone marrow aspirate, normal levels of TPO (TPO levels are usually normal or slightly increased in ITP); coagulation tests usually normal
Drug-induced thrombocytopenia	Decreased number of megakaryocytes in bone marrow aspirate or detection of drug-induced antiplatelet antibodies, increase in platelet count after cessation of drug; coagulation tests usually normal

ADAMTS13, A disintegrin and metalloproteinase with thrombospondin 13; *aPTT,* activated partial thromboplastin time; *DIC,* disseminated intravascular coagulation; *FDP,* fibrin degradation products; *HIT,* heparin-induced thrombocytopenia; *PT,* prothrombin time; *ITP,* immune thrombocytopenia; *TPO,* thrombopoietin.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 2 Differential Diagnosis of Prolonged aPTT and/or PT in Suspected Disseminated Intravascular Coagulation

Test Result	Cause
PT prolonged, aPTT normal	Factor VII deficiency Mild vitamin K deficiency Mild liver insufficiency Low doses of vitamin K antagonists
PT normal, aPTT prolonged	Factor VIII, IX, or XI deficiency Unfractionated heparin Inhibitory antibody and/or antiphospholipid antibody Factor XII or prekallikrein deficiency
Both PT and aPTT prolonged	Factor X, V, II, or fibrinogen deficiency Severe vitamin K deficiency Vitamin K antagonists Global clotting factor deficiency • Decreased synthesis: Liver failure • Increased loss: Massive bleeding, DIC

aPTT, Activated partial thromboplastin time; *PT,* prothrombin time.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

BOX 1 Diagnostic Algorithm for the Diagnosis of Overt Disseminated Intravascular Coagulation[a]

- Presence of an underlying disorder known to be associated with disseminated intravascular coagulation (DIC) (Table 2) (no = 0, yes = 2)
- Score global coagulation test results
  1. Platelet count (>100 = score 0; <100 = score 1; <50 = score 2)
  2. Level of fibrin markers (e.g., D-dimer, fibrin degradation products) (no increase = score 0; moderate increase = score 2; strong increase = score 3)[b]
  3. Prolonged prothrombin time (<3 s = score 0; >3 s but <6 s = score 1; >6 s = score 2)
  4. Fibrinogen level (>1.0 g/L = score 0; <1.0 g/L = score 1)

Calculate score

If ≥5: Compatible with overt DIC; repeat scoring daily if <5: Suggestive (not affirmative) for nonovert DIC; repeat next 1–2 days.

[a]According to the Scientific Standardization Committee of the International Society of Thrombosis and Haemostasis.
[b]Strong increase, greater than 5× upper limit of normal; moderate increase, greater than upper limit of normal but less than 5× upper limit of normal.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

factors, including liver disease or vitamin K deficiency.

1. Vitamin K deficiency manifests with prolonged PT but normal PTT, TT, platelet, and fibrinogen levels; PTT may be elevated in severe cases.
2. Patients with liver disease have abnormal PT and PTT; TT and fibrinogen are usually normal unless severe disease is present; platelets are usually normal unless splenomegaly is present.
3. Factor VIII is not synthesized exclusively by the liver. It can differentiate between DIC, where it is low, and coagulopathy of liver disease, where it is normal.

IMAGING STUDIES

Imaging studies are generally not useful. Imaging may be helpful for identifying sequelae of DIC, including chest radiographs to exclude infectious processes in patients with pulmonary symptoms such as dyspnea, cough, or hemoptysis.

Rx TREATMENT

ACUTE GENERAL Rx

- Correcting and eliminating the underlying cause is often sufficient to halt DIC (e.g., antimicrobial therapy for infection, removal of necrotic bowel, evacuation of uterus in obstetric emergencies).
- Patients with bleeding should be given replacement therapy with fresh frozen plasma (FFP) and platelets:
  1. FFP 10 to 15 ml/kg can be given with a goal of normalizing international normalized ratio.
  2. Platelet transfusions are given when platelet count is <10,000 (or higher if major bleeding is present).
  3. Cryoprecipitate 1 U/5 kg is given for low fibrinogen. It also can be given for prevention of bleeding in patients with fibrinogen level <100 mg/dl.
  4. Patients with extensive thrombosis (e.g., in acute promyelocytic leukemia, purpura fulminans, acral ischemia) require anticoagulation, despite thrombocytopenia and abnormal coagulation parameters. Heparin therapy using unfractionated heparin at lower doses than those used in venous thrombosis may be useful with a view to increase neutralization of thrombin. Low-molecular-weight heparin also may be used in this scenario.
- The mainstays of supportive treatment of DIC are summarized in Box E2.

DISPOSITION

Mortality rate in severe DIC exceeds 75%. The high mortality rate is often due to the severity of the underlying trigger and complications including acute renal failure, intracerebral bleeding, shock, or cardiac tamponade.

REFERRAL

Hematology consultation is recommended in all cases of severe DIC and DIC with hemorrhagic or thrombotic complications.

PEARLS & CONSIDERATIONS

COMMENTS

The treatment of chronic DIC is controversial. Low-dose SC heparin and/or combination antiplatelet agents such as aspirin and dipyridamole may be useful.

BOX E2 Mainstays of Supportive Treatment of Disseminated Intravascular Coagulation

Modality	Details	Expectations/Rationale
Treating the underlying disorder	Dependent on the primary diagnosis	Inhibit or block the complicating pathologic mechanism of disseminated intravascular coagulation (DIC) in parallel with the response (if any) of the disorder
Antithrombotic agents	Prophylactic heparin to prevent venous thromboembolic complications	Risk of thromboembolism is increased in critically ill patients, trauma patients, or patients with cancer
	(Low-dose) therapeutic heparin in case of confirmed thromboembolism or if clinical picture is dominated by (micro) vascular thrombosis and associated organ failure	Prevent fibrin formation; tip the balance within the microcirculation toward anticoagulant mechanisms and physiologic fibrinolysis; allow reperfusion of the skin, kidneys, and brain
Transfusion	Infuse platelets, plasma, and fibrinogen (cryoprecipitate) if there is overt bleeding or a high risk of bleeding	Bleeding should diminish and stop over the course of hours Platelet count, coagulation tests, and fibrinogen should return toward normal
Anticoagulant factor concentrates	Recombinant human activated protein C may be effective in sepsis and DIC (24 μg/kg per hour for 4 days); currently withdrawn from the market	Restore anticoagulation in microvascular environment and may have antiinflammatory activity Latest trials were negative.
Fibrinolytic inhibitors	Tranexamic acid (e.g., 500–1000 mg q8–12 h or ε-aminocaproic acid 1000–2000 mg q8–12 h)	May be useful if there is (hyper)fibrinolysis Bleeding ceases, but there is a risk of microvascular thrombosis and renal failure

BASIC INFORMATION

DEFINITION

Dissociative disorders (DDs) feature a disturbance in identity, memory, perception, and consciousness and include dissociative identity disorder (DID), dissociative amnesia (DA), dissociative fugue (DF), and depersonalization/derealization disorder (DPD).

SYNONYMS

DD
DID
DA
DF
DPD

ICD-10CM CODES

F44.81	Dissociative identity disorder
F44.0	Dissociative amnesia
F44.1	Dissociative amnesia with dissociative fugue
F48.1	Depersonalization/derealization disorder
F44.89	Other specified dissociative disorder
300.14	Dissociative identity disorder
300.12	Dissociative amnesia
300.13	Dissociative amnesia with dissociative fugue
300.6	Depersonalization/derealization disorder
300.15	Other specified dissociative disorder
300.15	Dissociative disorder, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Limited research documents the incidence of DDs, and estimates vary based on the assessment utilized and the sample studied.
PEAK INCIDENCE: Age of peak incidence varies by the type of DD.
PREVALENCE: The prevalence of DDs using various screening instruments is estimated to be 10%, with higher rates evidenced in studies of individuals seeking psychiatric care. The estimated prevalence of dissociative experiences in the general population is much higher.
PREDOMINANT SEX AND AGE: Females are diagnosed with DDs more frequently than males. Diagnoses may be made among individuals of all ages; however, the age of onset is thought to vary by subtype. Specifically, DID is thought to begin in childhood during the course of severe or prolonged trauma, whereas other DDs are thought to begin within the immediate context of stressful events at any age.
GENETICS: There is some evidence that biologic differences may play a role the likelihood of dissociation following the experience of trauma.
RISK FACTORS: DDs have been linked to experiencing chronic stress, especially during adolescence, as well as experiencing or witnessing acute traumatic events. A greater frequency of severe childhood sexual abuse is a significant specific predictor of dissociative disorders.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- **Dissociative amnesia (DA)**: Loss of autobiographic memory for previous experiences or before a certain point in time. Types of DA include:
  1. Localized amnesia: Inability to recall a specific (traumatic) period of time.
  2. Selective amnesia: Inability to recall parts, but not all, of a specific period of time.
  3. Systematized amnesia: Inability to recall categorical autobiographical memories, but not memory loss in chronologic order such as with localized amnesia.
  4. Continuous amnesia: Anterograde loss of memory, or inability to remember successive events as they occurred.
  5. Generalized (global) amnesia: Inability to recall one's whole life, including personal details.
  6. Thematic amnesia (as seen in DID and dissociative disorders not otherwise specified [DDNOS]): As identity states change, ability to recall specific periods of time is altered.
- **Dissociative fugue (DF):** DF carries the same characteristics as DA, with the distinguishing feature of sudden and unplanned purposeful travel away from one's home.
- **Dissociative identity disorder (DID):** Formerly referred to as *multiple personality disorder* (MPD), patients appear to possess two (or more) distinct identities or personality states, associated with the patient's consciousness, perception, thoughts, and actions.
- **Depersonalization disorder (DPD):** Also known as *derealization disorder,* DPD is a state in which patients believe that they have been altered in some way or that they are no longer real. Features include persistent and recurring experiences of feeling detached from one's own body and mental processes (i.e., one observing oneself as an outsider). Reality testing remains intact.
- **Dissociative disorders not otherwise specified (DDNOS):** Some dissociative symptoms of varying degrees but not meeting criteria for a distinct diagnosis.

ETIOLOGY

DDs are thought to develop after experiencing severe emotional or physical trauma. There is limited understanding of the neurobiologic underpinnings of DDs. However, research indicates that individuals with DPD report blunted reactions to arousing stimuli, suggesting that DDs may be caused by problems in connections between sensory systems (i.e., eyesight, hearing) and the limbic system. Other studies indicate variations in serotonin, endogenous opioid, and glutamate systems among individuals with DPD. Other studies document decreased blood flow in the right frontotemporal cortex of individuals with DA. Alterations in brain regions associated with emotion processing and memory, attention and interoceptive awareness, filtering of sensory input, self-referential processes, cognitive control, and arousal modulations have been linked to dissociative disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- DDs should be distinguished from acute substance intoxication, withdrawal, or substance-induced persisting amnestic disorder.
- Symptoms due to the physiologic consequences of a medical condition should be diagnosed as a mental disorder NOS due to a general medical condition.
- DA should be distinguished from amnestic disorder due to a brain injury, transient global amnesia, seizure disorders, delirium, dementia, age-related cognitive decline, and nonpathologic forms of amnesia (i.e., amnesia for sleep, memory loss).
- DA and DPD should not be diagnosed separately if symptoms occur only during the course of DF.
- DPD should not be diagnosed when symptoms occur only during a panic attack or in the context of panic disorder, specific phobia, or posttraumatic or acute stress disorders.
- If fugue symptoms occur only in the context of DID, DF should not be diagnosed separately.
- DID diagnoses take precedence over diagnosis of other DDs (i.e., DA, DF, DPD).
- Purposeful travel that occurs during a manic episode should be distinguished from a DF.
- Differential diagnosis should also consider schizophrenia and other psychotic disorders, bipolar disorder with rapid cycling, anxiety disorders, somatization disorders, and personality disorders.
- Amnesia for trauma may also occur in posttraumatic stress disorder and acute stress disorder.
- Clinicians may also consider malingered amnesia and malingered fugue states.

WORKUP

Diagnosis is made based on structured clinical interviews such as Dissociative Disorders Interview Schedule (DDIS) or the Structured Clinical Interview for Dissociative Disorders (SCID-D). The Dissociative Experiences Scale (DES) is a self-questionnaire diagnostically useful in DDs. Diagnosis also includes a review of personal history and symptoms as well as ruling out any physical injury (i.e., head trauma).

TREATMENT

There are currently no FDA-approved drugs for the treatment of DDs. Clinicians may consider FDA-approved medications (i.e., antianxiety medications, antidepressants, or antipsychotics) to treat co-occurring mood and anxiety symptoms associated with DDs.

NONPHARMACOLOGIC THERAPY

Psychotherapy for DDs generally proceeds in three phases. Phase 1 focuses on stabiliza-

tion and symptom control, education about treatment, affect and impulse regulation skill building, increasing awareness of dissociated self-states, and establishment of a therapeutic alliance. Phase 2 focuses on processing of traumatic memories, resolution of trauma-related cognitive distortions, and the development of a narrative of traumatic experiences. Phase 3 involves a resolution of dissociated self-state and a focus on current and future life issues.

- Treatment may be enhanced when therapists include continuous and frequent assessments of the therapeutic alliance and consider methods for enhancing it.
- Experts treating dissociative disorders advise only occasionally processing traumatic material. During the trauma-processing stage, experts frequently stabilize safety and augment trauma processing by using containment and grounding modalities.

ACUTE GENERAL Rx

Given the association between DDs and trauma, best practices suggest that a critical component of early treatment is the provision of a safe therapeutic environment. Identification of triggers associated with the onset of dissociation is useful. Controversy exists regarding the use of hypnosis for the purpose of recovering memories.

CHRONIC Rx

All stages of treatment may include psychoeducation, skill-building, alliance building, processing of reactions to therapy, emotion regulation, management of relationships, and stabilization. Grounding techniques, containment (i.e., imagery aimed at decreasing the intrusiveness of a memory), skill building (i.e., relaxation training and self-affirmation), and cognitive behavioral interventions (i.e., addressing irrational beliefs) are also used.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Research is lacking on complementary and alternative medicine for DDs.

DISPOSITION

Treatment should be delivered in the least restrictive environment possible to ensure patient safety. Patients who have comorbid psychiatric or medical diagnoses; who are experiencing suicidal or homicidal ideation, plans, or intention; or who are severely ill may require partial or inpatient hospitalization for the purpose of stabilization.

REFERRAL

Patients are treated by a mental health clinician.

PEARLS & CONSIDERATIONS

COMMENTS

- Diagnosis remains particularly challenging, as the features that present with this group of disorders (i.e., derealization, dissociation) are seen in many other psychiatric disorders (e.g., panic disorder, posttraumatic stress disorder [PTSD]). Incidence of dissociative symptoms following severe trauma is high. However, for most individuals, dissociative symptoms subside on their own within a few weeks following a traumatic event.
- Treatment approach may vary by the specific type of DD. Rigorous empirical studies assessing the treatment of specific DDs are lacking. For example, no randomized treatment studies have investigated the effectiveness of hypnosis in treating acute DA. Additionally, for chronic DA, pharmacologic facilitated intervention for the retrieval of memories (i.e., utilization of sodium pentobarbital or administration of intravenous lorazepam) is not well researched.

PREVENTION

Data are lacking on the prevention of DDs, but the prevention of child maltreatment may be useful in this regard.

Diverticular Disease (Diverticulosis, Diverticulitis, Diverticular Hemorrhage) ALG PTG

BASIC INFORMATION

DEFINITION

- Colonic diverticula are herniations of mucosa and submucosa (Figs. 1 and 2) through the muscularis. They are generally found along the colon's mesenteric border at the site where the vasa recta penetrates the muscle wall (anatomic weak point).
- *Diverticulosis* is the asymptomatic presence of multiple colonic diverticula.
- *Diverticulitis* is an inflammatory process or localized perforation of diverticulum.

ICD-10CM CODES

K57.30	Diverticulosis of large intestine without perforation or abscess without bleeding
K57.32	Diverticulitis of large intestine without perforation or abscess without bleeding
K57.31	Diverticulosis of large intestine without perforation or abscess with bleeding

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence of diverticulosis in the general population is 35% to 50%. Prevalence of diverticulosis increases with ages (<10% under age 40 to over 50% in those >85).
- Diverticulosis is more common in Western countries, affecting >30% of people >40 yr and >50% of people >70 yr.
- Approximately 20% of patients with diverticula have an episode of diverticulitis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination in patients with diverticulosis is generally normal.
- Painful diverticular disease can present with left lower quadrant (LLQ) pain, often relieved by defecation; location of pain may be anywhere in the lower abdomen because of the redundancy of the sigmoid colon.
- Diverticulitis can cause muscle spasm, guarding, and rebound tenderness predominantly affecting the LLQ. Factors associated with diverticulitis are pain localized to left lower quadrant and exacerbated by movement, left-lower-quadrant tenderness on examination, fever 38.5°C or higher, absence of vomiting, age >50 yr, and history of one or more episodes of diverticulitis.

ETIOLOGY

- Diverticular disease is believed to be secondary to low intake of dietary fiber.
- Recent studies indicate a pathogenetic role for inflammation in diverticulitis that may be similar to that of IBS, IBD, or both, based on common histologic findings such as granulomas, infiltrating lymphocytes, TNF, histamine, and matrix metalloproteinases.[1]

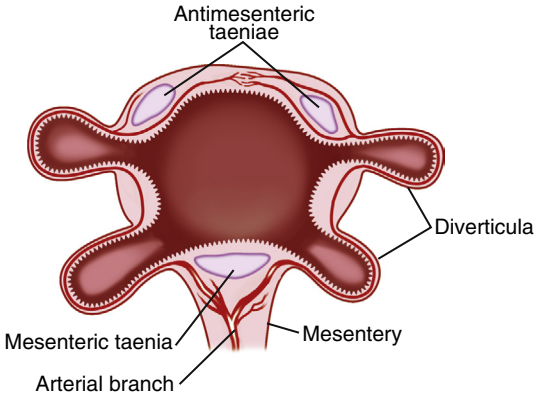

FIG. 1 Diagram showing colonic diverticula and their relationship to the taeniae coli. (From Feldman M et al [eds.]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

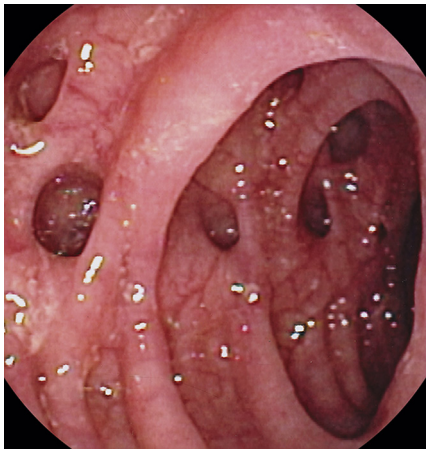

FIG. 2 Colonoscopic view of sigmoid diverticulosis. (From Feldman M et al [eds.]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- IBS
- IBD
- Colorectal cancer
- Endometriosis
- Ischemic colitis
- Bowel obstruction/volvulus
- Urinary tract disorders (urolithiasis, hydronephrosis)
- Infections (pseudomembranous colitis, appendicitis, pyelonephritis, PID)
- Lactose intolerance
- Celiac disease
- Epiploic appendagitis
- Gynecologic disorders (ectopic pregnancy, menstrual irregularities, dyspareunia, endometriosis)
- Cholecystitis, biliary disease

LABORATORY TESTS

- WBC count in diverticulitis reveals leukocytosis with left shift.
- Microcytic anemia can be present in patients with chronic bleeding from diverticular disease. MCV may be elevated in acute bleeding secondary to reticulocytosis.
- Urinalysis is useful to exclude urinary causes of pain.
- Pregnancy test is indicated in women of child-bearing age.
- Electrolytes and liver enzymes are useful in ruling out biliary causes of pain.
- CRP levels of 50 mg/L or greater is common in acute diverticulitis.

PROCEDURES: Colonoscopy should be avoided during acute diverticulitis due to the risk of perforation. It can generally be performed after 6 wk to rule out the presence of cancer and IBD.

IMAGING STUDIES

- If clinical features are highly suggestive of diverticulitis, imaging studies are generally not necessary.
- A CT scan of the abdomen (Fig. E3) with IV and luminal contrast is the preferred radiologic examination to diagnose acute diverticulitis. It can also diagnose diverticulosis.

[1]Morris AM et al: Sigmoid diverticulitis: a systematic review, *JAMA* 311(3):287-297, 2014.

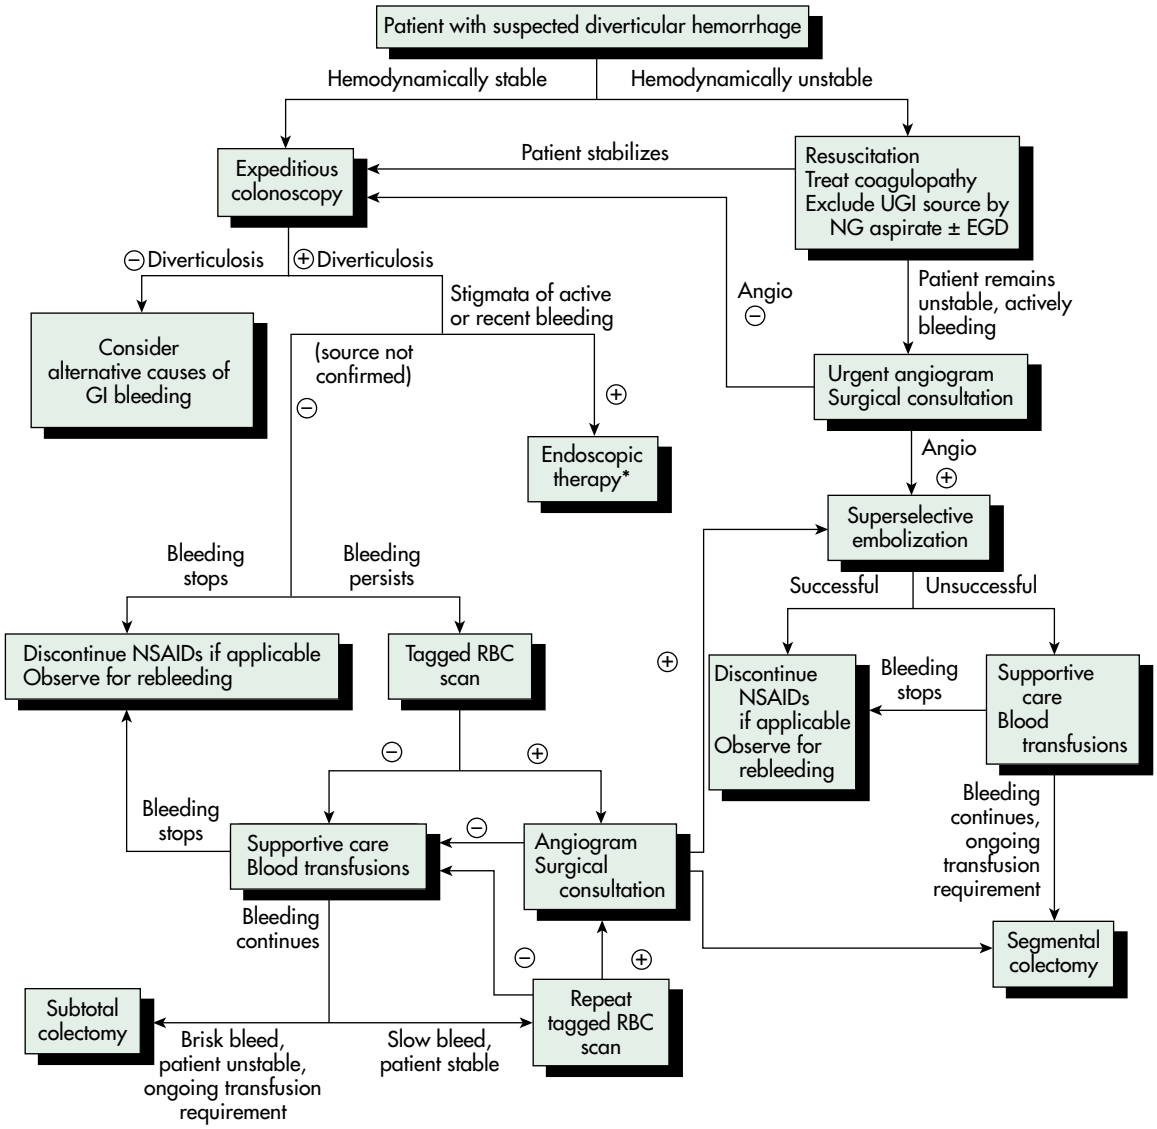

FIG. 4 Algorithm for the management of patients with suspected diverticular hemorrhage. *Angio*, Angiogram; *EGD*, esophagogastroduodenoscopy; *NG*, nasogastric; *NSAID*, nonsteroidal antiinflammatory drug; *RBC*, red blood cell; *UGI*, upper GI. *Endoscopic therapy may consist of epinephrine injection alone or in combination with other therapies, such as heater probe coagulation, bipolar coagulation, endoclips, fibrin sealant, and band ligation. (From Feldman M et al [eds.]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

It has a sensitivity of 93% to 97% and a specificity approaching 100% for diverticulitis. Typical findings are thickening of the bowel wall, fistulas, or abscess formation. CT may also reveal other disease processes (e.g., appendicitis, tubo ovarian abscess, Crohn disease) accounting for lower abdominal pain. In the Hinchey classification scheme based on CT results, stages 0 and Ia indicate uncomplicated diverticulitis, whereas stages Ib (pericolic or mesenteric abscess in proximity to the primary inflammatory process), II (intraabdominal abscess distant from primary inflammatory process or pelvic/retroperitoneal abscess), III (generalized purulent peritonitis), and IV (generalized fecal peritonitis) indicate complicated diverticulitis.

Ultrasonography and MRI can also be used. Abdominal ultrasonography has a 90% sensitivity and specificity for acute diverticulitis. MRI is also highly sensitive and specific for acute diverticulitis.

- Evaluation of suspected diverticular bleeding (Fig. 4):
  1. Arteriography if the bleeding is faster than 1 ml/min (advantage: The possible infusion of vasopressin directly into the arteries supplying the bleeding, as well as selective arterial embolization; disadvantages: Its cost and invasive nature)
  2. Technetium-99m sulfa colloid
  3. Technetium-99m labeled RBC (can detect bleeding rates as low as 0.12 to 5 ml/min)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Increase in dietary fiber intake and regular exercise to improve bowel function. However, recent studies have challenged the common view that fiber intake protects against diverticulosis.
- Oral diet of clear liquids is recommended until pain resolves in cases of mild uncomplicated diverticulitis.
- NPO and IV hydration in severe diverticulitis; NG suction if ileus or small bowel obstruction is present.
- Emergent surgery is required for perforation, peritonitis, or uncontrolled sepsis.

ACUTE GENERAL Rx

TREATMENT OF DIVERTICULITIS:

- Mild uncomplicated diverticulitis (75% of cases of diverticulitis): Broad-spectrum PO antibiotics (e.g., ciprofloxacin 750 mg bid or levofloxacin 750 mg bid or trimethoprim/sulfamethoxazole DS bid to cover aerobic component of colonic flora *and* metronidazole 500 mg q6h for anaerobes) and liquid diet for 7 to 10 days are commonly prescribed. Single-agent therapy with amoxicillin-clavulanic acid 875 mg/125 mg PO every 12 hours or moxifloxacin 400 mg PO every hour is also effective. Trials have shown no benefit of IV versus oral antibiotics and similar outcomes when using a 4-day course instead of a 7-day course of antibiotics. Other randomized trials and cohort studies have shown that antibiotics are not as beneficial or necessary as previously thought in cases of mild diverticulitis. Other modalities such as 5-aminosalicylate products and probiotics remain controversial and of unclear benefit.
- Mild to moderate complicated diverticulitis, in-patient treatment: Single-agent therapy with ertapenem 1 mg IV every 24 hours, ticarcillin-clavulanic acid 200 to 300 mg/kg per day divided doses every 6 hours, or moxifloxacin 400 mg IV every 24 hours for 4 to 7 days. Combination therapy of cefazolin (1 to 2 mg every 8 hours) or levofloxacin (750 mg every 24 hours) plus metronidazole (500 mg every 8 hours) is also effective.
- Severe complicated diverticulitis: NPO and aggressive IV antibiotic therapy
  1. Imipenem-cilastin 500 mg IV q6h *or*
  2. Piperacillin-tazobactam 4.5 g IV q8h *or*
  3. Meropenem 1 g IV q8h *or*
  4. Doripenem 500 mg IV q8h
  5. Cefepime 2 g IV q8h or ciprofloxacin 400 mg IV q12h each in combination with metronidazole 500 mg IV q8h
- Surgical treatment (laparoscopic preferred over open colectomy) consisting of resection of involved areas and reanastomosis (if feasible); otherwise, a diverting colostomy with reanastomosis is performed when infection has been controlled. The need for surgery as well as its optimal timing is unclear, and surgery is no longer considered necessary after a couple of episodes of diverticulitis. Surgery may be considered in patients with:
  1. Repeated episodes of diverticulitis
  2. Poor response to appropriate medical therapy (failure of conservative management)
  3. Abscess or fistula formation
  4. Obstruction
  5. Peritonitis: Colonic resection with a Hartmann pouch is the procedure of choice in critically ill patients with generalized peritonitis
  6. Immunocompromised patients, first episode in young patient (<40 yr old)
  7. Inability to exclude carcinoma (10% to 20% of patients diagnosed with diverticulosis on clinical grounds are subsequently found to have carcinoma of the colon)

DIVERTICULAR HEMORRHAGE:

- Bleeding is painless and stops spontaneously in the majority of patients (60%); it is usually caused by erosion of a blood vessel by a fecalith present within the diverticular sac.
- Medical therapy consists of blood replacement and correction of volume and any clotting abnormalities.
- Colonoscopic treatment with epinephrine injections, bipolar coagulation, or both may prevent recurrent bleeding and decrease the need for surgery. Endoclips (Fig. E5) can also be used to stop the bleeding.
- Surgical resection is necessary if bleeding does not stop spontaneously after administration of 4 to 5 U of PRBCs or recurs with severity within a few days; if attempts at localization are unsuccessful, total abdominal colectomy with ileoproctostomy may be indicated (high incidence of rebleeding if segmental resection is performed without adequate localization).

DISPOSITION

- The risk of recurrence among patients with uncomplicated diverticulitis is 32% to 36%. Most patients with diverticulitis respond well to antibiotic management and bowel rest. Up to 30% of patients with diverticulitis will eventually require surgical management.
- Diverticular bleeding can recur in 15% to 20% of patients within 5 yr.

REFERRAL

- GI referral for colonoscopy 4 to 6 wk after resolution of symptoms. In patients who have complications from diverticulitis, colonoscopy is generally not necessary after radiologically proven uncomplicated diverticulitis.
- Surgical referral when considering resection.

BASIC INFORMATION

DEFINITION

Down syndrome is a disorder characterized by mental retardation and multiple organ defects and is caused by a chromosomal abnormality (trisomy 21).

SYNONYMS

Trisomy 21
Mongolism

ICD-10CM CODE
Q90.9 Down syndrome, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 1 in 733 births
PEAK INCIDENCE: Newborn
PREVALENCE (IN U.S.): 300,000 persons
PREDOMINANT SEX: Male:female ratio of 1.3:1.0
PREDOMINANT AGE: Newborn to early adulthood
GENETICS: Nondisjunction causing trisomy 21

PHYSICAL FINDINGS & CLINICAL PRESENTATION

(Fig. E1)
- Microcephaly
- Flattening of occiput and face
- Upward slant to eyes with epicanthal folds
- Brushfield spots on iris
- Broad, stocky neck
- Small feet, hands, digits
- Single palmar crease

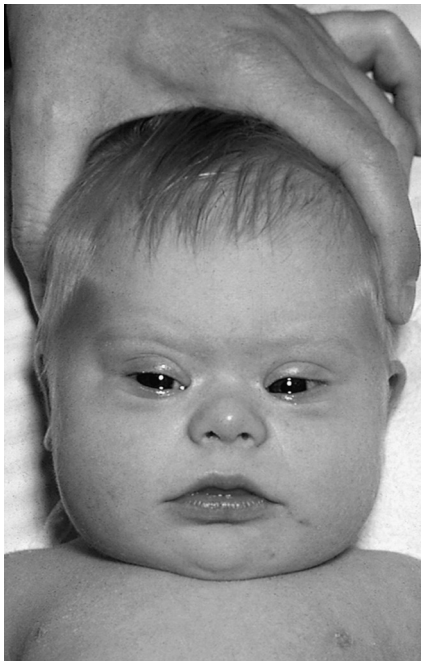

FIG. E1 Individual with Down syndrome. Note depressed nasal bridge, epicanthal folds, mongoloid slant of eyes, low-set ears, and large tongue. (From Zitelli BJ, Davis HW: *Atlas of pediatric physical diagnosis,* ed 3, St Louis, 1997, Mosby.)

- Hypotonia
- Short stature
- Clinical features of Down syndrome in the neonatal period are summarized in Table E1
- Associated with congenital heart disease, malformations of the GI tract, cataracts, hypothyroidism, hip dysplasia, obstructive sleep apnea, infantile spasms, Moyamoya disease, and myeloproliferative disorders
- About half of children with Down syndrome are born with congenital heart disease, with the most common lesions being atrial septal defect and ventricular septal defect
- Persistent primary congenital hypothyroidism is found in 1 in 141 newborns with Down syndrome compared with 1 in 4000 in the general population
- Ophthalmologic disorders increase in frequency with age; >80% of children ages 5 to 12 yr have disorders that need monitoring or intervention, such as refractive errors, strabismus, or cataracts
- Renal and urinary tract abnormalities
- Table E2 summarizes additional features of Down syndrome that can develop or become symptomatic with time

ETIOLOGY

Nondisjunction of chromosome 21

DIAGNOSIS

- The American College of Obstetrics and Gynecology recommends offering fetal chromosomal screening to all pregnant women regardless of age because of improvements in noninvasive screening methods. Cell-free DNA (CF DNA) testing for trisomy 21 has a higher sensitivity, a lower false positive rate, and a higher positive predictive value than standard screening with the measurement of nuchal translucency and biochemical analysis.[1]
- Combined use of serum screening and fetal ultrasound testing for thickened nuchal fold has 85% detection rate with 5% false-positive results. Second-trimester serum screening in combination with maternal age is improved with use of multiple serum markers.
- Prenatal cytogenic diagnosis by amniocentesis or chorionic villus sampling.
- Postnatal chromosomal karyotype.

DIFFERENTIAL DIAGNOSIS

- Congenital hypothyroidism
- Other chromosomal abnormalities

WORKUP

Postnatal chromosomal karyotype (Fig. E2)

TREATMENT

- Thyroid screen at birth, at age 6 mo, and yearly thereafter
- Echocardiogram in all newborns and cardiac assessment of adolescents for development of mitral valve prolapse
- Treatment consists of vigilant monitoring for comorbid states, such as obesity, hypothyroidism, leukemia, hearing loss, and valvular heart disease
- Prevention of obesity with low-calorie, high-fiber diet
- Auditory brain stem responses in all newborns and aggressive testing for hearing loss in children with chronic otitis media
- Ophthalmologic assessment by age 6 mo for congenital cataracts and annual examinations for monitoring of refractive errors and strabismus
- Regular dental care
- Pelvic examination of women who are sexually active or who have menstrual problems
- Dermatologic issues such as folliculitis can become problematic in adolescents and require topical antibiotics and careful attention to hygiene

DISPOSITION

Most children with Down syndrome live at home. As these individuals reach adulthood, those with higher functioning sometimes live in supervised settings away from their families.

REFERRAL

Down syndrome clinics use a preventive checklist to anticipate many clinical challenges.

PEARLS & CONSIDERATIONS

COMMENTS

- Screening for atlantoaxial subluxation is controversial.
- Most patients experience neuropathologic changes typical of Alzheimer disease. Presenting symptoms include seizures, focal neurologic signs, and apathy. If Alzheimer disease is suspected, screen for treatable diseases such as depression or hypothyroidism.
- This syndrome accounts for approximately one third of moderate to severe cases of mental retardation.
- Individuals with Down syndrome have a wide range of function, but all have a decrease in intelligence quotient (IQ) in the first decade of life.
- Deficiency of language production relative to other areas of development often causes substantial impairment.
- Although increased maternal age is a risk factor, most children with Down syndrome are born to women younger than age 35 yr.

TABLE E1 Clinical Features of Down Syndrome in the Neonatal Period

Central Nervous System
- Hypotonia*
- Developmental delay
- Poor Moro reflex*

Craniofacial
- Brachycephaly with flat occiput
- Flat face*
- Upward slanted palpebral fissures*
- Epicanthal folds
- Speckled irises (Brushfield spots)
- Three fontanels
- Delayed fontanel closure
- Frontal sinus and midfacial hypoplasia
- Mild microcephaly
- Short, hard palate
- Small nose, flat nasal bridge
- Protruding tongue, open mouth
- Small dysplastic ears*

Cardiovascular
- Endocardial Cushing defects
- Ventricular septal defect
- Atrial septal defect
- Patent ductus arteriosus
- Aberrant subclavian artery
- Pulmonary hypertension

Musculoskeletal
- Joint hyperflexibility*
- Short neck, redundant skin*
- Short metacarpals and phalanges
- Short 5th digit with clinodactyly*
- Single transverse palmar creases*
- Wide gap between 1st and 2nd toes
- Pelvic dysplasia*
- Short sternum
- Two sternal manubrium ossification centers

Gastrointestinal
- Duodenal atresia
- Annular pancreas
- Tracheoesophageal fistula
- Hirschsprung disease
- Imperforate anus
- Neonatal cholestasis

Cutaneous
- Cutis marmorata

*Hall's criteria to aid in diagnosis.

From Kliegman RM: *Nelson's textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

TABLE E2 Additional Features of Down Syndrome That Can Develop or Become Symptomatic with Time

Neuropsychiatric
- Developmental delay
- Seizures
- Autism spectrum disorders
- Behavioral disorders (disruptive)
- Depression
- Alzheimer disease

Sensory
- Congenital or acquired hearing loss
- Serous otitis media
- Refractive errors (myopia)
- Congenital or acquired cataracts
- Nystagmus
- Strabismus
- Glaucoma
- Blocked tear ducts

Cardiopulmonary
- Acquired mitral, tricuspid, or aortic valve regurgitation
- Endocarditis
- Obstructive sleep apnea

Musculoskeletal
- Atlantoaxial instability
- Hip dysplasia
- Slipped capital femoral epiphyses
- Avascular hip necrosis
- Recurrent joint dislocations (shoulder, knee, elbow, thumb)

Endocrine
- Congenital or acquired hypothyroidism
- Diabetes mellitus
- Infertility
- Obesity
- Hyperthyroidism

Hematologic
- Transient myeloproliferative syndrome
- Acute lymphocytic leukemia
- Acute myelogenous leukemia

Gastrointestinal
- Celiac disease
- Delayed tooth eruption
- Respiratory
- Obstructed sleep apnea
- Frequent infections (sinusitis, nasopharyngitis, pneumonia)

Cutaneous
- Hyperkeratosis
- Seborrhea
- Xerosis
- Perigenital folliculitis

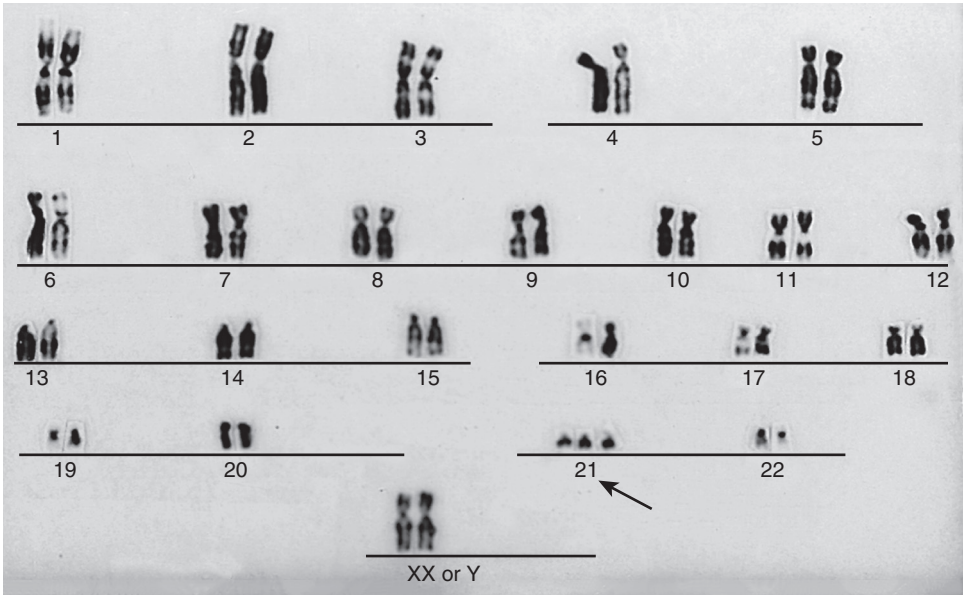

FIG. E2 Chromosomal karyotype showing trisomy (*arrow*).

BASIC INFORMATION

- Drowning aftereffects should be classified as death, morbidity, and absence of morbidity.
- The previously used terms *wet, dry, active, passive, silent,* and *secondary drowning* should no longer be used when considering statistical analysis; however, they remain in common use.

DEFINITION

Drowning is the process of experiencing respiratory impairment from submersion/immersion in liquid.

SYNONYMS

Suffocation
Asphyxiation

ICD-10CM CODES

W65	Accidental nontransport drowning and submersion
W67	Accidental drowning and submersion while in swimming pool
W69	Accidental drowning and submersion while in natural water
W74	Unspecified cause of accidental drowning and submersion

EPIDEMIOLOGY & DEMOGRAPHICS

- The fifth-leading cause of unintentional-injury death in the U.S.; 10 people die each day from drowning. Worldwide drowning accounts for more than 370,000 deaths/yr.
- Drowning is the most common injury-related cause of death in children 1 to 4 yr of age.
- Nearly 6000 persons are treated in U.S. emergency departments each yr for submersion or drowning injuries, with 50% of these patients requiring hospital admission.
- Between 2000 and 2007, the rate of fatal accidental drowning for African Americans was 130% that of whites; for Native Americans and Alaskan Natives, this rate was 170% that of whites.

INCIDENCE:

- From 2005 to 2014, an average of 3536 fatal unintentional drownings (nonboating related) occurred annually in the U.S. In California, Arizona, and Florida, drowning is the number one cause of injury-related death.
- Internationally the incidence is likely underestimated due to lack of reporting.

PEAK INCIDENCE:

- Ages 14 yr of age or younger account for 25%. High-risk groups are in the toddler age group and in young males. Fifteen percent of children admitted for drowning die in the hospital.
- Highest occurrence on weekends (~40%) in the summertime months (May through August), and more commonly in the rural southern and western U.S. (62%).

PREDOMINANT SEX & AGE:

- Males are 400% more likely to suffer a drowning due to increased risk-taking behavior.
- Age distribution is bimodal with the very young and elderly showing higher rates of submersion injury.

RISK FACTORS:

- Alcohol abuse
- Male
- Youth, elderly
- Seizure disorder
- Mental illness
- Cardiac disease
- Neuromuscular disorder, musculoskeletal disorder
- Frigid liquid temperature

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presentation varies; it most commonly is an unobserved individual found unconscious.
- Swimmers can suffer blackouts from hypocapnia when hyperventilating, and ascending divers may experience shallow water blackouts.
- A drowning classification system is used to classify victims at the rescue scene based on the following clinical parameters: Pulse, respirations, pulmonary auscultation, and blood pressure.

ETIOLOGY

- The primary factor is hypoxemia with subsequent multiorgan damage.
- The initiation of breath holding is complicated by laryngospasm if liquid is detected in the posterior pharynx/larynx, which impedes immediate inhalation. Once serum oxygen levels decrease, involuntary larynx relaxation occurs, and the victim aspirates liquid.
- If hypoxemia ensues and progresses to acidosis, myocardial ischemia and CNS ischemia are the predominant threats.
- A minority of drownings are considered "dry," with laryngospasm persisting until death.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Suicide
- Homicide
- Abuse
- Cranial/cervical trauma
- Seizure
- Cardiac arrhythmia
- Hypoglycemia

WORKUP

- Initiation of basic life support/advanced cardiac life support (BLS/ACLS)
- Cardiopulmonary monitoring
- Pulse oximetry
- ECG
- Assess for trauma
- Glasgow Coma Scale assessment

LABORATORY TESTS

- ABG
- Chemistry panel 7
- Toxicology screen
- Troponin
- Liver function tests
- Lactate
- Urinalysis

IMAGING STUDIES

- CXR for evaluation of pulmonary edema, aspiration, endotracheal tube placement, foreign body (Fig. E1)
- CT cervical/head for assessment of trauma and/or intracranial pathology

TREATMENT

- The foundation is management of basic cardiopulmonary functions of oxygenation, ventilation, respiration, and cardiac output (Table E1) as well as thermoregulation.
- An algorithm for drowning-severity classification and flow-chart strategy decision based on evaluation is described in Fig. E2.

NONPHARMACOLOGIC THERAPY

- Supplemental oxygen.
- CPAP or intubation with mechanical ventilation for respiratory failure.
- Permissive therapeutic hypothermia may benefit comatose patients.
- Extracorporeal membrane oxygenation is beneficial under specific circumstances.
- Bronchoscopy to remove foreign aspirated bodies.
- Treat secondary causes such as seizure, trauma, hypoglycemia.
- Table E2 summarizes which patients need further medical help after rescue from the water.

DISPOSITION

- Mental and cardiopulmonary status are core measures. Table E3 summarizes clinical prognostic scores for the immediate period after successful CPR based on the Glasgow coma score.
- ABG normalization.
- Correction of potential secondary etiologies.

REFERRAL

Once the patient is stabilized, transfer to a tertiary care facility is ideal with comatose patients or those requiring a specialist.

PEARLS & CONSIDERATIONS

- Early resuscitation is key.
- All guardians should have BLS training.

PREVENTION

Unattended access to bodies of water and poor rescue/safety training are key. Table E4 summarizes an approach to prevention strategies for drowning.

PATIENT & FAMILY EDUCATION

All guardians should have BLS training.

AUTHOR: **Kevin V. Plumley, MD, MPH**

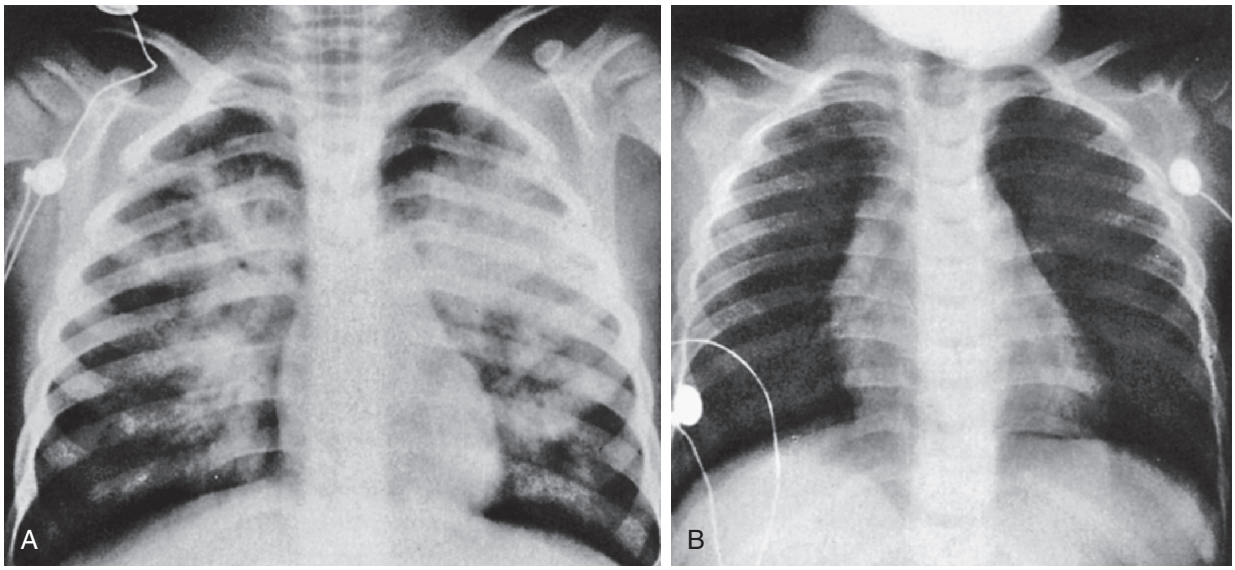

FIG. E1 Drowning with and without aspiration. Radiographs show a patient with severe pulmonary edema **(A)** and another without significant fluid aspiration **(B)**. (From Fuhrman BP, Zimmerman JJ: *Pediatric critical care*, ed 4, Philadelphia, 2011, Mosby.)

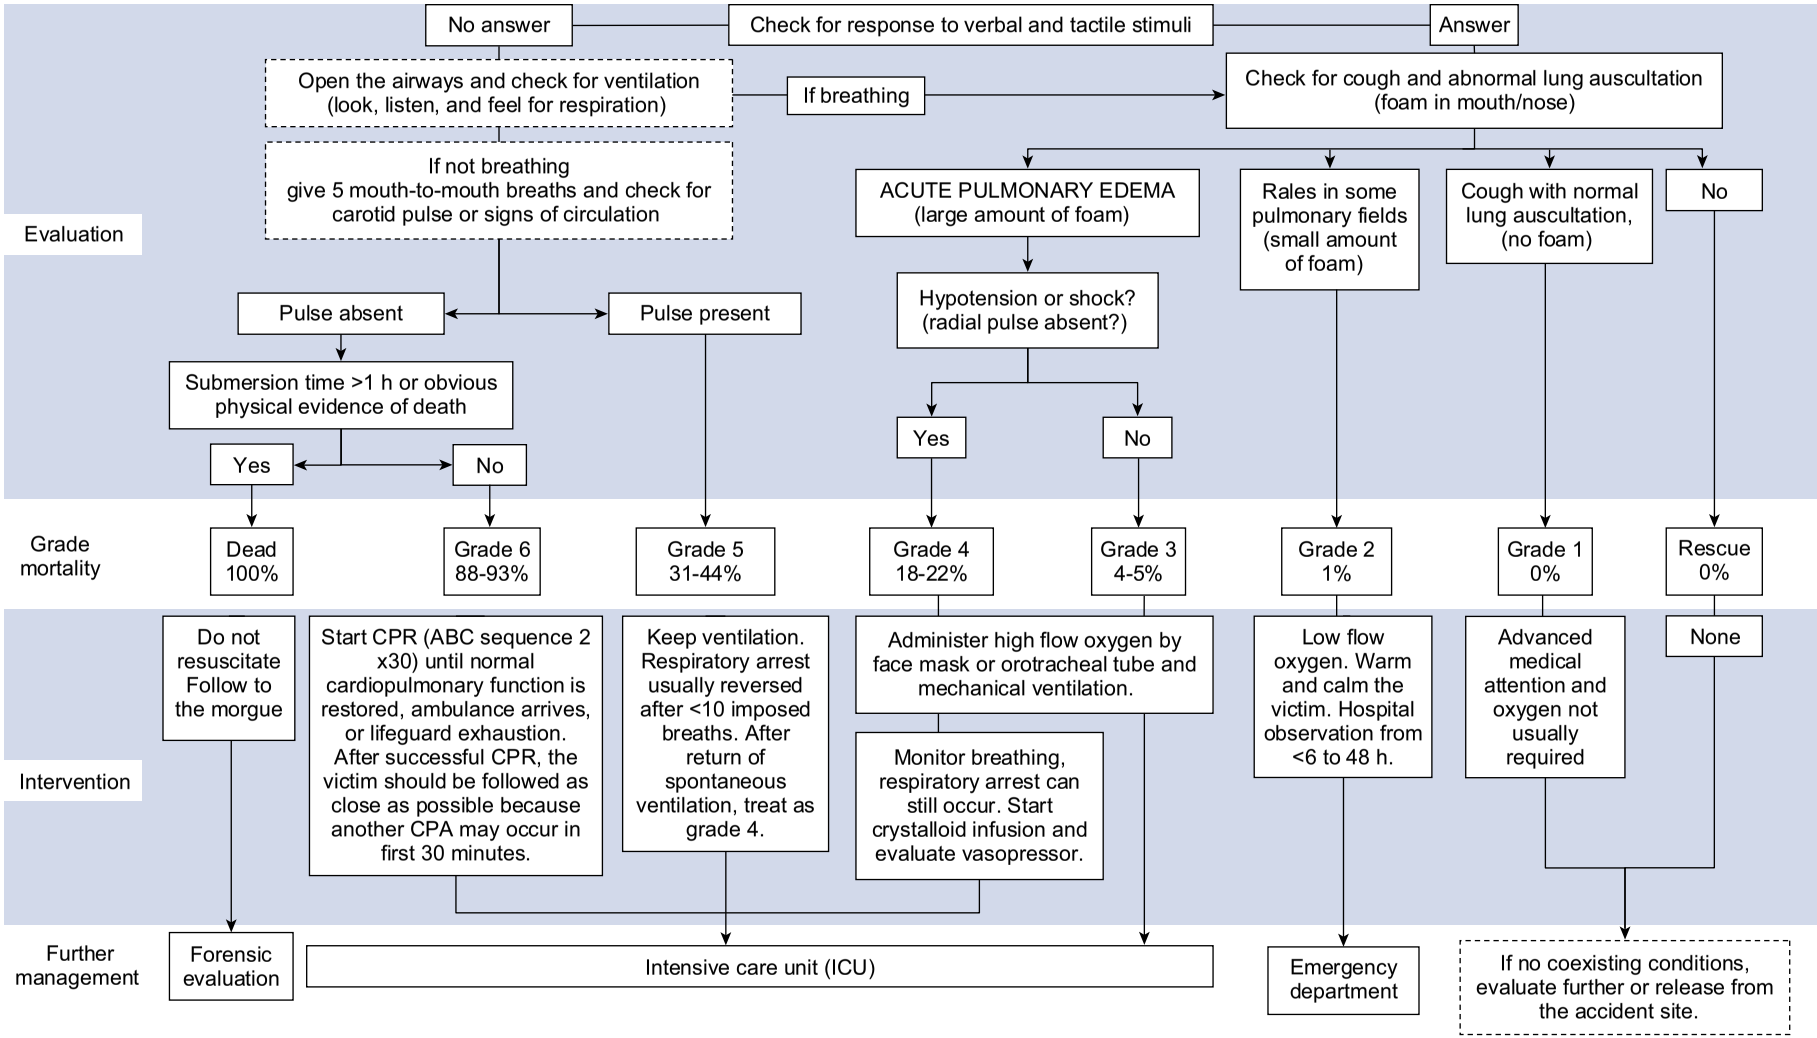
TABLE E1 Drowning: When to Initiate CPR and When to Discontinue

Question	Recommendations
In whom to begin?	Give ventilatory support for respiratory distress/arrest to avoid cardiac arrest. Start CPR in all submersions <60 min who do not present with obvious physical evidence of death.
When to discontinue?	Basic life support should continue unless signs of life reappear, rescuers are exhausted, or advanced life support can take over. Advanced life support should be ongoing until patient has been rewarmed (if hypothermic) and asystole persists for more than 20 min.

From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.



Abbreviations: CPR (cardiopulmonary resuscitation); CPA (cardiopulmonary arrest); recovery position (lateral decubitus position). Lay classification of severity terminology in bracket.

FIG. E2 Drowning severity classification and flow-chart strategy decision based on evaluation of 87,339 rescues. (From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.)

TABLE E2 Who Needs Further Medical Help after Rescue from the Water

(a) A patient who has experienced or required any of the following should be sent to a hospital:
   1. Loss of consciousness, even for a brief period
   2. Rescue breathing
   3. Cardiopulmonary resuscitation
   4. A serious condition such as heart attack, spinal injury, other injury, asthma, epilepsy, intoxication, or delirium

(b) The following persons may be considered for release from care at the scene if—after 10 to 15 min of careful observation while being warmed with blankets or other coverings as required—the patient meets *all* of the following criteria:
   1. No cough
   2. Normal rate of breathing
   3. Normal circulation as measured by pulse in strength, rate, and blood pressure (if available)
   4. Normal color and skin perfusion
   5. No shivering
   6. Is fully conscious, awake, and alert

   In such cases, it is unwise for the patient to drive a vehicle, and the patient should be so advised. If any of these conditions does not apply or if the lifesaver has any doubt, the patient should be advised to seek early medical attention

(c) There is always a risk of delayed lung complications. All immersion victims should therefore be warned that if they later develop cough, breathlessness, fever, or any other concerning respiratory symptoms, they should seek medical advice immediately. It is preferable that these persons not return to a home environment where they are alone for the next 24 hours

From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.

TABLE E3 Clinical Prognostic Score for the Immediate Period after Successful CPR Based on Glasgow Coma Score

Neurologic Prognostic Score after Successful CPR upon Drowning	
A: First hr	**B: After 5-8 hr**
Alert, 10	Alert, 9.5
Confused, 9	Confused, 8
Torpor, 7	Torpor, 6
Coma with normal brain stem functions, 5	Coma with normal brain stem functions, 3
Coma with abnormal brain stem functions, 2	Coma with abnormal brain stem functions, 1
A + B	
Recovery without Sequelae	
Excellent, ≥13	≥95%
Very good, 10-12	75%-85%
Good, 8	40%-60%
Regular, 5	10%-30%
Poor, 3	≤5%

CPR, Cardiopulmonary resuscitation.

From Orlowski JP, Szpilman D: Drowning—Rescue, resuscitation, and reanimation. In *Pediatric critical care: A new millennium*, Vol. 48, 2001, W. B. Saunders Company, Pediatric Clinics of North America, pp 627–646.

From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.

TABLE E4 Approach to Prevention Strategies for Drowning

	Home	Recreation	Neighborhood
Water hazards	Swimming pools Ponds Bathtubs Large buckets	Playing in water: Swimming, wading Playing near water Being on water: Boating	Irrigation ditches Watering holes Water drainage
Common risks	Lapse in supervision Unexpected toddler exposure Delayed discovery of child Reliance on water wings or pool toys Reliance on sibling or bath seat for bathing supervision	Lapse in supervision Change in weather Unfamiliarity with or change(s) in water conditions: Steep drop-off Current/tide Low temperature Alcohol use Peer pressure	Lapse in supervision, particularly when caregiver is socializing Risky behavior when with peers
Prevention strategies	Recognize hazards and risks. Provide constant adult supervision around water. Install 4-sided, isolation fencing around pools. Install rescue equipment and phone at poolside. Learn swimming and water survival skills. Avoid bath; instead shower, if a child/teen with seizure disorder. Learn first aid and CPR.	Provide constant adult supervision. Swim in lifeguarded areas. Know when and how to wear U.S. Coast Guard–approved PFDs. Avoid alcohol and other drugs. Learn swimming and water survival skills. Teach children about water safety. Be aware of current weather and water conditions. Learn first aid and CPR.	Identify hazardous bodies of water. Prevent access to water with the use of barriers. Provide fenced-in "safe area" for water recreation. Provide lifeguarded swim sites. Provide access to low-cost swim/water survival lessons.

CPR, Cardiopulmonary resuscitation; *PFDs*, personal flotation devices.

Drug-Induced Liver Injury

BASIC INFORMATION

DEFINITION

Drug-induced liver injury (DILI) is defined as any injury to the liver by any medication such as a prescription medication, an over-the-counter medication, or an herbal/dietary supplement. It can present as asymptomatic liver test elevations or as acute liver failure.

SYNONYMS

Toxic liver disease
DILI

ICD-10CM CODES

K71.0	Toxic liver disease with cholestasis
K71.1	Toxic liver disease with hepatic necrosis
K71.10	Toxic liver disease with hepatic necrosis without coma
K71.11	Toxic liver disease with hepatic necrosis with coma
K71.2	Toxic liver disease with acute hepatitis
K71.3	Toxic liver disease with chronic persistent hepatitis
K71.4	Toxic liver disease with chronic lobular hepatitis
K71.5	Toxic liver disease with chronic active hepatitis
K71.50	Toxic liver disease with chronic active hepatitis without ascites
K71.51	Toxic liver disease with chronic active hepatitis with ascites
K71.6	Toxic liver disease with hepatitis, not elsewhere classified
K71.7	Toxic liver disease with hepatitis with fibrosis and cirrhosis of the liver
K71.8	Toxic liver disease with hepatitis, not elsewhere classified
K71.8	Toxic liver disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Estimated annual incidence between 10 and 15 per 10,000 to 100,000 has been reported.

PEAK INCIDENCE: N/A
PREVALENCE: N/A
PREDOMINANT SEX AND AGE: Incidence increases with age and is more common in females.
RISK FACTORS:

- Predisposing factors: Female gender, race, and older age.
- Acquired risk factors: Chronic alcohol use, extrahepatic disease (i.e., hyperthyroidism, HIV, etc.).
- A patient's nutritional status can influence their ability to metabolize medications.

GENETICS: Genetic polymorphisms can lead to altered expressions of various liver cytochrome p450 enzymes. Table E1 summarizes factors influencing the risk of liver diseases caused by drugs.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The physical findings and presentation depend on the classification of hepatic injury incited by the drug.
- These are usually divided into hepatocellular, cholestatic, or a mixed picture of hepatocellular and cholestatic injury. Table E2 describes a clinicopathologic classification of drug-induced liver disease.
- Some patients are asymptomatic, and DILI is detected only because of abnormal labs.
- Symptomatic patients present with fever, nausea, vomiting, malaise, anorexia, right upper quadrant pain, jaundice, acholic stools, or dark urine.
- Patients may also present with pruritus and hepatomegaly on physical examination.
- Patients may have muscular symptoms such as myalgia, stiffness, weakness, and elevated creatinine kinase level.

ETIOLOGY

- Drug-induced liver injury can result due to toxicity of over-the-counter drugs, prescription medications, anesthetics (Table E3), or herbal remedies/supplements (Table E4). The clinicopathologic spectrum of chemical hepatotoxins is summarized in Box E1.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hepatitis (Tables E5 and E6): Viral hepatitis, alcoholic liver disease, nonalcoholic fatty liver disease, autoimmune hepatitis, and Wilson disease
- Cholestasis: Biliary obstruction, primary biliary cirrhosis, primary sclerosing cholangitis, and intrahepatic cholestasis of pregnancy
- Steatosis: Nonalcoholic fatty liver disease, nonalcoholic steatohepatitis, and acute fatty liver of pregnancy
- Granulomatous hepatitis (Table E7): Sarcoidosis, infection, and primary biliary cirrhosis
- Peliosis hepatitis: Infections, hematologic disorders, and organ transplantation

WORKUP

- A thorough history and blood tests to evaluate other possible causes of hepatic injury help make the diagnosis
- Liver function tests
- Hepatitis A, B, and C serologies, antinuclear antibody, anti-smooth muscle antibody, anti-liver kidney microsomal antibody, alpha 1 antitrypsin, ceruloplasmin, fasting glucose, triglycerides, and hemoglobin A1c

LABORATORY TESTS

- Hepatocellular findings:
  1. Abnormal elevations in serum aminotransferases when compared to alkaline phosphatase (ALP)
  2. Alanine aminotransferase (ALT)/ALP ratio greater than 5
- Cholestatic findings:
  1. Abnormal elevations in the alkaline phosphatase compared to the serum aminotransferases
  2. ALP >2 times the upper limit of normal and/or ALT to ALP ratio <2
- Mixed hepatocellular/cholestatic findings:
  1. ALT/ALP ratio >2 but <5
- In either of these types of DILI, the serum bilirubin may or may not be elevated.

TABLE E1 Factors Influencing the Risk of Liver Diseases Caused by Drugs

Factor	Examples of Drugs Affected	Influence
Genetic factors	Halothane, phenytoin, sulfonamides	Multiple cases in families
	Amoxicillin-clavulanic acid, flucloxacillin, abacavir	Strong HLA association
	Valproic acid	Familial cases; association with mitochondrial enzyme deficiencies
Age	Isoniazid, nitrofurantoin, halothane, troglitazone	Age >60 yr; increased frequency, increased severity
	Valproic acid, salicylates	More common in children
Gender	Halothane, minocycline, nitrofurantoin	More common in women, especially in cases with chronic hepatitis
	Amoxicillin-clavulanic acid, azathioprine	More common in men
Dose	Acetaminophen, aspirin, some herbal medicines	Blood levels are directly related to the risk of hepatotoxicity
	Tetracycline, tacrine, oxypenicillins	Idiosyncratic reactions, with partial relationship to dose
	Methotrexate, vitamin A	Total dose, dosing frequency, and duration of exposure are related to the risk of hepatic fibrosis
Other drugs	Acetaminophen	Isoniazid, zidovudine, and phenytoin lower the dose threshold and increase the severity of hepatotoxicity

Continued

TABLE E1 Factors Influencing the Risk of Liver Diseases Caused by Drugs—cont'd

Factor	Examples of Drugs Affected	Influence
	Valproic acid	Other antiepileptic drugs increase the risk of hepatotoxicity
	Anticancer drugs	Interactive vascular toxicity
History of other drug reactions	Isoflurane, halothane, enflurane Erythromycins Diclofenac, ibuprofen, tiaprofenic acid Sulfonamides, COX-2 inhibitors	Instances of cross-sensitivity have been reported among members of each drug class but are rare
Excessive alcohol use	Acetaminophen	Lowered dose threshold, poorer outcome
	Isoniazid, methotrexate	Increased risk of liver injury, hepatic fibrosis
Nutritional Status:		
Obesity	Halothane, troglitazone, tamoxifen, methotrexate	Increased risk of liver injury, hepatic fibrosis
Fasting	Acetaminophen	Increased risk of hepatotoxicity
Preexisting liver disease	Hycanthone, pemoline	Increased risk of liver injury
	Antituberculosis drugs, ibuprofen	Increased risk of liver injury with chronic hepatitis B and C
Other Diseases/Conditions:		
Diabetes mellitus	Methotrexate	Increased risk of hepatic fibrosis
HIV/AIDS	Sulfonamides	Increased risk of hypersensitivity
Renal failure	Tetracycline, methotrexate	Increased risk of liver injury, hepatic fibrosis
Organ transplantation	Azathioprine, thioguanine, busulfan	Increased risk of vascular toxicity

AIDS, Acquired immunodeficiency syndrome; *COX-2,* cyclooxygenase-2; *HIV,* human immunodeficiency virus; *HLA,* human leukocyte antigen.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E2 Clinicopathologic Classification of Drug-Induced Liver Disease

Category	Description	Implicated Drugs: Examples
Hepatic adaptation	No symptoms; raised serum GGTP and AP levels (occasionally raised ALT)	Phenytoin, warfarin, heparins
	Hyperbilirubinemia	Rifampin, HIV protease inhibitors
Dose-dependent hepatotoxicity	Symptoms of hepatitis; zonal, bridging, and massive necrosis; serum ALT level >5-fold increased, often >2000 U/L	Acetaminophen, nicotinic acid, amodiaquine, hycanthone
Other cytopathic toxicity, acute steatosis	Microvesicular steatosis, diffuse or zonal; partially dose dependent, severe liver injury, features of mitochondrial toxicity (lactic acidosis)	Valproic acid, didanosine, HAART agents, fialuridine, L-asparaginase, some herbal medicines
Acute hepatitis	Symptoms of hepatitis, focal, bridging, and massive necrosis; serum ALT level >5-fold increased; extrahepatic features of drug allergy in some cases	Isoniazid, dantrolene, nitrofurantoin, halothane, sulfonamides, phenytoin, disulfiram, acebutolol, etretinate, ketoconazole, terbinafine, troglitazone
Chronic hepatitis	Duration >3 mo; interface hepatitis, bridging necrosis, fibrosis, cirrhosis; clinical and laboratory features of chronic liver disease; autoantibodies with some types of reaction	Nitrofurantoin, etretinate, diclofenac, minocycline, nefazodone
Granulomatous hepatitis	Hepatic granulomas with varying hepatitis and cholestasis; raised serum ALT, AP, GGTP levels	Allopurinol, carbamazepine, hydralazine, quinidine, quinine
Cholestasis without hepatitis	Cholestasis, no inflammation; serum AP levels > twice normal	Oral contraceptives, androgens
Cholestatic hepatitis	Cholestasis with inflammation; symptoms of hepatitis; raised -serum ALT and AP levels	Chlorpromazine, tricyclic antidepressants, erythromycins, amoxicillin–clavulanic acid, cyproterone acetate
Cholestasis with bile duct injury	Bile duct lesions and cholestatic hepatitis; clinical features of cholangitis	Chlorpromazine, flucloxacillin, dextropropoxyphene
Chronic cholestasis	Duration >3 mo	
Vanishing bile duct syndrome (VBDS)	Paucity of small bile ducts; resembles PBC but AMA negative	Chlorpromazine, flucloxacillin, trimethoprim/sulfamethoxazole
Sclerosing cholangitis	Strictures of large bile ducts	Intraarterial floxuridine, intralesional scolicidals
Steatohepatitis	Steatosis, focal necrosis, Mallory hyaline, pericellular fibrosis, cirrhosis; chronic liver disease, portal hypertension	Perhexiline, amiodarone, tamoxifen
Fibrosis and cirrhosis	Fibrosis, nodular regeneration (other features [e.g., interface hepatitis, steatohepatitis, paucity of bile ducts, cholestasis] depend on etiology)	Methotrexate, cyproterone acetate; also see VBDS, chronic hepatitis, steatohepatitis
Vascular disorders	Sinusoidal obstruction syndrome, nodular regenerative hyperplasia, others	Many
Tumors	Hepatocellular carcinoma, adenoma, angiosarcoma, others	Many

ALT, Alanine aminotransferase; *AMA,* antimitochondrial antibody; *AP,* alkaline phosphatase; *GGTP*, gamma-glutamyl transpeptidase; *HAART*, highly active antiretroviral therapy; *HIV,* human immunodeficiency virus; *PBC,* primary biliary cirrhosis.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E3 Comparative Features of Causes of Acute Postoperative Liver Injury

Feature	Haloalkane Anesthetic Toxicity	Ischemic Hepatitis	Postoperative Cholestasis
Incidence	Rare	Not uncommon	Common
Latency	2-15 days	Within 24 hours	A few days
Fever, rash, eosinophilia	Present	Absent	Absent
Serum ALT/AST (×ULN)	25-200×	Can exceed 200× (AST≫ALT)	Minimal or normal
Jaundice	Common	Rare	Common (direct hyperbilirubinemia)
Histology	Zone 3 necrosis	Coagulative necrosis, sinusoidal congestion	Bile plugs, cholestasis
Mortality	High	Varies with diagnosis	Not from liver disease
Recovery time	Up to 12 wk	10-12 days with supportive care	Variable, may be prolonged
Risk Factors			
Age	Adults, age >40 yr	Any	Any
Gender	F > M 2:1	F = M	F = M
Body weight	Obese	Any	Any
Hypotension	May or may not be present	Documented in 50%	Absent

ALT, Alanine aminotransferase; *AST,* aspartate aminotransferase; *F*, Female; *M*, male; *ULN*, upper limit of normal.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E4 Hepatotoxic Herbal Remedies, Dietary Supplements, and Weight Loss Products

Remedy	Popular Uses	Source	Hepatotoxic Component	Type of Liver Injury
Ayurvedic herbal medicine	Multiple	Multiple	Uncertain (may contain heavy metal contaminants)	Hepatitis
Barakol	Anxiolytic	*Cassia siamea*	Uncertain	Reversible hepatitis or cholestasis
Black cohosh	Menopausal symptoms	*Cimicifuga racemosa*	Uncertain	Hepatitis (causality uncertain)
"Bush tea"	Fever	*Senecio, Heliotropium, Crotalaria* spp.	Pyrrolizidine alkaloids	SOS
Cascara	Laxative	*Cascara sagrada*	Anthracene glycoside	Cholestatic hepatitis
Chaparral leaf (greasewood, creosote bush)	"Liver tonic," burn salve, weight loss	*Larrea tridentate*	Nordihydroguaiaretic acid	Acute and chronic hepatitis, FHF
Chaso/onshido	Weight loss	—	*N*-nitro-fenfluramine	Acute hepatitis, FHF
Chinese medicines (traditional)				
Jin bu huan	Sleep aid, analgesic	*Lycopodium serratum*	Levo-tetrahydropalmatine	Acute or chronic hepatitis or cholestasis, steatosis
Ma huang	Weight loss	*Ephedra* spp.	Ephedrine	Severe hepatitis, FHF
Shou-wu-pian	Anti-aging, neuroprotection, laxative	*Polygonum multiflorum* Thumb (fleeceflower root)	Anthraquinone	Acute hepatitis or cholestasis
Sho-saido-to	Multiple	*Scutellaria* root	Diterpenoids	Hepatocellular necrosis, cholestasis, steatosis, granulomas
Comfrey	Herbal tea	*Symphytum* spp.	Pyrrolizidine alkaloid	Acute SOS, cirrhosis
Germander	Weight loss, fever	*Teucrium chamaedrys, T. capitatum, T. polium*	Diterpenoids, epoxides	Acute and chronic hepatitis, FHF, autoimmune injury
Greater celandine	Gallstones, IBS	*Chelidonium majus*	Isoquinoline alkaloids	Cholestatic hepatitis, fibrosis
Green tea leaf extract	Multiple	*Camellia sinensis*	Catechins	Hepatitis (causality questioned)
Herbalife	Nutritional supplement, weight loss	—	Various; ephedra	Severe hepatitis, FHF
Hydroxycut	Weight loss	*Camellia sinensis*, among other constituents	Uncertain	Acute hepatitis, FHF
Impila	Multiple	*Callilepis laureola*	Potassium atractylate	Hepatic necrosis
Kava	Anxiolytic	*Piper methysticum*	Kava lactone, pipermethystine	Acute hepatitis, cholestasis, FHF
Kombucha	Weight loss	Lichen alkaloid	Usnic acid	Acute hepatitis
Limbrel (Flavocoxid)	Osteoarthritis	Plant bioflavonoids	Baicalin, epicatechin	Acute mixed hepatocellular-cholestatic injury
LipoKinetix	Weight loss	Lichen alkaloid	Usnic acid	Acute hepatitis, jaundice, FHF

Continued

TABLE E4 Hepatotoxic Herbal Remedies, Dietary Supplements, and Weight Loss Products—cont'd

Remedy	Popular Uses	Source	Hepatotoxic Component	Type of Liver Injury
Mistletoe	Asthma, infertility	*Viscus album*	Uncertain	Hepatitis (in combination with skullcap)
Oil of cloves	Dental pain	Various foods, oils	Eugenol	Zonal necrosis
Pennyroyal (squaw mint oil)	Abortifacient	*Hedeoma pulegioides, Mentha pulegium*	Pulegone, monoterpenes	Severe hepatocellular necrosis
Prostata	Prostatism	Multiple	Uncertain	Chronic cholestasis
Sassafras	Herbal tea	*Sassafras albidum*	Safrole	HCC (in animals)
Senna	Laxative	*Cassia angustifolia*	Sennoside alkaloids; anthrone	Acute hepatitis
Skullcap	Anxiolytic	*Scutellaria*	Diterpenoids	Hepatitis
Valerian	Sedative	*Valeriana officinalis*	Uncertain	Elevated liver enzymes

FHF, Fulminant hepatic failure; *HCC,* hepatocellular carcinoma; *IBS*, irritable bowel syndrome; *SOS,* sinusoidal obstruction syndrome.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

BOX E1 Clinicopathologic Spectrum of Chemical Hepatotoxins

Acute Injury
Necrosis
Carbon tetrachloride and other haloalkanes
Cocaine, "ecstasy," phencyclidine
Haloaromatics, nitroaromatics, nitroaliphatics
Hydrochlorofluorocarbons
Phosphorus, iron, copper salts, inorganic arsenic

Microvesicular Steatosis
Boric acid
Chlordecone
Cocaine
Dimethylformamide
Hydrazine
Hypoglycin
Thallium
Toluene, xylene

Cholestasis
Alpha-naphthylisocyanate
Aniline—rapeseed oil
Dinitrophenol
Methylenedianiline
Paraquat

Subacute Injury
Necrosis
Trinitrotoluene

Sinusoidal Obstruction Syndrome
Pyrrolizidine alkaloids, arsenic, thorium dioxide

Toxic Cirrhosis
Hexachlorobenzene, polychlorinated biphenyls
Tetrachloroethane

Peliosis Hepatis
Dioxin

Chronic Injury
Cirrhosis
Chlor aliphatics, trinitrotoluene, arsenic, pyrrolizidine alkaloids

Hepatoportal Sclerosis
Arsenic, vinyl chloride

Neoplasia
Hepatocellular Carcinoma
Arsenic, aflatoxins, thorium dioxide

Angiosarcoma
Vinyl chloride, thorium dioxide, arsenic

Hemangioendothelioma
Arsenic

From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TABLE E5 Drug-Induced Chronic Hepatitis: Causative Agents, Risk Factors, Clinicopathologic Features, and Outcomes

Causative Agent*	Risk Factors	Clinicopathologic Features	Outcomes
Nitrofurantoin	Age >40 yr; 90% of cases in women; continued ingestion after onset	Clinical features of chronic hepatitis, liver failure; some cases with features of cholestasis; 20% with pneumonitis; hyperglobulinemia usual, ANA, SMA	Mortality rate 10%
Methyldopa	Age >50 yr; 80% of cases in women; repeated courses, continued ingestion in sensitized patient	Jaundice, diarrhea, liver failure; hyperglobulinemia, ANA, SMA positive; protracted course	High mortality rate
Diclofenac	Age >65 yr; most cases in women	Clinical features of chronic hepatitis, liver failure; hyperglobulinemia, ANAs, SMA	Response to glucocorticoids in a few cases
Minocycline	Young women; prolonged use of drug	Often part of drug-induced systemic lupus erythematosus syndrome (arthritis, rash, rarely nephritis); hyperglobulinemia, ANAs	Cases may be severe, with a fatal outcome or need for liver transplantation; glucocorticoid treatment may be indicated
Isoniazid	Age >50 yr; continued drug ingestion after onset; duration of therapy	Severe and fatal cases with cirrhosis; no immune phenomena	High mortality rate or need for liver transplantation
Dantrolene	Age >30 yr; dose, duration of therapy	Jaundice, liver failure; no immune phenomena	High mortality rate
Etretinate	Age >50 yr; two-thirds in women	Jaundice, weight loss, liver failure; deterioration after stopping drug	Response to glucocorticoids in two reported cases
Acetaminophen	Regular intake at moderate doses (2-6 g/day); alcohol, fasting, other drugs	No features of chronic liver disease, no autoimmune phenomena; these are cases of chronic toxicity	Rapid normalization of liver biochemical test levels after the drug is stopped

*Several other agents, including sulfonamides, aspirin, halothane, cimetidine, methotrexate, trazodone, fluoxetine, fenofibrate, and germander, have been mentioned as associated with chronic hepatitis, but evidence of causation is not robust. In the past, causes included oxyphenisatin and tienilic acid, which are no longer available.
ANA, Antinuclear antibody; *SMA*, smooth muscle antibody.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E6 Drug-Induced Acute Hepatitis: Immunoallergic Reaction vs. Metabolic Idiosyncrasy

Characteristic	Immunoallergic Reaction	Metabolic Idiosyncrasy
Frequency	<1 case per 10,000 persons exposed	1-50 cases per 10,000 persons exposed
Gender predilection	Women, often ≥2:1	Variable, slightly more common in women
Latent period to onset of hepatitis	Fairly constant, 2-10 wk	More variable, 2-24 wk, occasionally >1 yr
Relationship to the dose	None	Usually none, but drugs with daily doses >50 mg/day are overrepresented in cases of DILI
Interactions with other agents	None	Alcohol; occasionally other drugs (e.g., isoniazid with rifampin)
Course after stopping the drug	Prompt improvement (rare exceptions [e.g., minocycline])	Variable; occasionally slow improvement or deterioration (e.g., troglitazone)
Positive rechallenge	Always; often fever within 3 days	Usual (in two thirds of cases), abnormal liver biochemical test levels in 2-21 days
Fever	Usual; often initial symptom, part of prodrome	Infrequent, less prominent
Extrahepatic features (rash, lymphadenopathy)	Common	Rare
Eosinophilia		
Blood	33%-67% of cases	<10% of cases
Tissue	Usual, pronounced	Common but mild
Autoantibodies	Often present	Rarely present
Examples	Nitrofurantoin, phenytoin, methyldopa, sulfonamides, etretinate, minocycline	Isoniazid, pyrazinamide, ketoconazole, dantrolene, troglitazone

DILI, Drug-induced liver injury.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E7 Drug-Induced Granulomatous Hepatitis: Major Causative Agents, Frequency, Risk Factors, Clinicopathologic Features, and Outcomes

Causative Agent*	Frequency	Risk Factors	Clinicopathologic Features	Outcomes
Carbamazepine	16:100,000 treatment-yr	Age >40 yr, no gender predilection	Two thirds of cases show granulomatous hepatitis; the remainder show acute hepatitis, cholangitis; no features of drug allergy	No reported fatality, rapid recovery
Phenylbutazone	1:5000 exposed	No age or gender predilection	Severe acute hepatitis, cholestasis, and bile duct injury are also reported; features of drug allergy are common; occasionally vasculitis	Mortality rate 25%, particularly in cases with hepatocellular necrosis
Allopurinol	Rare (<40 cases)	Older men, black race, renal failure, use of thiazides	Acute hepatitis, cholestatic hepatitis, bile duct injury are also frequent; rash (exfoliative dermatitis), nephritis, vasculitis are usual	Mortality rate 15%, especially with vasculitis
Hydralazine	Rare	Older patients, possibly slow acetylators	Other types of reaction are also common: Acute hepatitis, cholestatic hepatitis, cholangitis; features of drug allergy are uncommon; vasculitis is not described	Reactions severe, but no mortality reported
Quinine	Rare	No recognized risk factors	Acute hepatitis occurs in two thirds of cases; rash, interstitial pneumonitis, positive Coombs test, thrombocytopenia	Good prognosis

*Other drugs that have been reliably reported to cause granulomatous hepatitis include quinidine, phenytoin (usually with vasculitis), sulfonamides (usually with vasculitis), nitrofurantoin, aspirin, papaverine, procainamide, sulfasalazine, mesalamine, and glyburide. Single-case reports have implicated many other agents, as referred to briefly in the text.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

IMAGING STUDIES

- Imaging studies such as right upper quadrant ultrasound or magnetic resonance cholangiopancreatography (MRCP) to rule out biliary obstruction may be needed if there is evidence of cholestasis.
- Typically there is no need to do a liver biopsy unless the diagnosis is uncertain.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Avoiding certain drugs and herbal supplements with underlying liver disease is very important.

ACUTE GENERAL Rx

- The mainstay of treatment is to avoid the offending agent.
- N-acetylcysteine is used for acetaminophen toxicity.
- L-carnitine is used for valproic acid toxicity.
- Glucocorticoids do not have proven benefit but are sometimes given for hypersensitivity reactions of the liver in which there is progressive cholestasis or in which biopsy reveals features similar to that of autoimmune hepatitis.
- For patients who present with pruritus in the setting of cholestatic liver disease, a bile acid sequestrant can be given.

CHRONIC Rx

There is insufficient evidence to support the use of any medication, vitamin, or nutritional supplement for long-term treatment of DILI.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- There are some studies on complementary and alternative medicine to help with prevention of drug-induced liver disease with certain medications.
- Alternative medicine such as herbal supplements can have adverse effects on the liver if they have not been well-tested for use in the general population. Table E4 summarizes hepatotoxic herbal remedies, dietary supplements, and weight loss products.

DISPOSITION

- Hy rule, which is known as a combination of high aminotransferases and jaundice, has been associated with mortality rate of 10% to 50% for various drugs.
- The mortality rate in hepatocellular injury depends on the drug involved.

REFERRAL

Referral to a hepatologist may be needed if the patient develops signs of acute liver failure or chronic liver disease.

PEARLS & CONSIDERATIONS

COMMENTS

- Liver injury can occur due to many different drugs. The NIH has a searchable database of drugs that cause drug-induced liver injury.
- Taking a thorough history and ruling out other causes of liver injury is important.
- Withdrawal of the offending agent is the first and best form of management of the patient.
- Liver enzyme tests need to be carefully monitored with DILI.

PREVENTION

Educating patients about potential hepatotoxic medications and possible drug-to-drug interactions can prevent DILI.

Drug-Induced Parenchymal Lung Disease (DILD)

BASIC INFORMATION

DEFINITION

Damage to lung parenchyma caused by toxic effects of drugs. It is a diagnosis of exclusion.

SYNONYMS

Drug-induced interstitial lung disease
Drug-induced lung toxicity
DILD
Interstitial lung disease, drug-induced
Parenchymal lung disease, drug-induced

ICD-10CM CODE
J70.2 Acute drug induced interstitial lung disorders

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Global incidence is not known but likely accounts for 2.5% to 3% of interstitial lung disease (ILD) cases. More than 350 medications are known to cause pulmonary toxicity, including ILD. In the U.S., up to 10% of patients who receive chemotherapeutic agents develop lung toxicity.
PREVALENCE: Not reported
PREDOMINANT AGE AND SEX: Extreme ends of ages are prone to develop severe drug-induced side effects. Some studies have shown severe side effects in individuals >40 yr of age. Gender is not an independent risk factor.
GENETICS: Limited studies have shown that there may be a racial difference in the incidence of DILD.
RISK FACTORS: Age, sex, ethnicity, drug dose, oxygen, drug interaction, radiation, presence of underlying lung disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presentation is similar to other parenchymal lung diseases including shortness of breath, dry cough, fever, general malaise, and fatigue.
- No pathognomonic clinical, laboratory, physical, radiographic, or histologic findings. DILD is considered a diagnosis of exclusion.
- Lung examination findings are nonspecific and include dry crackles, Velcro rales, and inspiratory squeaks. In advanced stages, clubbing can be seen.

ETIOLOGY

- Mechanism varies by offending drug and is not fully understood in some cases. Both direct cytotoxic effects and immune mechanisms of action may be involved independently or in combination. Table E1 summarizes the histiologic pattern of drug-induced lung disease.
- Two possible routes of exposure have been identified: Inhalation vs. vasculature system.
- Initial exposure leading to acute toxicity may progress to chronic inflammation and fibrotic changes, which interfere with gas exchange.
- Amiodarone is a well-known cause of DILD and is usually associated with DILD at higher doses of administration (≥400 mg daily) in 5% to 15% of patients. The mechanism of lung damage is unknown. Chronic interstitial pneumonitis is the most common manifestation of amiodarone pulmonary toxicity, but there are reports of confluent lesions occurring as a result of amiodarone pneumonitis. Many of these lesions are bronchiolitis obliterans. CT scan of the lung (Fig. E1) can further define these lesions.
- Lung toxicity can occur after weeks to months of both low- and high-dose methotrexate administration. Hypersensitivity pneumonitis is its most common manifestation of lung toxicity. The mechanism by which it occurs is unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute respiratory distress syndrome
- Alveolar proteinosis
- Congestive heart failure
- Diffuse lung diseases
- Hypersensitivity pneumonitis
- Lung malignancy
- Pulmonary infections
- Pulmonary vasculitis syndromes
- Radiation pneumonitis
- Respiratory failure secondary to hypoxia
- Occupational lung diseases:
  1. Asbestosis
  2. Berylliosis
  3. Chemical worker's lung
  4. Coal worker's pneumoconiosis
  5. Farmer's lung
  6. Silicosis
  7. Nitrous dioxide toxicity (i.e., silo filler's disease)
  8. Tobacco worker's lung

WORKUP

- DILD is suspected after exclusion of other etiologies in patients with recent exposure to offending drug.
- Tables E2 and E3 list medications associated with pulmonary toxicities.
- Fig. E2 illustrates various radiographic presentations of DILD.

LABORATORY TESTS

- CBC may show increased eosinophils.
- Arterial blood gas (ABG) may show hypoxemia.

IMAGING STUDIES

- Chest x-ray (Fig. E3)
- CT scan (Fig. E4)
- Other studies include pulmonary function tests (PTFs), flexible bronchoscopy with bronchoalveolar lavage (BAL), open lung biopsy

TABLE E1 Histological Pattern of Drug-Induced Lung Disease

Diffuse Alveolar Damage	Diffuse Alveolar Hemorrhage	Interstitial Pneumonia	Organizing Pneumonia	Eosinophilic Pneumonia
Amiodarone	Anticoagulants Amphotericin B	Amiodarone	Amiodarone Bleomycin Cyclophosphamide	Nitrofurantoin Nonsteroidal antiinflammatory drugs Paraaminosalicylic acid Penicillamine Sulfasalazine
Bleomycin	Cyclophosphamide	Carmustine	Gold salts	
Cyclophosphamide Methotrexate	Cytosine arabinoside (ara-c)	Chlorambucil Cyclophosphamide	Penicillamine	
		Methotrexate Nitrofurantoin	Methotrexate	
	Penicillamine		Nitrofurantoin	
Mitomycin Melphalan Gold salts			Sulfasalazine	

From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.

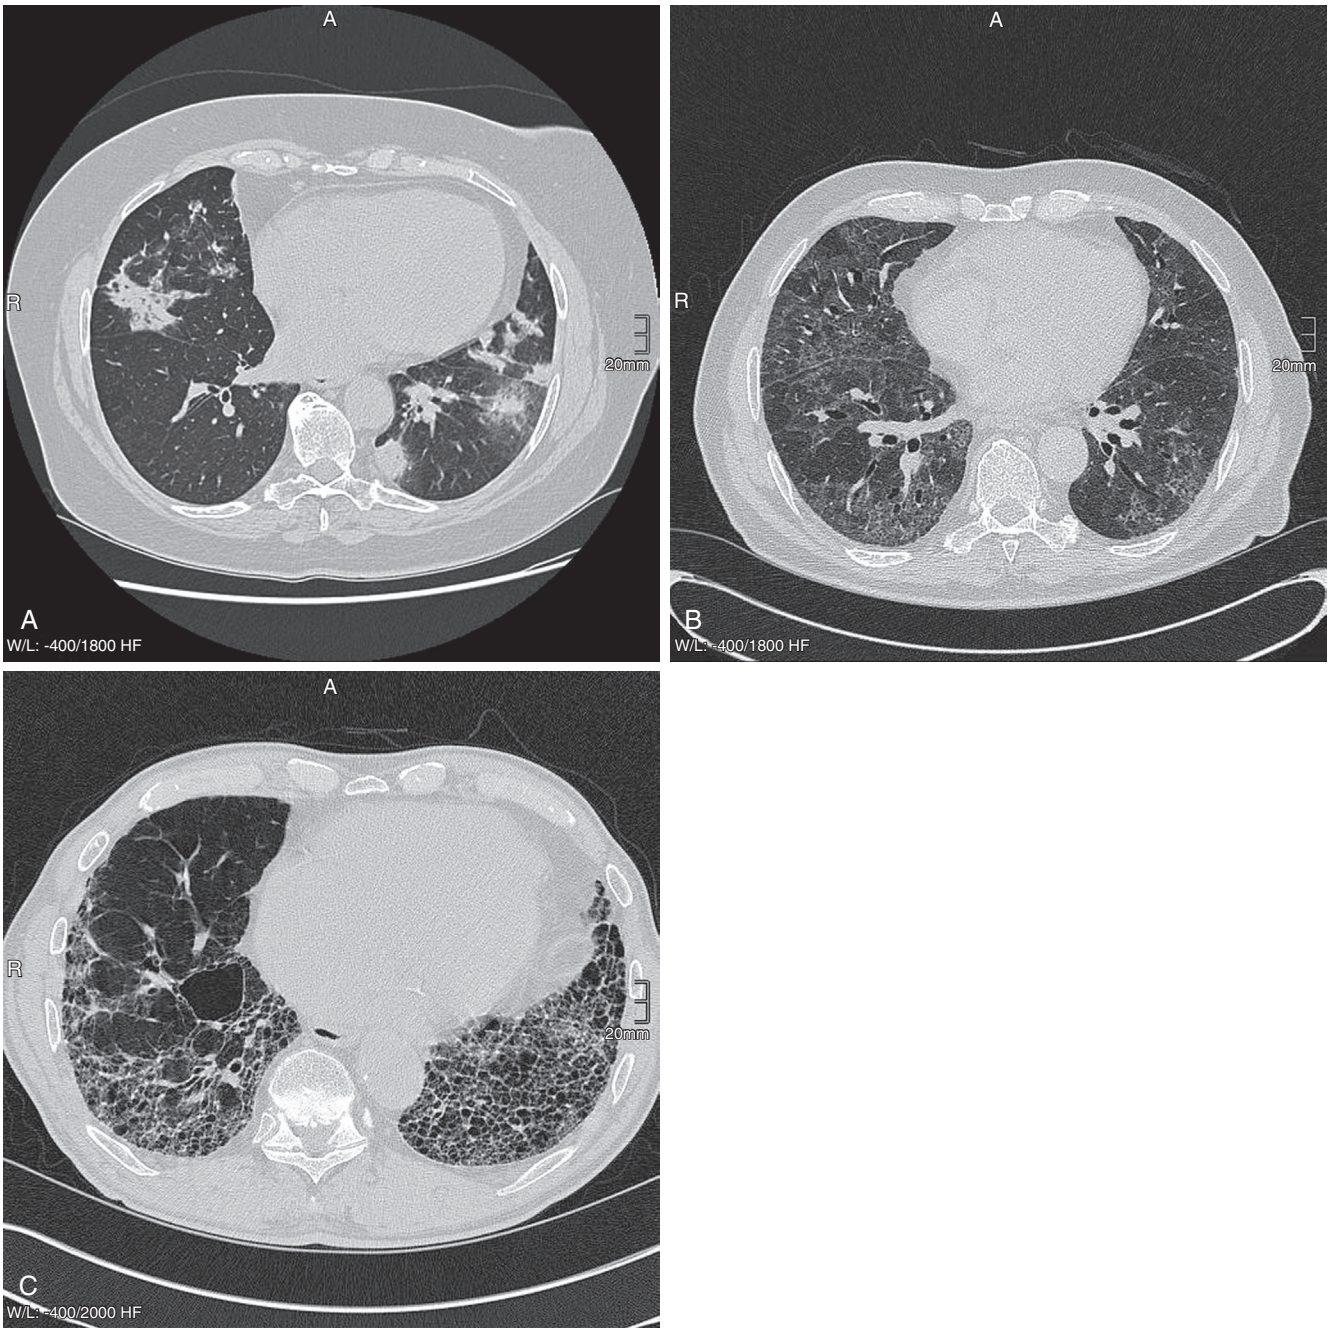

FIG. E1 Radiologic examples of drug-induced parenchymal lung disease (DILD). A, Cryptogenic organizing pneumonia. **B,** Nonspecific interstitial pneumonia. **C,** Usual interstitial pneumonia. (From Schwaiblmair MM et al: Drug induced interstitial lung disease, *Open Respir Med J* 6:63-74, 2012.)

Rx TREATMENT

There is no specific recognized treatment of DILD other than removal of offending agent.

NONPHARMACOLOGIC THERAPY

Removal of offending agent. Supportive measures including smoking cessation, control of underlying lung disease, and prompt treatment of concomitant respiratory infection.

ACUTE GENERAL Rx

Glucocorticoids have been used with rapid improvement in gas exchange and reversal in radiographic abnormalities.

CHRONIC Rx

None

COMPLEMENTARY & ALTERNATIVE MEDICINE

Lung transplantation in cases of severe irreversible fibrosis

DISPOSITION

Most patients can be treated in the community setting. Transfer to a tertiary center is indicated when diagnosis is unclear.

REFERRAL

For workup and diagnosis, early involvement of a pulmonary specialist is advised.

TABLE E2 Drugs Associated with the Development of Interstitial Lung Disease

Antimicrobial Agents
- Aspirin
- Etanercept
- Gold
- Infliximab
- Methotrexate
- Nonsteroidal antiinflammatory drugs
- Penicillamine

Antiinflammatory Agents
- Amphotericin B
- Isoniazid
- Nitrofurantoin
- Sulfasalazine

Biological Agents
- Adalimumab
- Alemtuzumab
- Bevacizumab
- Cetuximab
- Rituximab
- Trastuzumab
- Tumor necrosis factor (TNF)-α blockers

Cardiovascular Agents
- ACE inhibitors
- Amiodarone
- Anticoagulants
- β-Blockers
- Flecainide
- Hydrochlorothiazide
- Procainamide
- Statins
- Tocainide

Chemotherapeutic Agents
- Azathioprine
- BCNU
- Bleomycin
- Bortezomib
- Busulfan
- Carmustine
- Chlorambucil
- Colony-stimulating factors
- Cyclophosphamide
- Cytarabine
- Deferoxamine
- Docetaxel
- Doxorubicin
- Erlotinib
- Etoposide
- Fludarabine
- Flutamide
- Gefitinib
- Gemcitabine
- Hydroxyurea
- Imatinib
- Interferons
- Lomustine
- Melphalan
- Methotrexate
- Methyl-CCNU
- Mitomycin-C
- Nitrosoureas
- Paclitaxel
- Procarbazine
- Thalidomide
- Vinblastine
- Zinostatin

Miscellaneous
- Bromocriptine
- Carbamazepine
- Cabergoline
- Methysergide
- Penicillamine
- Phenytoin
- Sirolimus
- Talc

ACE, Angiotensin-converting enzyme; *BCNU,* bischloroethyl nitrosourea (carmustine); *CCNU,* chloroethyl cyclohexyl nitrosourea (lomustine).
From Schwaiblmair M et al: Drug induced interstitial lung disease, *Open Respir Med J* 6:63-74, 2012.

PEARLS & CONSIDERATIONS

COMMENTS

- DILD can manifest as noncardiogenic pulmonary edema (NCPE)/capillary leak syndrome, hypersensitivity reaction, cryptogenic pulmonary edema, or interstitial pneumonitis. Almost all histopathologic subtypes of ILD may be observed.
- PFT findings are usually consistent with restrictive lung disease, demonstrating reduced total lung capacity (TLC) as well as reduced diffusion capacity of the lung (DLCO).
- BAL findings are nonspecific but may be helpful in the right context. Low CD4+ to CD8+ ratio suggests DILD. Elevated eosinophils (>40%) can be seen in patients with DILD.

PREVENTION

- When prescribing drugs known to cause DILD, close observation is in order.
- Avoidance of unnecessary drug administration.

TABLE E3 Pharmacologic Action of Selected Chemotherapeutic Agents with Associated Pulmonary Toxicities

Antibiotic-Derived Agents
- Bleomycin
- Mitomycin C

Alkylating Agents
- Busulfan
- Cyclophosphamide
- Chlorambucil
- Melphalan

Antimetabolites
- Methotrexate
- 6-Mercaptopurine
- Azathioprine
- Cytosine arabinoside
- Gemcitabine
- Fludarabine

Nitrosoureas
- Bischloroethyl nitrosourea (BCNU)
- Chloroethyl cyclohexyl nitrosourea (CCNU)
- Methyl-CCNU

Podophyllotoxins
- Etoposide
- Paclitaxel
- Docetaxel

Novel Antitumor Agents
- All-*trans* retinoic acid (ATRA)
- Gefitinib
- Imatinib mesylate
- Irinotecan

Immune Modulatory Agents Used in Malignancy
- Interferons
- Interleukin-2
- Tumor necrosis factor α
- Nivolumab
- Pembrolizumab

Other Miscellaneous Chemotherapy Agents
- Procarbazine
- Zinostatin
- Vinblastine

From Mason RJ et al: *Murray & Nadel's textbook of respiratory medicine*, ed 5, Philadelphia, 2010, WB Saunders.

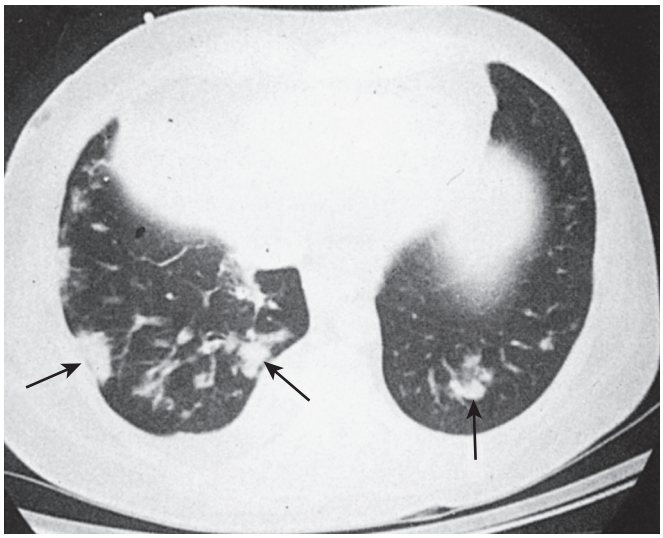

FIG. E2 A computed tomography scan of bleomycin pneumonitis showing a nodular pattern (*arrows*). The histologic features of this form of bleomycin-induced lung injury are typical of bronchiolitis obliterans with organizing pneumonitis. (From Mason RJ et al: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.)

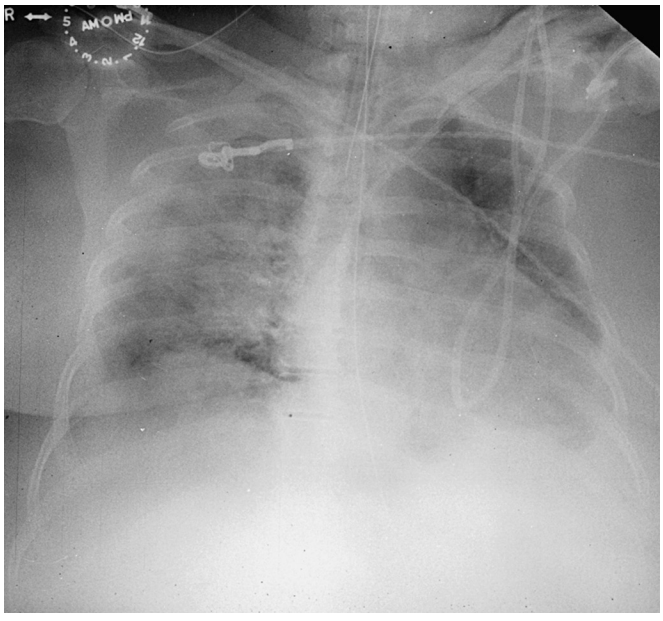

FIG. E3 A chest radiograph of a 44-yr-old woman showing acute noncardiogenic pulmonary edema that resulted from cytosine arabinoside–induced pulmonary disease. Histologic examination typically demonstrates intense intra-alveolar proteinaceous material forming hyaline membranes but little other reaction. (From Mason RJ et al: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.)

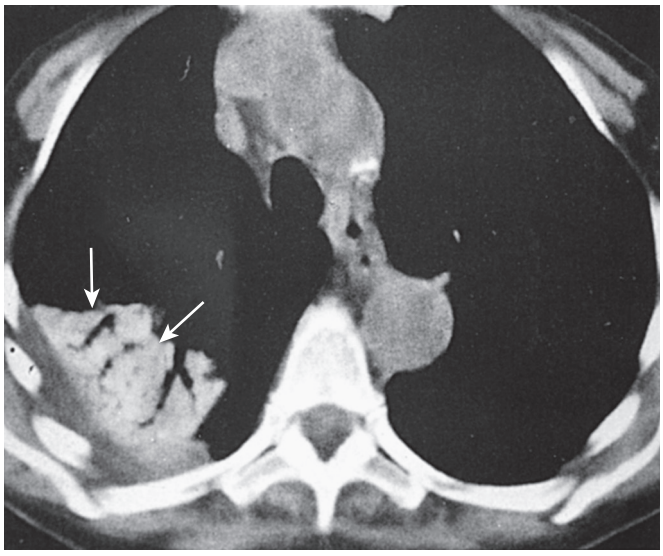

FIG. E4 A chest computed tomography (CT) scan showing confluent pulmonary masses (*arrows*) from amiodarone pneumonitis. Note that the masses are appreciably denser than the surrounding soft tissue in the chest wall in this CT scan obtained without contrast. (From Mason RJ et al: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.)

BASIC INFORMATION

DEFINITION

Drug use disorder is a recurring pattern of harmful use of a substance despite adverse consequences to work, school, relationships, the legal system, or physical health. This may occur concurrently with or independently from *substance dependence,* in which the impairment or distress is more pervasive and often (though not necessarily) includes physical dependence and withdrawal symptoms (Table 1).

SYNONYMS

Substance use disorder
Substance abuse
Addiction

ICD-10CM CODES

F19.129	Other psychoactive substance abuse, unspecified
F10-F19	Defined by specific substance
Z71.51	Drug abuse counseling and surveillance of drug abuser

The new term *substance use disorder* in the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5) combines the categories of substance abuse and substance dependence into a single disorder measured on a continuum from mild to severe.

DSM-5 CODE

Depends on specific drug of abuse

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Alcohol or drug dependence: 5% to 10% of population.

PREVALENCE (IN U.S.): Approximately 15% of patients in primary care practice have an at-risk pattern of drug and/or alcohol use; lifetime prevalence of any alcohol use disorder: 30%; prescription drug misuse is on the rise with 5% past-yr prevalence. Almost 9% of the U.S. population greater than age 12 has used an illicit drug in the past month (2011 National Survey on Drug Use and Health).

PREDOMINANT SEX: Males > females

PREDOMINANT AGE:

- Problematic use of substances may begin in early life (8 to 10 yr).
- Mean age of onset of problem drinking is approximately 25 yr for men and 30 yr for women.

PEAK INCIDENCE: For most substances: Age 15 to 30 yr

DURATION OF CONDITION:

- Men: Average >20 yr of heavy drinking
- Women: Average 15 yr of heavy drinking
- In general, substance use disorders are chronic and relapsing and often progressive

GENETICS: There is evidence of nonspecific genetic factors. Addiction may result in part from underlying, inherited abnormalities in brain structure that impair behavior control and encourage impulsive behavior.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Polysubstance use and comorbidity with psychiatric disorders are common.
- History often reveals recurring behavioral problems, such as relationship, work, or legal problems; violence and traumatic injuries; and anxiety, depression, insomnia, and cognitive and memory dysfunction.
- Repeated requests for early refills of controlled substances and obtaining prescriptions from multiple providers should raise concern for prescription drug use disorder (Table 2).
- Physical findings may include injection marks (Fig. E1), nasal lesions or recurrent epistaxis, poor dentition, scars or bruises from falls or trauma, and poor nutritional status; signs/symptoms of intoxication or withdrawal are highly suggestive of substance use disorder.

ETIOLOGY

Several models of addiction have been proposed:

- Disease model: Addiction is a mental illness, which occurs as a result of the impairment of healthy neurochemical or behavioral processes.
- Genetic model: Genetic predisposition is often a factor in dependency and certain addictive behaviors.
- Social model: Person–environment interactions (i.e., socialization, imitation of observable behavior, and the influence of modeling) shape addictive behavior.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Psychiatric disorders such as depression, mania, psychosis, and anxiety disorders may coexist or occur as a consequence of substance use.
- Rule out seizure disorder and underlying illness.

WORKUP

- A thorough history is crucial for diagnosis.
- The physician's history-taking style and techniques strongly affect patient's willingness to report use and participate in future treatment activities.
- A structured, nonjudgmental approach is generally preferable:
  1. Ask about quantity and frequency of alcohol or drug use. For example, the National Institute on Alcohol Abuse and Alcoholism (NIAAA) declares that *problem drinking* is defined as more than two drinks per day for men and more than one drink per day for women or anyone older than 65 yr.
  2. Use a short screening instrument such as the CAGE questionnaire ("1. Have you ever felt you need to **C**ut down on your alcohol or drug use? 2. Have people **A**nnoyed you by criticizing your alcohol or drug use? 3. Have you ever felt **G**uilty about alcohol or drug use? 4. Have you ever felt you need to drink first thing in the morning [**E**ye opener] to stop shakiness?").
- Problematic behavior during intoxication or withdrawal is diagnostic.

TABLE 1 Key Features of Substance Abuse

1. The substance is often taken in larger amounts over a longer period than intended
2. Unsuccessful efforts to cut down
3. A great deal of time spent obtaining the substance or recovering from its effects
4. Craving
5. Social, occupational, or recreational
6. Recurrent despite hazards
7. Tolerance or withdrawal

Reprinted from Goldman L, Bennett JC (eds): *Cecil textbook of medicine,* ed 22, Philadelphia, 2004, Saunders.

TABLE 2 "Red Flags" for Abuse Behavior and Opioid Addiction

Potential Abuse/Addiction Behaviors*

1. Patient displays an overwhelming focus on opioid issues during clinic visits that occupies a significant proportion of the clinic visit and impedes progress with other pain issues or medical problems.
2. Patient has a pattern of early refills (three or more) or escalating drug use in the absence of acute change or progression of his or her medical condition.
3. Patient generates multiple telephone calls or unscheduled visits to request more opioids, early refills, or problems associated with the opioid prescription that often creates a disturbance of the clinic staff.
4. There is a pattern of prescription problems with reports of medications lost, spilled, or stolen.
5. Patient has supplemental sources of opioids from multiple providers, emergency departments, or illegal sources.

Additional "Red Flag" Abuse Behavior

1. Selling prescribed medications
2. Prescription forgery
3. Stealing another patient's medications
4. Injecting or snorting oral medication
5. Concurrent use of illicit drug(s)
6. Appearing intoxicated or oversedated
7. Insisting on obtaining a specific opioid medication

*Adapted from Chabal criteria for opioid abuse.
From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

- Because self-report of substance use and its consequences can be unreliable, obtaining corroborating information, such as from family members, past detoxifications, or drug rehabilitations, is often helpful.
- Adolescent drug use disorder detection and treatment is extremely challenging. Stages of adolescent substance use are described in Table E3. An assessment for evaluating the seriousness of adolescent drug use disorder is described in Table E4.

LABORATORY TESTS

- Blood alcohol content (BAC) measured on the breath is practical to define intoxication and provides a rough measure of impairment. In general, two standard drinks may cause BAC 0.08% or higher, which is considered legally impaired.
- Obtain toxicology screen in urine or blood samples.
- Biologic markers such as elevated mean corpuscular volume (MCV), γ-glutamyltransferase (GGT), liver function tests (AST and ALT; AST:ALT ratio of 2:1 or greater is suggestive of alcoholic liver disease), and carbohydrate deficient transferrin (CDT) may also be used to diagnose and monitor.

IMAGING STUDIES

Not helpful in routine diagnosis and management of substance abuse, but possibly useful in the management of sequelae of substance abuse (e.g., brain imaging to evaluate the alcohol abuse–associated increased risk of subdural hematomas or increased evidence of cerebral atrophy).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- First assess readiness for change; if precontemplative or contemplative, counsel about risks of use and benefits of abstinence; a motivational interviewing approach has been shown to be effective.
- Nonpharmacologic strategies have the greatest documented efficacy: Advice, feedback, goal setting, problem solving, and additional contacts for further assistance.
- Opiate contracts, prohibiting a patient from getting early refills or obtaining opiates from multiple prescribers, should be considered for all patients with chronic pain receiving opioid painkillers, especially for patients with a history of substance abuse or medication abuse.
- Relapse prevention facilitated by avoidance of trigger stimuli or by uncoupling trigger stimuli from substance ingestion.
- Self-help and 12-step support groups such as Alcoholics Anonymous and Narcotics Anonymous are helpful in achieving and maintaining sobriety.
- Residential or inpatient treatment programs should be a consideration for any individual with continued or escalating use despite outpatient treatment.

ACUTE GENERAL Rx

- Detoxification is an important first step. Seizure risk is greatest within the first 48 hours of alcohol abstinence. Detoxification goals are to facilitate withdrawal and initiate abstinence safely, prevent withdrawal seizures and reduce symptoms, and refer the patient to ongoing treatment.
- Benzodiazepines are effective in acute alcohol withdrawal for the management of symptoms as well as the prevention of seizures. One strategy is to give the patient a loading dose of a long-acting benzodiazepine (e.g., 20 mg of diazepam) and then continue the benzodiazepine as scheduled while tapering down the dose gradually. An example would be chlordiazepoxide 25 to 50 mg every 6 hours on day 1, 25 to 50 mg every 8 hours on day 2, 25 to 50 mg every 12 hours on day 3, and 25 to 50 mg at hour of sleep on day 4 and day 5 and then discontinue. An alternative "symptom-driven" strategy is to follow the patient closely with serial assessments, such as the Clinical Institute Withdrawal Assessment for Alcohol (CIWA) scale, and to dose with 1 to 2 mg of lorazepam as needed to treat specified withdrawal symptoms.
- The prophylactic administration of thiamine and folic acid (first intravenously or intramuscularly followed by supplemental oral doses) in alcohol withdrawal is recommended before starting any carbohydrate-containing fluids or food to prevent Wernicke-Korsakoff syndrome (alcoholic encephalopathy and psychosis). Magnesium appears to be effective in the treatment of alcohol withdrawal–related cardiac arrhythmias, but not other symptoms of alcohol withdrawal.
- Beta-blockers and clonidine generally should be avoided in alcohol withdrawal; they may mask markers of the severity of the withdrawal (blood pressure and pulse rate).
- Unlike withdrawal from alcohol or benzodiazepines, opioid withdrawal is not life threatening.
- Clonidine alleviates the discomfort of opiate withdrawal. Clonidine tablets, 0.1 mg q4-6h as needed, can be used while monitoring patient's blood pressure. Clonidine transdermal patch, 0.1 mg/24 hr, can be used to treat autonomic hyperactivity symptoms; however, it has a very slow onset and may take 2 to 3 days to achieve therapeutic levels. Antidiarrheals, ibuprofen, and dicyclomine can be used as adjuncts to treat opiate withdrawal symptoms.
- Methadone taper is an effective approach for detoxification in opioid dependence.
- Buprenorphine is a partial μ-opioid receptor agonist that may be used for detoxification and maintenance in treatment of opioid dependence (see dosing in next section).

LONG-TERM Rx

- Naltrexone helps reduce craving for alcohol. Naltrexone 50 mg once daily for 12 wk can be a useful adjunct to substance abuse counseling or rehabilitation programs. Randomized treatment studies are equivocal for long-term outcomes. Naltrexone reduces relapse and the intensity or frequency of any drinking that does occur. It can be hepatotoxic and is contraindicated in opiate users. Intramuscular naltrexone (380 mg monthly) may be considered if adherence is an issue.
- Acamprosate also helps reduce craving for alcohol. Acamprosate 666 mg three times daily may be an effective adjunct to counseling. A recent meta-analysis showed overall benefit with increase in the number of abstinent days.
- Disulfiram provokes acetaldehyde accumulation after alcohol ingestion, producing a toxic state manifested by nausea, headache, flushing, and respiratory distress. Studies have shown limited efficacy mostly due to noncompliance.
- Topiramate may be an alternative treatment for alcoholism. In a 12-wk randomized trial topiramate up to 300 mg daily significantly reduced the number of heavy drinking days.
- Methadone maintenance for opiate addiction is effective and involves once-daily dosing of methadone in a controlled setting via methadone clinics.
- Buprenorphine is as effective as low-dose methadone and may be prescribed by physicians who have completed approved training. For induction, initiate 12 to 24 hr after short-acting opioid use and 24 to 48 hr after long-acting opioid use. Use buprenorphine/naloxone (Suboxone) tablets in most patients, since buprenorphine-only tablets have risk of abuse. Maximum first-day dosage is 4 to 8 mg of buprenorphine. Titrate buprenorphine dose up to 12 mg on day 2 for signs of withdrawal. Then adjust dosage in frequent outpatient visits (weekly) to minimum needed for maintenance (up to 32 mg daily).
- Naltrexone (oral or injectable) may also be used for maintenance in opioid dependence treatment, though evidence of effectiveness is limited.
- Always combine pharmacotherapy with counseling. There is good evidence that this combination improves outcome.
- Treatment of comorbid psychiatric disorders improves outcomes.
- Intervention may be used to break through **denial** of a person with a serious addictive disorder to help the person acknowledge that he or she suffers from a disorder and agree to treatment.

STIMULANT ABUSE: COCAINE AND METHAMPHETAMINE

COCAINE: Health effects of cocaine use include:

- Constricted blood vessels
- Dilated pupils
- Nausea
- Raised body temperature and blood pressure
- Fast or irregular heartbeat
- Tremors and muscle twitches
- Restlessness

Long-term effects of cocaine use include vulnerability to HIV and hepatitis C infections; malnourishment because cocaine decreases appetite; and movement disorders, including Parkinson disease, irritability and restlessness from cocaine

binges, and severe paranoia and perceptual changes such as auditory hallucinations. Cocaine abuse can cause cardiomyopathy, myocardial infarction and arrhythmias, and cerebrovascular accidents and lower the threshold for seizures.

During cocaine withdrawal patients can experience:

- Depression
- Agitation
- Intense cravings
- Need for higher doses
- Apathy
- Exhaustion
- Long periods of sleep

Behavioral therapy may be used to treat cocaine addiction. Examples include:

- Cognitive-behavioral therapy (CBT)
- Contingency management or motivational incentives—providing rewards to patients who remain substance free
- Therapeutic communities
- Community-based recovery groups, such as 12-step programs

Most pharmacotherapies have been ineffective for treating cocaine use disorder. Bupropion, psychostimulants, and topiramate may improve abstinence. While no government-approved medicines are currently available to treat cocaine addiction, researchers are testing some treatments that have been used to treat other disorders, including:

- Disulfiram (used to treat alcoholism)
- Modafinil (used to treat *narcolepsy*—a disorder characterized by uncontrollable episodes of deep sleep)
- Lorcaserin (used to treat obesity)
- Buprenorphine (used to treat opioid addiction)

Observational studies suggest that cannabidiol may reduce problems related with crack-cocaine addiction, such as withdrawal symptoms, craving, impulsivity, and paranoia.

METHAMPHETAMINE: Even small amounts of methamphetamine can result in many of the same health effects as those of other stimulants, such as cocaine or amphetamines. These include:

- Increased wakefulness and physical activity
- Decreased appetite
- Faster breathing
- Rapid and/or irregular heartbeat
- Increased blood pressure and body temperature

Injecting methamphetamine increases risk of contracting HIV and hepatitis B and C. Methamphetamine use can also alter judgment and decision making leading to risky behaviors, such as unprotected sex, which also increases risk for infection. Methamphetamine may worsen the progression of HIV/AIDS and its consequences. Long-term methamphetamine use has many other negative consequences, including:

- Extreme weight loss
- Addiction
- Severe dental problems ("meth mouth")
- Intense itching, leading to skin sores from scratching
- Anxiety
- Changes in brain structure and function
- Confusion
- Memory loss
- Sleeping problems
- Violent behavior
- Delusions
- Hallucinations

There are no approved medications for methamphetamine treatment, although medications are used for symptoms such as psychotic symptoms. Behavior therapies such as CBT and contingency management or motivational incentives as noted above for cocaine treatment are also used for methamphetamine treatment.

DISPOSITION

- Substance abuse is a chronic relapsing illness, so relapses are best approached as part of the course of the illness, as opposed to treatment failure.
- The goal of treatment is always abstinence, but success of treatment is measured by return of function, increasing duration between relapses, and prevention of sequelae of use.

REFERRAL

Physicians should refer patients who do not make progress on changing substance use patterns to addiction specialists and/or specialized substance abuse programs. Patients with comorbid psychiatric illness should be referred for mental health care.

PEARLS & CONSIDERATIONS

- The opioid crisis, which has led to an epidemic of overdose deaths in the U.S., was partially fueled by the use of oral narcotics in the treatment of chronic pain and this has prompted a revision of chronic pain management with strict guidelines for the use of opiate medications for this condition.
- Fentanyl involvement in opioid overdose deaths rose from 14.3% in 2010 to 46% in 2016 (National Vital Statistics System data). Fentanyl is now involved in more deaths than prescription opioids (40% in 2016) or heroin (36.6% in 2016). In many deaths, more than one drug is involved, and combining fentanyl with heroin may enhance its lethality.
- Acute withdrawal from alcohol can become life threatening.
- Withdrawal from opioids can resemble a severe case of the flu.
- A brief intervention (providing information and advising the patient to reduce consumption of alcohol) by the primary care doctor has been demonstrated in randomized trials to reduce drinking in at-risk patients.
- Treatment rates for alcohol use disorders remain low despite available effective treatments.

TABLE E3 Stages of Adolescent Substance Abuse

Stage	Description
1	Potential for abuse Decreased impulse control Need for immediate gratification Available drugs, alcohol, inhalants Need for peer acceptance
2	Experimentation: Learning the euphoria Use of inhalants, tobacco, marijuana, and alcohol with friends Few, if any, consequences Use may increase to weekends regularly Little change in behavior
3	Regular use: Seeking the euphoria Use of other drugs, e.g., stimulants, LSD, sedatives Behavioral changes and some consequences Increased frequency of use; use alone Buying or stealing drugs
4	Regular use: Preoccupation with the "high" Daily use of drugs Loss of control Multiple consequences and risk-taking Estrangement from family and "straight" friends
5	Burnout: Use of drugs to feel normal Polysubstance use/cross-addiction Guilt, withdrawal, shame, remorse, depression Physical and mental deterioration Increased risk-taking, self-destructive, suicidal

LSD, Lysergic acid diethylamide.

TABLE E4 Assessing the Seriousness of Adolescent Drug Use Disorder

Variable	0	+1	+2
Age (yr)	>15	<15	
Sex	Male	Female	
Family history of drug use disorder		Yes	
Setting of drug use	In group		Alone
Affect before drug use	Happy	Always poor	Sad
School performance	Good, improving		Recently poor
Use before driving	None		Yes
History of accidents	None		Yes
Time of week	Weekend	Weekdays	
Time of day		After school	Before or during school
Type of drug	Marijuana, beer, wine	Hallucinogens, amphetamines	Whiskey, opiates, cocaine, barbiturates

Total score: 0-3, less worrisome; 3-8, serious; 8-18, very serious.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

BASIC INFORMATION

DEFINITION

Dumping syndrome refers to a constellation of postprandial symptoms resulting from rapid delivery of hypertonic stomach contents into the small bowel that is most often caused by gastric surgery, such as procedures for peptic ulcer disease and gastric bypass.

SYNONYMS

Postgastrectomy syndrome
Rapid gastric emptying
Postprandial hyperinsulinemic hypoglycemia (PHH; late dumping syndrome)
Post-gastric bypass hypoglycemia (PGBH; late dumping syndrome)

ICD-10CM CODE
K91.1 Postgastric surgery syndromes

EPIDEMIOLOGY & DEMOGRAPHICS

Twenty percent to 50% of postgastric surgery patients are estimated to suffer from dumping-related symptoms. Ten percent to 20% with more pronounced symptoms, 1% to 5% with severe symptoms (these data were reported from studies in the 1980s)

- Vagotomy and pyloroplasty (8.5% to 20%)
- Vagotomy and antrectomy (4% to 27%)
- Subtotal gastrectomy (10% to 40%)
- Parietal cell vagotomy (3% to 5%)
- Gastric bypass surgeries (≤50%)
- Males and females are affected equally

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Early dumping syndrome: Symptoms start within 1 hr after eating food:
  1. No symptoms in fasting state
  2. Early satiety, nausea, vomiting, and belching
  3. Epigastric fullness, cramping, and diarrhea
  4. Dizziness, flushing, diaphoresis, and syncope
  5. Palpitations and tachycardia
- Late dumping syndrome: Symptoms occurring 1 to 3 hr after eating:
  1. Dizziness, diaphoresis
  2. Irritability, fatigue
  3. Difficulty in concentration
  4. Tremulousness, anxiety, palpitations
  5. Confusion, seizure, coma

ETIOLOGY

Dumping syndrome occurs almost exclusively in patients who have had gastric surgery. However, nonsurgical etiologies do exist.

- Systemic symptoms in early dumping syndrome are thought to be partially due to hypovolemia caused by rapid shifts of fluid from the intravascular space into the lumen of the bowel as well as increased release of GI hormones that disrupt motility and hemodynamic status.
- Increase in vasoactive substances related to rapid gastric emptying is thought to play a role in dumping syndrome.
- Late dumping symptoms are thought to be due to reactive hypoglycemia and release of counter-regulatory hormones, especially norepinephrine.

DIAGNOSIS

A detailed clinical history and evidence of prior gastric surgery are necessary for the diagnosis.

DIFFERENTIAL DIAGNOSIS

- Gastroparesis
- Pancreatic insufficiency
- Inflammatory bowel disease
- Afferent loop syndromes
- Bile acid reflux after surgery
- Bowel obstruction
- Gastroenteric fistula

WORKUP

Diagnosis is typically made on clinical grounds. In certain clinical settings in which patients exhibit symptoms with no prior history of gastric surgery, oral glucose challenge and imaging studies may be pursued and aid in establishing the diagnosis.

LABORATORY TESTS

Oral glucose challenge test:

- After overnight fasting, oral intake of 50 g of glucose is followed by serial measurements of heart rate, serum glucose, and hydrogen breath test every 15 to 30 min for 3 to 6 hr. A 30-min hematocrit can also be taken.
- An increase in the heart rate >12 beats/min and a rise in hydrogen breath excretion have a sensitivity of 94% and specificity >92%. An increase of >3% in the 30-min hematocrit is also suggestive of a positive test. A nadir blood glucose <3.3 mmol/L (<59 mg/dl) was present in 75% of late dumpers.

IMAGING STUDIES

- Upper GI series properly defines anatomy.
- Scintigraphic imaging documents rapid gastric emptying and may be useful in patients with dumping syndrome and no history of gastric surgery.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Diet modification is first-line treatment in Dumping syndrome:
  1. Divide caloric intake over six small meals.
  2. Limit fluid intake with meals (try to avoid fluids 30 min before meals and following meals).
  3. Decrease carbohydrate intake and avoid simple sugars.
  4. Increase protein and fat intake.
  5. Increase or supplement dietary fibers.
  6. Avoid milk and milk products.
  7. Avoid alcohol.
- Lying down for 30 minutes after a meal to slow gastric emptying and diminish symptoms of hypovolemia may be helpful.

ACUTE GENERAL Rx

- Acarbose 50 mg PO daily can be tried if dietary modification does not help.
- Octreotide 25 to 50 mg SC 30 min before meals is effective in relieving symptoms of dumping syndrome. (In 2009 a small study of 30 patients showed that when given monthly long-acting octreotide, patients reported relief of symptoms and preferred this to subcutaneous octreotide tid.)
- Pectin and guar have been used to increase viscosity of intraluminal contents and relieve symptoms from rapid emptying and absorption.
- Diazoxide 50 mg PO twice daily can be used to inhibit insulin secretion and can be used to treat late dumping hypoglycemia when acarbose/diet modifications are inadequate.

CHRONIC Rx

- Surgery is considered in patients with severe symptoms refractory to the above-mentioned dietary and acute general treatment.
- Surgical procedures include reconstruction of the pylorus, converting Billroth II to a Billroth I anastomosis, Roux-en-Y reconstruction, enteral tube feedings, and reversal of gastric bypass.
- In severe cases, can consider depot long-acting-release octreotide, given as 10 mg intramuscularly every 4 wk for symptom relief.

DISPOSITION

- Dumping syndrome improves with time. Approximately 1% to 2% of patients will continue to have significant symptoms several months after surgery.
- Early dumping syndrome is typically self-limiting and resolves within 7 to 12 wk.
- Dietary modification effectively treats the majority of patients.

REFERRAL

- A GI specialist consult is recommended in patients suspected of having dumping syndrome.
- If medical management is unsuccessful, a general surgical consultation is warranted.

PEARLS & CONSIDERATIONS

COMMENTS

- The majority of patients usually manifest with early dumping symptoms or a combination of early and late symptoms. Few have late dumping symptoms alone.
- Octreotide has an inhibitory effect on the release of insulin and other vasoactive substances released by the gut. It also works by decreasing gastric emptying.
- A notable nonsurgical association with dumping syndrome is diabetes mellitus, and idiopathic cases have been reported.
- Malnutrition is a primary concern for patients with dumping syndrome. Patients may modify their eating habits as a result of dumping syndrome.

BASIC INFORMATION

DEFINITION

Dupuytren contracture is a disease of the palmar fascia characterized by nodular fibroblastic proliferation that progresses into bands of fibrous tissues. These bands eventually result in contractures of the palmar fascia. As the fibrous bands thicken, they also shorten, leading to permanent flexion deformities of the finger joints. The ring finger tends to be the most commonly affected digit. Dupuytren diathesis is a more aggressive presentation of the disease.

SYNONYMS

Palmar fibroma
Palmar fibromatosis

ICD-10CM CODE

M72.0 Palmar fascial fibromatosis [Dupuytren]

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Varies by ethnicity but estimated at 3 per 10,000 men in the U.S.

PREVALENCE: Varies depending on ethnicity and age. In the U.S., the overall prevalence is estimated to be about 7% but can be as high as 30% in males over age 65.

PREVALENT SEX: Male:female ratio of 5.9:1. Approaches a 1:1 ratio after age 80

PREVALENT AGE: Increases significantly after age 40

GENETICS: No specific gene has been identified that is responsible for Dupuytren contracture, although abnormalities in the Wnt signaling pathway have been implicated. However, many studies have shown inheritance to be polygenetic with variable penetrance.

RISK FACTORS: Age older than 40 yr, male sex, northern European descent, positive family history, diabetes mellitus, alcoholism, smoking, HIV infection, hyperlipidemia, and exposure to vibration

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Usually asymptomatic, but the flexed fingers can interfere with use of the affected hand (Fig. E1).
- Isolated, painless palmar nodules that eventually harden and progress into a cord that extends into the finger. As the cord enlarges, it also contracts, creating the flexion deformity usually seen at the metacarpophalangeal (MCP) or proximal interphalangeal (PIP) joints.
- Skin pitting.
- Process usually begins on the ulnar side of the hand, often starting at the ring finger, but other fingers can also become involved over time.
- Tabletop test of Hueston: Place hand and fingers prone on a table. Test is positive if hand will not go flat (Fig. E2). Surgery is generally not indicated if test is negative.
- A staging classification for Dupuytren contracture is described in Table E1.

ETIOLOGY

The cause of Dupuytren contracture is unknown; however, there seems to be some genetic predisposition to this disorder. There is evidence that a T-cell–mediated autoimmune response may cause proliferation of myofibroblasts, the cells typically implicated in development of the nodules. Male sex, environmental exposures (e.g., smoking, vibrational devices), and certain diseases (e.g., HIV, DM) also seem to play a role in acquiring this disorder.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Trigger finger
- Soft tissue tumor
- Camptodactyly
- Volkmann contracture
- Traumatic scars
- Tendon cyst
- Fracture malunion

IMAGING STUDIES

Imaging studies are not necessary to establish the diagnosis of Dupuytren contracture. Plain film radiographs and advanced imaging (CT scan or MRI) may be helpful if considering other differential diagnoses.

TREATMENT

- Mild disease: Avoidance of repetitive hand trauma; measures include the use of padded gloves and the use of pipe insulation or cushion tape to build up handles. Physical therapy and stretching exercises can be tried; however, strong evidence does not exist to support routine use.

FIG. E1 Dupuytren contracture. A flexion deformity of the finger is present, with nodular thickening of the fascia to the ring finger.

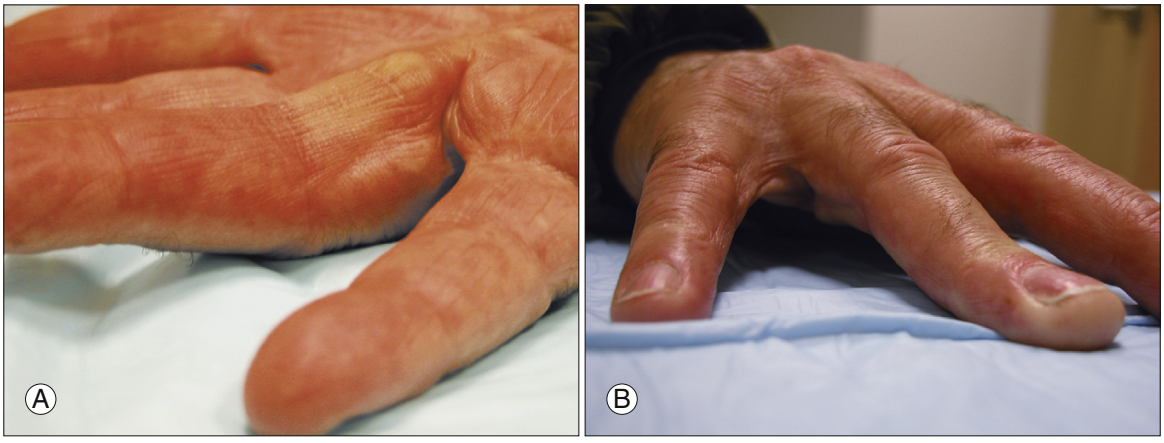

FIG. E2 Dupuytren contracture of the ring finger. A, Pitting of the skin and a longitudinal cord causing flexion of the metacarpophalangeal (MCP) joint can be seen. **B,** A contracture and flexion deformity at the MCP joint keep this patient from flattening his hand against a flat surface. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

TABLE E1 Staging Classification for Dupuytren Contracture

Stage	Description	Management
1	Early palmar disease with no contracture	Leave alone
2	One finger involved, with only metacarpophalangeal joint contracture	Surgery
3	One finger—metacarpophalangeal joint 1 proximal interphalangeal joint	Surgery difficult
4	More than one finger involved	Surgery prolonged and only partly successful
5	Finger-in-palm deformity	Consider amputation

From Parvizi J: *High-yield orthopedics,* Philadelphia, 2010, Saunders.

- Moderate disease: Intralesional corticosteroid injection can be effective in softening and flattening nodules without significant joint contracture, especially if there is tenderness associated with a palmar nodule. Percutaneous needle aponeurotomy has also shown good results, especially if the majority of the contracture is at the MCP joint rather than at the PIP joint. However, more than 85% of contractures recur after undergoing needle aponeurotomy. Enzymatic fasciotomy by *Clostridium histolyticum* collagenase injection for early and less severe cases (less than 50 degrees contracture) has shown good efficacy. Collagenase *C. histolyticum* (Xiaflex) is the first FDA-approved, nonsurgical treatment option for adult Dupuytren contracture patients with a palpable cord and has been shown to reduce the nodule size and hardness. A prospective study with collagenase injections performed in Sweden showed maintained clinical improvement in 72% of patients at 2 yr, including complete contracture correction of MCP joints in more than 80% of patients but less than 50% of PIP contractures. This overall clinical improvement was maintained in about 64% of patients at the 3-yr time point. Collagenase injections continue to be an excellent, safe option for patients with moderate disease.
- Severe disease: Surgery is usually performed when the metacarpophalangeal joint contracture exceeds 30 degrees, the proximal interphalangeal joint exceeds 20 degrees of contracture, or the tabletop test of Hueston is positive. Another indication for surgery is neurovascular damage of the finger.
- Complications: Flexor tendon rupture is a rare but serious complication, which can result from collagenase injection. Surgery that involves excision of the pathologic cords and nodules may directly injure or cause stretch neuropraxia to the neurovascular bundle.

REFERRAL

Evaluation by a hand surgeon is warranted if joint contracture begins to develop or for excision of a nodule that is painful (at any stage).

PEARLS & CONSIDERATIONS

COMMENTS

- Approximately 5% of patients develop a similar condition elsewhere, such as Peyronie disease or Ledderhose disease (involvement of the plantar fascia).
- Tender knuckle pads *(Garrod knuckle pad)* over the dorsal aspect of the PIP joints may also be present.
- Individuals with these additional findings are considered to have Dupuytren diathesis, and their disease is generally more severe and recurrent.

BASIC INFORMATION

DEFINITION

Dysmenorrhea is painful menstrual cramps of uterine origin. Prevalence is estimated to vary between 45% and 95%. Dysmenorrhea is the most common gynecologic condition in women, regardless of age and nationality.

Types of Dysmenorrhea:

- Primary dysmenorrhea is menstrual pain without organic disease.
- Secondary dysmenorrhea is menstrual pain associated with an identifiable disease.

SYNONYMS

Menstrual cramps
Painful periods

ICD-10CM CODES

N94.3 Primary dysmenorrhea
N94.5 Secondary dysmenorrhea
N94.6 Dysmenorrhea, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Approximately 50% of menstruating women are affected by dysmenorrhea, with approximately 10% of them having severe dysmenorrhea with incapacitation for 1 to 3 days/mo.
- Dysmenorrhea is most common in the age group from 20 to 24 yr.
- Primary dysmenorrhea may appear 6 to 12 mo after ovulatory menstrual cycles begin.
- Secondary dysmenorrhea may occur at any time after menarche, but it may arise in a woman's 30s to 40s due to a causative underlying condition. The woman may also complain of dyspareunia, menorrhagia, intermenstrual bleeding, or postcoital bleeding.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Sharp, crampy, midline, lower abdominal pain without a lower quadrant or adnexal component but possible radiation to the lower back and upper thighs
- Unremarkable pelvic examination in nonmenstruating patient
- Accompanying symptoms: Nausea, vomiting, headaches, anxiety, fatigue, diarrhea, fainting, and abdominal bloating
- Cramps usually lasting <24 hr and seldom lasting >2 to 3 days
- Secondary dysmenorrhea: Dyspareunia is a common complaint, and bimanual pelvic-abdominal examination may demonstrate uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, a pelvic mass, or an enlarged, irregular uterus

ETIOLOGY

Prostaglandin $F_2\alpha$ is the agent responsible for dysmenorrhea. It stimulates uterine contractions and cervical stenosis (narrowing) and increases vasopressin release. Behavior and psychological factors have also been implicated in the etiology of primary dysmenorrhea. Primary dysmenorrhea only occurs in ovulatory cycles. Secondary dysmenorrhea is usually caused by endometriosis, adenomyosis, leiomyomas, and, less commonly, intrauterine device (IUD) use, or congenital or acquired outflow tract obstruction, including cervical stenosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS: SECONDARY DYSMENORRHEA

- Adenomyosis
- Adhesions
- Cervical structures or stenosis
- Congenital malformation of Müllerian system
- Ectopic pregnancy
- Endometriosis
- Imperforate hymen
- IUD use
- Leiomyomas
- Ovarian cysts
- Pelvic congestion syndrome
- Pelvic inflammatory disease
- Polyps
- Transverse vaginal septum
- Table 1 summarizes the differential diagnosis of dysmenorrhea in adolescents

WORKUP AND EVALUATION

- Primary dysmenorrhea: Characteristic history, physical examination and ultrasound normal with the absence of an identifiable cause of pelvic pain
- Secondary dysmenorrhea: Physical examination and ultrasound may reveal vaginal/uterine abnormalities, fibroids, adenomyosis, polyps, endometriomas

LABORATORY TESTS

- No specific tests diagnostic for dysmenorrhea
- Elevated white blood cell count in the presence of infection
- Human chorionic gonadotropin to rule out ectopic pregnancy

IMAGING STUDIES

- Ultrasound scan of the pelvis to evaluate the presence of leiomyomas, adenomyosis, ovarian cysts
- Saline ultrasonography to assess the uterine cavity to rule out endometrial polyps or submucosal or intraluminal leiomyomas

TREATMENT

NONPHARMACOLOGIC THERAPY

- Applying heat to the lower abdomen with hot compresses, heating pads, or hot water bottles seems to offer some relief.
- Offer reassurance that this is a treatable condition.

ACUTE GENERAL Rx

- Treatment of dysmenorrhea is summarized in Table 2

TABLE 1 Differential Diagnosis of Dysmenorrhea in Adolescents

	PRESENTATION	DIAGNOSIS
Primary	Crampy pelvic pain may be accompanied by aching/heaviness in lower back and upper thighs, nausea, emesis, diarrhea, headache, mastalgia, fatigue, and dizziness; symptoms begin at or shortly before onset of menstrual flow and last 1-3 days.	Normal physical exam; internal exam only for sexually active adolescents. Ultrasound can be reserved for those patients with atypical presentations (e.g., onset at menarche) or those whose pain does not respond to NSAIDs and hormonal therapy.
Endometriosis and adenomyosis*	**Increasingly severe dysmenorrhea despite adequate therapy;** pain exacerbated during menses can occur acyclically as well.	Increased risk in patients with obstructive anomalies and possibly bleeding disorders; however, most teenagers with endometriosis have normal anatomy and bleeding indices; diagnosis is made visually during surgery. *Found in up to 69% of adolescents who underwent laparoscopy for persistent pelvic pain.*
Müllerian anomalies with partial outflow obstruction	**Pain begins at or shortly after menarche** and occurs with bleeding; presence of **known renal tract anomaly** (often coexists with Müllerian anomaly).	Pelvic ultrasound will demonstrate uterine anomalies (e.g., rudimentary uterine horn); MRI may be required to identify some lesions (e.g., obstructed hemivagina). *Found in 8% of adolescents who underwent laparoscopy for persistent pelvic pain.*
Pelvic inflammatory disease	Abrupt onset of dysmenorrhea more severe than baseline in a sexually active adolescent; presentation can range from mild discomfort to acute abdomen.	Clinical diagnosis made by findings of uterine or adnexal tenderness on bimanual pelvic examination; supporting features include dysuria, dyspareunia, **vaginal discharge,** fever, and increased white blood cell count.
Pregnancy complication	Coincident pain and bleeding may be misdiagnosed as dysmenorrhea.	Urine test positive for human chorionic gonadotropin.

Bold entries indicate "red flags" for diagnosis.
*Adenomyosis is the presence of endometrial tissue within the uterine myometrium.
From Kliegman, RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

TABLE 2 Treatment for Dysmenorrhea

	MEDICATION	REGIMEN	COMMENTS
NSAIDs for up to 5 days	Ibuprofen, 200 mg	2 tablets PO q 4-6 hr	Over-the-counter
	Naproxen sodium, 275 mg	550 mg loading dose, then 275 mg PO q 6 hr	Patients may prefer the equivalent 550 mg PO q 12 hr dosing regimen
	Celecoxib (cyclooxygenase [COX]-2 inhibitor)*	400 mg, then 200 mg PO q 12 hr prn pain	Can be used for patients with von Willebrand disease
Hormonal contraception	Combined oral contraceptive pills or vaginal ring	Continuous hormone regimens (vs standard 21 hormone days followed by 7 placebo days) may offer better relief but may increase the risk of unexpected intermenstrual bleeding	The data favoring rings and pills over the combined hormone patch for this indication are sparse; treatment can be based on patient preference.
	Progestin-only methods	DMPA 150 mg IM or 104 mg SC q 3 mo; levonorgestrel intrauterine device for up to 5 yr; etonogestrel implant for up to 3 yr	DMPA has potential side effects of weight gain and interference with expected bone density increase during adolescence, as well as a higher discontinuation rate than LARC methods.
Gonadotropin-releasing hormone agonist	Depot leuprolide	11.25 mg IM q 3 mo	Consider for patients with presumed endometriosis not responsive to hormonal methods; add-back hormones are recommended to prevent bone loss.

*This medication may cause serious cardiovascular and gastrointestinal events. Use with caution in patients with impaired renal or liver function, heart failure, or a history of GI bleeding or ulcer. Full prescribing information can be found at: www.accessdata.fda.gov/drugsatfda_docs/label/2011/020998s033,021156s003lbl.pdf.

DMPA, Depot medroxyprogesterone acetate; *IM,* intramuscular; *LARC*, long-acting reversible contraceptive; *NSAIDs*, nonsteroidal antiinflammatory drugs; *PO,* by mouth; *SC,* subcutaneous.

From Kliegman, RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

- Nonsteroidal antiinflammatory drugs such as ibuprofen 400 to 600 mg q4 to 6h or naproxen sodium 500 mg q12h
- Oral contraceptives cyclically or continuously (taking only active pills), primarily in women with primary dysmenorrhea
- The levonorgestrel-containing IUD is increasingly being used to ameliorate symptoms of dysmenorrhea. Pain improvement has been shown in many cases to be even better than oral contraceptive pills
- Magnesium supplements (research ongoing)
- Thiamine supplements (research ongoing)
- Fish oil supplements (research ongoing)
- Secondary dysmenorrhea: Treatment directed to the specific underlying condition

CHRONIC Rx

Acupuncture and transcutaneous electrical nerve stimulation may be tried. However, there is not enough evidence to support the use of yoga, acupuncture, or massage. In cases in which medical therapy has not worked, laparoscopy or other surgical treatments should be considered depending on the secondary cause of the dysmenorrhea. A directed physical examination looking for gynecologic masses or nodularity should be performed. Nontraditional approaches such as acupuncture have been tried with relief in some patients. The levonorgestrel IUD has been shown to effectively reduce pain in women with primary dysmenorrhea.

DISPOSITION

The majority of patients are satisfactorily treated with good outcomes. Possible chronic complications with primary dysmenorrhea that has not been adequately treated can lead to anxiety and depression. With certain causes of secondary dysmenorrhea, infertility can become a problem.

REFERRAL

If a secondary cause of dysmenorrhea is revealed, refer to the appropriate specialist for further medical or surgical treatment (e.g., gynecologist, urogynecologist, reproductive endocrinologist, pain management center).

Premenstrual Dysphoric Disorder (Related Key Topic)
Premenstrual Syndrome (Related Key Topic)

AUTHOR: **Barbara McGuirk, MD**

BASIC INFORMATION

DEFINITION

Persistent and/or recurrent pain associated with sexual activity that causes marked distress or interpersonal conflict.

SYNONYM

Painful intercourse

ICD-10CM CODES

N94.1 Dyspareunia
F52.6 Dyspareunia not due to a substance or known physiological condition

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (IN U.S.): Affects 10% to 20% of women
PREDOMINANT SEX: Female
AT-RISK POPULATION: No consistent findings regarding:

- Age
- Parity
- Educational status
- Race
- Income
- Marital status
- However, postmenopausal status is significant: More than 50% of postmenopausal women note that sex can be painful

RISK FACTORS: Dyspareunia can lower:

- Frequency of intercourse
- Levels of desire and arousal
- Orgasmic response
- Physical and emotional satisfaction
- General happiness
- Relationship quality

HISTORICAL FACTORS—ASSESSMENT:

- Pain parameters:
  1. Character (dryness, tightness, pain, burning, soreness)
  2. Location (introital, middle, deep vaginal canal)
  3. Onset
  4. Duration
  5. Timing (e.g., during sex or anticipation before sex)
  6. Chronicity (worsening over the yr)
  7. Cyclicity (related to menstrual cycle, other recurrent life events)
  8. Recurrence (one particular partner, positional, more/less frequent)
- Gynecologic history
  1. History of sexually transmitted disease
  2. History of herpes simplex virus (HSV) or human papillomavirus (HPV)
  3. Other sexual dysfunctions
  4. Prior abdominal or gynecologic surgery
  5. Prior pelvic or abdominal radiation
  6. History of endometriosis, adenomyosis, leiomyomata, pelvic mass/ovarian cyst
  7. History of genital or uterine prolapse
  8. History of gynecologic infection
  9. History of pelvic pain
  10. History of menopausal symptoms/genitourinary syndrome of menopause—most common cause of dyspareunia in women over 50 yr old
  11. Diminished lubrication
  12. Sexual misinformation
  13. History of abuse, trauma
  14. Primary vs. secondary dyspareunia (Secondary dyspareunia—prior history of pain-free coitus)
- Obstetric history:
  1. Lacerations
  2. Episiotomy
  3. Operative vaginal birth
  4. Prolonged labor
  5. Difficult vaginal birth
- General medical causes:
  1. History of chronic diseases
  2. Gastrointestinal or genitourinary symptoms
  3. Medications
  4. History of psychological disorders
  5. History of dermatologic condition
  6. Religious beliefs
  7. Generalized anxiety
  8. Stress
  9. Relationship issues

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Visual inspection of lower genital tract:
  1. Discoloration—consider hypopigmented lichen sclerosis
  2. Ulcerations
  3. Discharge
  4. Prolapse
  5. Dysplastic changes
  6. Infestations
  7. Dry/pale/thin vaginal walls
- Physical examination:
  1. Sensitivity to light touch—single or multiple points
  2. Tenderness to palpation—single or multiple points
  3. Genital prolapse:
     a. Uterus
     b. Bladder
     c. Cervix
     d. Vagina
     e. Adnexa
     f. Rectum
     g. Bowel
  4. Longitudinal or transverse vaginal septum
  5. Levator muscle tone
  6. Evidence of previous surgery
  7. Vaginal length, depth, caliber constrictions: Assess for shortened, narrowed and/or absent vagina
  8. Less rugated, friable vaginal walls
  9. Vaginismus—vaginal muscle tightening

ETIOLOGY

- Pathology or alteration of genital-associated tissue
- Psychosocial factors
- Marital or relationship discord
- History of sexual or generalized physical/emotional abuse
- Menopause/aging
- Medication side effect
- Infection

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital deformities (septa/agenesis)
- Imperforate hymen
- Menopausal changes
- Atrophic/aging tissue
- Impaired lubrication
- Aromatase inhibitor usage/low estrogen levels
- Psychogenic
- Vaginismus
- Inadequate foreplay
- Virginity/hymenal factors
- Endometriosis/adenomyosis
- Levator ani myalgia
- Chronic pelvic pain
- Previous surgery (anterior/posterior colporrhaphy, perineorrhaphy, pelvic floor reconstruction, hysterectomy, episiotomy repair, labiaplasty, vaginoplasty):
  1. Alteration in vaginal length, depth, caliber, architecture, shape, elasticity
  2. Adhesions
- Infectious:
  1. HPV
  2. HSV
  3. Candidiasis
  4. *Tinea cruris*
  5. Acute or chronic salpingitis or endometritis
  6. Sexually transmitted infections
- Pelvic carcinoma
- Previous radiation
- Adnexal attachment or tubal prolapse
- Pelvic tumor/leiomyoma/ovarian cyst or torsion
- Uterine prolapse, malposition, enlargement, or retroversion
- Genital prolapse
- Cystourethrocele, rectocele, enterocele
- Urethral or bladder pathology (e.g., interstitial cystitis)
- Pelvic congestion (controversial)
- Vulvar vestibulitis
- Postcoital cystitis
- Broad ligament pathology
- Neuroma at the site of previous episiotomy
- Previous sexual/physical/emotional abuse
- Marital/relationship discord
- Vulvodynia
- Lichen sclerosus
- Contact or allergic dermatitis
- Vitamin A, B, or C deficiency
- Equestrian dyspareunia
- Pudendal neuralgia
- Myofascial pain syndrome
- Rectal/colon pathology
- Structural abnormalities or alterations:
  1. Muscle
  2. Bone
  3. Ligament
  4. Nerve
  5. Adjacent tissues/structures

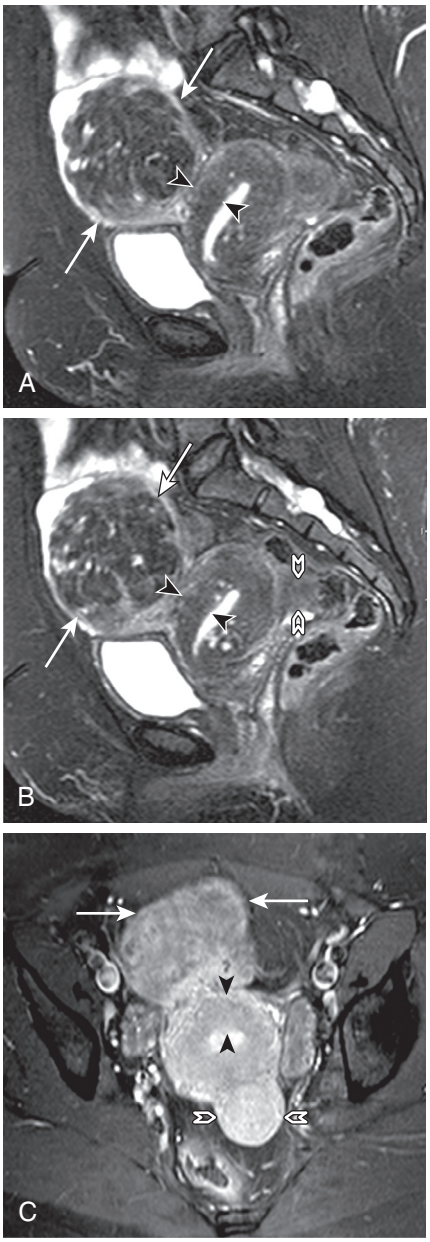

FIG. E1 Adenomyosis and leiomyomata in a 41-yr-old woman with pelvic pain, irregular menses, menorrhagia, and dyspareunia. A and **B,** Sagittal T2-weighted fat-suppressed images show a large anterior subserosal fibroid with mixed but predominantly low signal *(arrows)* and a smaller posterior subserosal fibroid with low to intermediate signal *(chevrons).* There is also widening of the junctional zone *(black arrowheads)* with areas of increased T2 signal, indicative of adenomyosis. **C,** Axial three-dimensional gradient echo postcontrast image with fat suppression shows enhancement of the leiomyomata *(white arrowheads* and *chevrons)* and the thickened junctional zone *(black arrowheads).* (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, Saunders.)

WORKUP

- History and physical examination are key and most likely all that is needed
- If needed (unlikely, however):
  1. Colposcopy
  2. Cystoscopy
  3. Ultrasonography
  4. MRI
  5. Consider laparoscopy for unexplained deep dyspareunia

LABORATORY TESTS

- Wet mount:
  1. Trichomoniasis
  2. Candidiasis
  3. Bacterial vaginosis
- Cultures:
  1. Cervical
     a. Gonorrhea
     b. *Chlamydia*
  2. Vaginal
  3. Lesions
  4. Urine
- Vulva, vaginal, or cervical biopsy
- Pap smear
- HSV antibodies
- Gonadotropin levels

IMAGING STUDIES

Pelvic or abdominal ultrasonography. Transvaginal ultrasonography provides for greater resolution of the uterus and adnexa (tubes/ovaries) due to proximity to pelvic organs. Consider an MRI when the diagnosis is unclear with other diagnostic modalities (Fig. E1).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Patient education
- Discontinue exacerbating activity, irritants, medications
- Lubrication with coitus
- Coital position changes
- Avoid deep thrusting
- Warm or cool soaks
- Reassurance to patient of nonmalignant/other worrisome conditions
- Emphasize that this is a normal aging and postmenopausal finding
- Psychosocial interventions:
  1. Systemic desensitization techniques
  2. Behavior modification
  3. General counseling
  4. Marital/relationship counseling
- Vaginal dilators
- Vaginal muscle exercises and relaxation techniques
- Excision of pathologic tissue
- Surgical correction of altered, reduced, or deformed tissues

ACUTE GENERAL Rx

- Topical lidocaine, nonhormonal moisturizers and lubricants
- Corticosteroids—e.g., for lichen sclerosus
- Antiinfective agents if vaginitis/cervicitis/adnexal abscess is found
- Trigger point injections
- Massage or physical therapy
- Acupuncture
- Transcutaneous electrical nerve stimulation
- Stress reduction techniques
- Safe sexual practices
- Menopausal hormone (estrogen) therapy: To address vulvovaginal atrophy (VVA)/genitourinary syndrome of menopause (GSM)
  1. Local/intravaginal (pill/ring/cream/gel)
  2. Systemic (pill/patch/gel/spray/cream/injection)
- Ospemifene (Osphena), an oral estrogen agonist/antagonist for treatment of moderate to severe dyspareunia in postmenopausal women with suspected vaginal atrophy. Dosage is a 60 mg tablet daily
- Prasterone (Intrarosa), which does not contain estrogen but converts the precursor, DHEA, intravaginally to estrogen and androgen, is used for the treatment of moderate to severe dyspareunia in postmenopausal women with suspected vaginal, vulvar, introital, and/or urogenital atrophy. Dosage is a daily intravaginal pellet insertion
- Imvexxy (Estradiol) is a bio-identical estradiol vaginal insert used to treat moderate to severe dyspareunia in postmenopausal women. The dosage is a daily placement of the vaginal insert for the first two wk, followed by twice weekly application
- Antiviral agents
- Intralesional interferon
- Mild analgesics
- Antidepressants

CHRONIC Rx

All the previous plus:

- Set supportive visits as needed
- Oral contraceptives
- Regular sexual activity
- Balanced diet
- Vitamin supplementation
- Proper hygiene

DISPOSITION

Most patients will have a reduction and/or resolution of their symptoms by using the appropriate therapeutic approaches.

REFERRAL

As with other pain conditions, a multidisciplinary approach using the expertise of psychologists, dermatologists, gynecologic surgeons, infectious disease specialists, urologists, and others may be helpful.

! PEARLS & CONSIDERATIONS

- Dyspareunia is a symptom complex resulting from a multitude of etiologies, some of which act simultaneously.
- Uncovering the etiology of dyspareunia is predominantly based on a comprehensive history and physical examination.
- Ask about dyspareunia as part of your routine patient assessment. Don't wait for the patient to initiate the conversation.
- Sorting the differential diagnosis into superficial, intermediate, and deep dyspareunia categories is immensely helpful.

- As with the physical evaluation of any painful condition, attempt—by precise touching (moistened cotton swab), palpation, or applied pressure—to reproduce the patient's chief complaint.
- Performing a one-finger pelvic examination without concurrent abdominal palpation allows a more precise assessment as to the source of genital pain.
- Individualize therapy.
- Initiate and maintain an honest dialogue and compassionate demeanor with the patient and her partner.
- Be open minded, approachable, nonjudgmental, and diligent in your search for a solution to help these often silently suffering patients.

Dyspepsia, Nonulcerative

BASIC INFORMATION

DEFINITION

Dyspepsia is a constellation of symptoms referable to the gastroduodenal region of the upper GI tract. *Nonulcerative dyspepsia* is a term used to describe signs and symptoms of persistent or recurrent dyspepsia that have no identifiable organic cause.

SYNONYMS

Nonulcer dyspepsia
Functional dyspepsia
Idiopathic dyspepsia

ICD-10CM CODE
K30 Functional dyspepsia

EPIDEMIOLOGY & DEMOGRAPHICS

Up to 25% of the general population will experience dyspepsia each yr. Of these, 75% will have no evident causative agent.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Typical clinical presentation is dyspepsia without findings on physical examination to explain the symptoms.

ETIOLOGY

The etiology and pathophysiology are still unclear. Box 1 summarizes causes of dyspepsia. Research is focused on abnormalities of gastric motor function and visceral hypersensitivity, as well as:

- *Helicobacter pylori* infection
- Psychosocial factors—associated with anxiety and depression

RISK FACTORS

Risk factors include the following:

- Genetic predisposition: Homozygous *GNB3* gene
- Dietary habits such as caffeine, alcohol, or smoking
- Medications such as NSAIDs, calcium channel blockers, methylxanthines, alendronate, orlistat, acarbose, and potassium supplements
- Psychological disorders such as anxiety, depression, somatization, or personal history of childhood sexual or physical abuse

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Nonulcerative dyspepsia is diagnosed when all other organic causes have been excluded, including:

- Peptic ulcer disease (PUD)
- Gastroesophageal reflux
- Gastric/esophageal/other abdominal cancers
- Biliary tract disease
- Gastroparesis, including diabetic gastroparesis
- Pancreatitis
- Medications (i.e., NSAIDs, erythromycin)
- Metabolic disturbances (i.e., hypercalcemia, heavy metals, or hyperkalemia)
- Ischemic bowel disease
- Systemic disorders (i.e., eosinophilic gastritis, Crohn disease, sarcoidosis, celiac disease, thyroid disorders)

DIAGNOSIS

The Rome IV criteria lists the following factors, which must be present at least 3 mo and first noticed within 6 mo of diagnosis:

- At least one of the following:
  1. Postprandial fullness, *or*
  2. Early satiety, *or*
  3. Epigastric pain, *or*
  4. Epigastric burning
  5. *And* no evidence of structural disease likely to explain the symptoms

WORKUP

The American Gastroenterological Association, as well as the Maastricht III and the IV European consensus, suggest the following:

- The pattern of symptoms overlaps considerably for all types of dyspepsia; therefore, the history and physical should focus on finding specific symptoms that help exclude other causes of dyspepsia.
- Endoscopy should be performed only in patients >55 yr old and in younger patients with alarming symptoms (e.g., weight loss, progressive dysphagia, recurrent vomiting, evidence of gastrointestinal bleeding, or family history of cancer) presenting with new-onset dyspepsia. Findings consistent with diagnosis of nonulcerative dyspepsia are not conclusive, no presence of *H. pylori*, no signs of gastroesophageal reflux disease, no mucosal inflammation. NOTE: Patients <55 yr old and without any alarming symptoms can be treated without endoscopy.

LABORATORY TESTS

H. pylori: Laboratory methods include serologic tests,[1] monoclonal stool antigen, or urea breath test.

[1]Serologic testing for *H. pylori* has a low predictive value because colonization is lifelong; it can therefore determine prevalence better than incidence.

BOX 1 Causes of Dyspepsia

Luminal GI Tract
Functional dyspepsia
Chronic gastric volvulus
Chronic gastric or intestinal (mesenteric) ischemia
Food intolerance
Gastric or esophageal neoplasm
Gastric infections (cytomegalovirus, fungus, tuberculosis, syphilis)
Gastroparesis (diabetes mellitus, postvagotomy, scleroderma, chronic intestinal pseudo-obstruction, postviral, idiopathic)
GERD
Infiltrative gastric disorders (Ménétrier disease, Crohn disease, eosinophilic gastroenteritis, sarcoidosis, amyloidosis)
IBS
Parasites (*Giardia lamblia, Strongyloides stercoralis*)
PUD

Systemic Conditions
Adrenal insufficiency
Diabetes mellitus
Heart failure, myocardial ischemia
Intraabdominal malignancy
Pregnancy
Renal insufficiency
Thyroid disease, hyperparathyroidism

Medications
Acarbose
Aspirin and other NSAIDs (including COX-2 selective agents)
Colchicine
Digitalis preparations
Estrogens
Ethanol
Gemfibrozil
Glucocorticoids
Iron
Levodopa
Narcotics
Niacin
Nitrates
Orlistat
Potassium chloride
Quinidine
Sildenafil
Theophylline

Pancreaticobiliary Disorders
Biliary pain: cholelithiasis, choledocholithiasis, sphincter of Oddi dysfunction
Chronic pancreatitis
Pancreatic neoplasms

COX-2, Cyclooxygenase-2; *GERD,* gastroesophageal reflux disease; *IBS,* irritable bowel syndrome; *NSAID,* nonsteroidal antiinflammatory drug; *PUD,* peptic ulcer disease.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

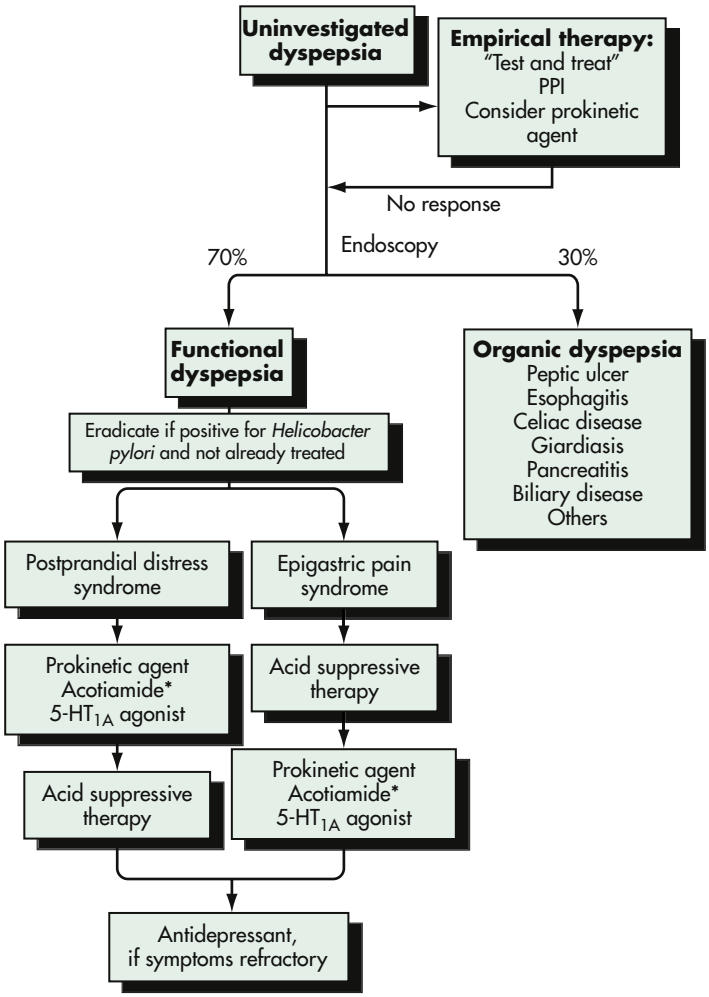

FIG. 1 An algorithm for management of patients with dyspepsia. Patients younger than age 45 to 55 yr who do not have alarm features may be treated empirically, whereas all others should be evaluated initially by endoscopy. *5-HT,* 5-hydroxytryptamine; *PPI,* proton pump inhibitor. *Not available in the U.S. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

Rx TREATMENT

ACUTE GENERAL Rx

PHARMACOLOGIC THERAPY: Primary treatment is usually initiated with proton pump inhibitors (PPIs), which can be started without performing endoscopy, especially if the patient comes from a population with low prevalence of *H. pylori* infection. If symptoms persist, a trial of antidepressants can be started. An algorithm for the management of patients with dyspepsia is described in Fig. 1.

Treatment of accompanying symptoms includes:

Predominant Symptom	Possible Etiology	Medication Recommended
Nausea	Motility dysfunction	Prokinetic agent
Bloating	Motility dysfunction	Simethicone and/or prokinetic agent
Pain	Mucosal disease or *H. pylori* infection	Antibiotic trial
Somatic complaints	Psychosocial	Psychotropic medication trial

Medication categories:

- Antacids (i.e., aluminum hydroxide, calcium carbonate)
- Gas-reducing agents, such as those containing simethicone
- H_2-receptor antagonists (i.e., cimetidine)
- PPIs (i.e., omeprazole)
- Prokinetic agents (i.e., metoclopramide, domperidone)
- Antidepressants (i.e., selective serotonin receptor inhibitors, tricyclics)
- *H. pylori* therapy/antibiotic therapy (various antibiotic regimens, usually 1 PPI) if *H. pylori* present

CHRONIC Rx

Controversy currently exists around the long-term use of PPIs. Due to the high association with psychological factors, patients with functional dyspepsia should undergo psychological intervention, even if there is good response to pharmacotherapeutic approaches.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Peppermint and caraway oil may be helpful, as well as acupuncture; however, no definitive trials have been performed.

REFERRAL

- Referral to gastroenterology if patient has alarming symptoms (such as GI bleeding, dysphagia, odynophagia, unexplained anemia, change in appetite, and weight loss) or when endoscopy is indicated—although controversy exists about the workup of younger patients
- Referral to cardiology if cardiac etiology suspected

PEARLS & CONSIDERATIONS

PREVENTION

Avoid excessive amounts of caffeine, alcohol, smoking, or long-term use of steroids and NSAIDs.

BASIC INFORMATION

DEFINITION

The term "dysphagia" is derived from the Greek words *dys* (with difficulty) and *phagia* (to eat). It is characterized by abnormal transfer of food from mouth to the stomach, which may involve the oral, pharyngeal, or esophageal stages of swallowing.

ICD-10CM CODES

D50.1	Sideropenic dysphagia
I69.091	Dysphagia following nontraumatic subarachnoid hemorrhage
I69.191	Dysphagia following nontraumatic intracerebral hemorrhage
I69.291	Dysphagia following other nontraumatic intracranial hemorrhage
I69.391	Dysphagia following cerebral infarction
I69.891	Dysphagia following other cerebrovascular disease
I69.991	Dysphagia following unspecified cerebrovascular disease
R13.10	Dysphagia, unspecified
R13.11	Dysphagia, oral phase
R13.12	Dysphagia, oropharyngeal phase
R13.13	Dysphagia, pharyngeal phase
R13.14	Dysphagia, pharyngoesophageal phase
R13.19	Other dysphagia

EPIDEMIOLOGY & DEMOGRAPHICS

- This is seen in 10% of individuals above the age of 50 yr. Its prevalence increases with advancing age.
- Nearly 12% of hospitalized patients have symptoms of dysphagia.
- Up to 30% to 60% of nursing home patients have some form of dysphagia.
- Special populations, including patients with head injury, stroke, or Parkinson disease, have 30% to 50% prevalence of oropharyngeal dysphagia.

ETIOLOGY

- Oropharyngeal:
  1. Neuromuscular causes:
     a. Stroke
     b. Parkinson disease
     c. Multiple sclerosis
     d. Myasthenia gravis
     e. Amyotrophic lateral sclerosis
     f. CNS tumors
     g. Muscular dystrophy
     h. Thyroid dysfunction
     i. Polymyositis and dermatomyositis
     j. Sarcoidosis
     k. Cerebral palsy
     l. Head trauma
     m. Metabolic encephalopathy
     n. Dementia
     o. Bell palsy
  2. Structural causes:
     a. Oropharyngeal tumors
     b. Zenker diverticulum
     c. Infection of pharynx or neck (mucositis from *Candida,* herpes, and CMV)
     d. Thyromegaly
     e. Prior surgery or radiotherapy
     f. Osteophytes and other spinal disorders
     g. Proximal esophageal webs
     h. Congenital anomalies (e.g., cleft palate)
     i. Poor dentition
- Esophageal:
  1. Neuromuscular disorders:
     a. Achalasia
     b. Diffuse esophageal spasm
     c. Nutcracker esophagus
     d. Hypertensive lower esophageal sphincter
     e. Ineffective esophageal motility
     f. Scleroderma
     g. Reflex-associated dysmotility
  2. Structural disorder:
     a. Peptic stricture
     b. Esophageal rings and webs
     c. Diverticuli
     d. Carcinoma and benign tumors
     e. Foreign bodies
     f. Vascular compression
     g. Mediastinal masses
     h. Spinal osteophytes
     i. Mucosal injury (from pills, infection, gastroesophageal reflux disease [GERD], etc.)

PATHOGENESIS

The inability to swallow is caused either by a problem in strength or coordination of the muscles required to move material from the mouth to stomach or by a fixed obstruction somewhere between the mouth and the stomach.

CLINICAL FEATURES

Oropharyngeal dysphagia (transfer dysphagia):

- The patient is unable to transfer the food bolus from the mouth to the upper esophagus. Problem arises within 2 seconds of initiating the voluntary phase of swallowing.
- Typical symptoms include drooling, spillage of food, postnasal regurgitation, difficulty in initiation of swallowing, sialorrhea, sensation of food stuck in the neck, coughing or choking during swallowing, the need to swallow repeatedly to clear food or fluid from the pharynx, dysphonia, nasal speech, hoarseness of voice, and dysarthria.
- A thorough physical examination including that of the nervous system, oral cavity, and the head/neck is very important in patients with oropharyngeal dysphagia.

Esophageal dysphagia:

- Problem usually arises several seconds after swallowing.
- Patients often complain of food being stuck in lower substernal area.
- Dysphagia to solids suggests mechanical obstruction whereas dysphagia with liquids or combination of solids and liquids favors a motility disorder.
- Neuromuscular causes result in dysphagia to both solids and liquids. Particularly, patients with achalasia tend to drink a lot of fluids while eating or apply maneuvers such as straightening the back, raising their arms over their heads, or standing to increase intraesophageal pressure to facilitate the emptying of food into the stomach.
- Oftentimes, ingestion of very cold or very hot foods precipitates the dysphagia associated with neuromuscular disorder.
- Delayed regurgitation of food, heartburn, and chest pain are usually present.
- Weight loss is usually associated with malignancy or achalasia.
- Symptoms are intermittent in patients with esophageal dysphagia from benign causes of structural obstruction or diffuse esophageal spasm. However, it is progressive in patients with peptic stricture, esophageal carcinoma, scleroderma, and achalasia.
- In patients with structural obstruction, when the luminal diameter is more than 18 to 20 mm, they are rarely symptomatic, whereas those with a diameter of less than 13 mm are nearly always symptomatic.
- These patients with esophageal dysphagia usually do not have any characteristic physical findings.

DIAGNOSIS

Laboratory Evaluation:

- CBC
- Thyroid studies
- Nutritional assessment by checking serum protein and albumin levels
- Other studies based on specific clinical conditions

Special studies:

- Oropharyngeal dysphagia
  1. Videofluoroscopy is the first test often ordered in evaluation of patients with oropharyngeal dysphagia.
  2. Double contrast modified barium swallow study (Fig. E1).
  3. Fiberoptic flexible nasopharyngeal laryngoscopy is mandatory in all cases when a structural lesion, particularly malignancy, is suspected.
  4. Pharyngeal and upper esophageal manometry (Fig. E2) is occasionally of value to predict which patients will have a favorable outcome from cricopharyngeal myotomy or dilation.
  5. Radiography of head and neck when indicated.
- Esophageal dysphagia
  1. Barium esophagography should precede upper endoscopies to identify patients at risk from potential perforation with an endoscopy and to help plan fluoroscopically guided dilation. It is often the first step in evaluating patients with dysphagia, especially if an obstructive lesion is suspected
  2. EGD
  3. Esophageal manometry is indicated if no abnormality is identified by barium study or EGD
  4. Esophageal pH monitoring in patients with suspected reflux disease
  5. Endoscopic ultrasonography
  6. Radiograph, CT, and MRI of chest

DIFFERENTIAL DIAGNOSIS (FIG. 3)

- Globus pharyngeus
- Odynophagia
- Phagophobia
- GERD

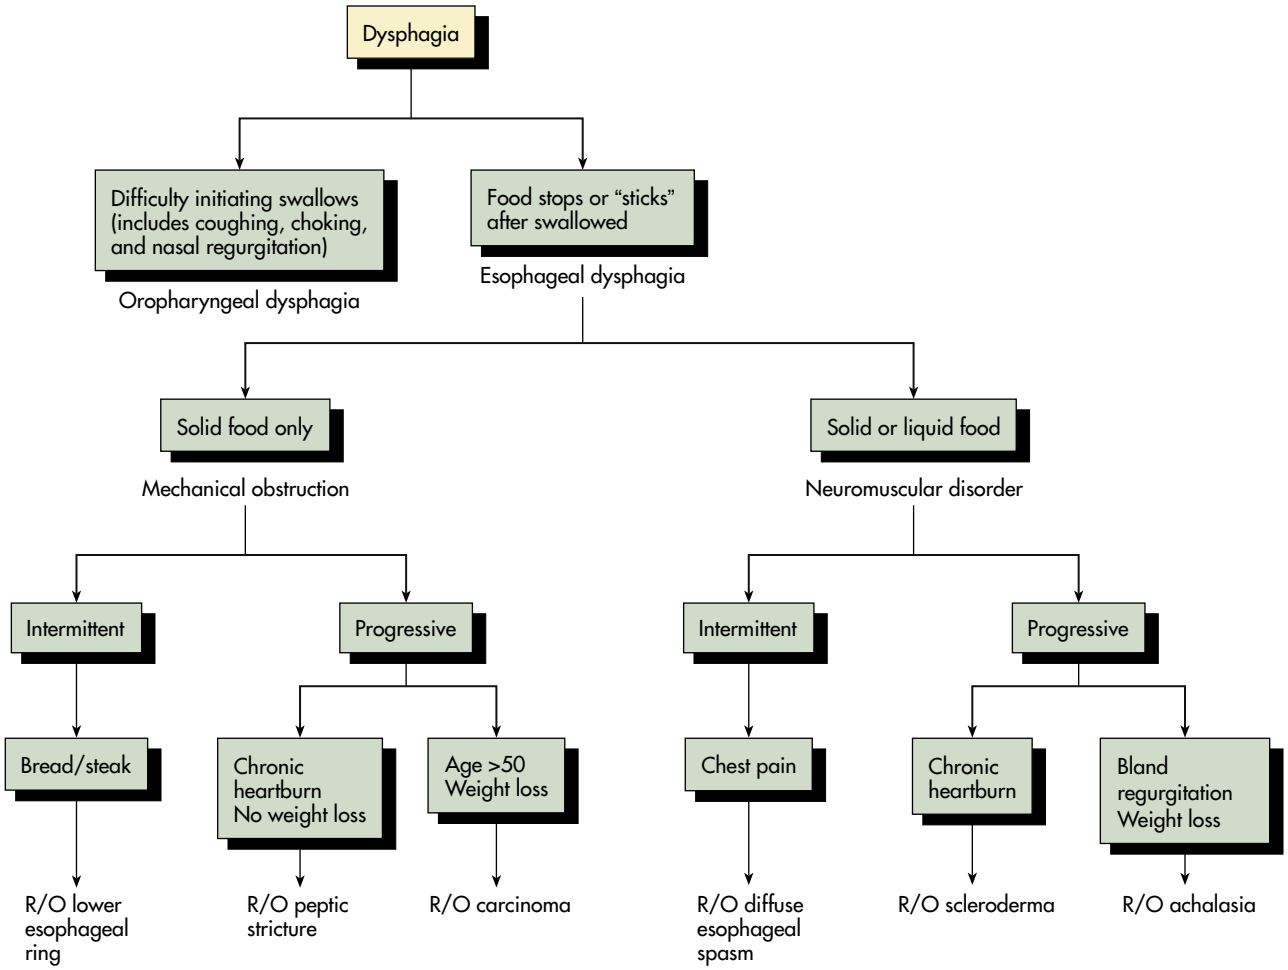

FIG. 3 Differential diagnosis of dysphagia. *R/O,* Rule out. (Modified from Andreoli TE [ed]: *Cecil essentials of medicine,* ed 7, Philadelphia, 2008, Saunders.)

Rx TREATMENT

- Treatment should be approached with the help of specialists of multiple disciplines (ENT, head and neck surgeon, radiologist, speech pathologist, physical therapist, dietitian, gastroenterologist, physical medicine and rehabilitation specialist, dentist, neurologist, etc.).
- Goal of therapy is airway protection and maintenance of nutrition.
- Alteration of food consistency, volume, and delivery rate plays a major role.
- The goal of direct therapy is to change swallowing physiology with medical treatment of primary disease, maxillofacial prosthesis, and cricopharyngeal myotomy.
- Indirect therapies include exercise programs for tongue coordination and chewing under the guidance of a speech therapist.
- Maintenance of oral feeding often requires compensatory techniques such as chin-tuck position, rotation of head to the affected side, tilting of head to the strong side, and lying on one's back or on one's side during swallowing.
- Some of the voluntary maneuvers applied include supraglottic swallow, effortful swallow, Mendelson maneuver, Shaker exercise, and the Heimlich maneuver.
- Placement of nasogastric tube, jejunostomy tube, or percutaneous endoscopic gastrotomy (PEG) tube is considered for enteral feeding when other measures fail and the patient remains at significant risk for aspiration or nutrition becomes compromised.
- Treatment of associated GERD should not be forgotten.
- Surgery for chronic aspiration may involve tracheostomy, medialization, laryngeal suspension, laryngeal closure, and/or laryngotracheal separation-diversion.
- Other measures include esophageal dilation removal of foreign body, esophageal resection, chemotherapy, radiotherapy, endoscopic ablation of tumor, photodynamic therapy, esophageal prosthesis/stents, diverticulectomy, intrasphincteric injection of botulinum toxin, surgical myotomy, and others. Smooth muscle relaxants such as nitrates and calcium channel blockers have been used to effectively treat patients with diffuse esophageal spasm and nutcracker esophagus.
- Several scales have been suggested to determine patients' functional outcome. One of them is the "Swallowing Rating Scale."

COMPLICATIONS

- Dehydration
- Malnutrition
- Aspiration pneumonia
- Airway obstruction
- Death resulting from pulmonary complications

PROGNOSIS

- Depends on the etiology.
- Nursing home patients with oropharyngeal dysphagia and a history of aspiration have an approximately 45% mortality rate over 1 yr.
- All patients, especially the elderly, should take their medications with a full glass of water while in upright position well before bedtime.
- Dysphagia should be considered an alarm symptom, indicating the need for immediate evaluation.

PATIENT EDUCATION

Elderly patients with dysphagia should not attribute their symptoms to aging.

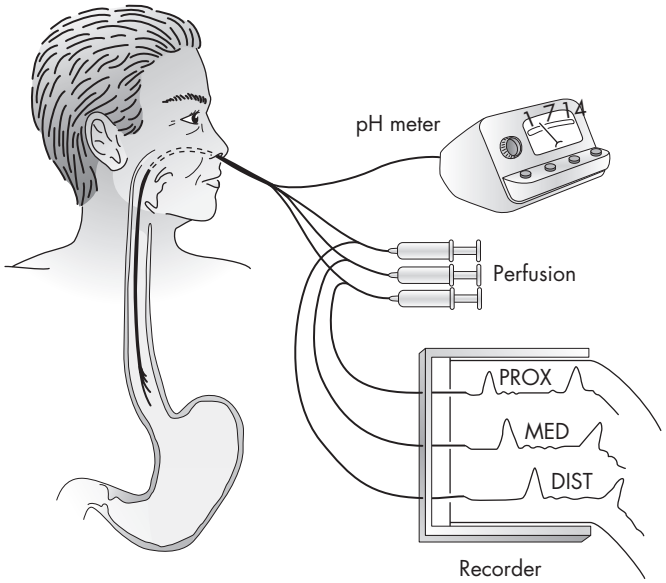

FIG. E2 Combined manometric-pH recording system used in the evaluation of esophageal function. The triple-lumen perfused recording catheter measures intraluminal pressures from three levels in the esophagus. Measurements are made in terms of centimeters from the nostrils to the proximal opening of the recording catheter *(PROX).* The medial catheter *(MED)* records pressures 5 cm distal to the proximal opening and the distal catheter *(DIST)* 5 cm below this. The intraesophageal pH electrode is used to document gastroesophageal reflux. (From Townsend CM et al: *Sabiston textbook of surgery,* ed 17, Philadelphia, 2004, Saunders.)

BASIC INFORMATION

DEFINITION

Dystonia refers to a group of disorders characterized by involuntary muscle contractions (sustained or spasmodic) that lead to abnormal body movements or postures. Dystonia can be generalized or focal, of early (<20 yr) or late onset, and primary or secondary.

SYNONYMS

Blepharospasm
Oromandibular (orofacial) dystonia
Spasmodic (limb or axial) dystonia
Torticollis
Writer's cramp

ICD-10CM CODES

G24	Dystonia
G24.1	Idiopathic familial dystonia
G24.0	Drug induced dystonia
G24.3	Spasmodic torticollis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Estimated at 1 in 3000 persons.
PREDOMINANT SEX: Cervical dystonia has a 3:2 female preponderance.
PREDOMINANT AGE:

- Onset of focal cervical dystonia is usually in the fifth decade.
- Hereditary forms may have an onset in childhood or adulthood and tend to be more severe.

GENETICS: Autosomal-dominant, autosomal-recessive, and X-linked forms of dystonia have been identified. Metabolic conditions in which dystonia is a feature can be inherited or, more frequently, caused by sporadic mutations.

CLINICAL PRESENTATION

Focal dystonias produce abnormal sustained muscle contractions in a single region of the body. Most frequently encountered examples include:

- Neck (***torticollis***): Most commonly affected site with a tendency for the head to turn to one side. Jerky or tremulous movements of the head might occur, which can resemble essential tremor. Patients find that lightly touching the face can reduce the dystonia; this is known as a "sensory trick" or "*geste antagoniste.*"
- Eyelids (***blepharospasm***): Involuntary closure of the eyelids that leads to excessive eye blinking (Fig. E1), sometimes with persistent eye closure (Fig. E2) and functional blindness. Stress and bright sunlight can be triggers for patients prone to this condition.
- Mouth (***oromandibular dystonia***): Involuntary contraction of muscles of the mouth, tongue, or face, resulting in difficulty speaking or swallowing.
- Hand (***writer's cramp***) (Fig. E3). The act of writing is the trigger for this form of focal dystonia. Task-specific dystonias can also occur with other activities, such as playing a musical instrument.
- Spasmodic dysphonia: A dystonia of the vocal cords that results in a strained-sounding voice.
- Isolated foot dystonia: Very rare and may suggest an underlying parkinsonian disorder or brain structural abnormality.

Generalized dystonia affects multiple areas of the body and can lead to marked joint deformities.

ETIOLOGY

- Exact pathophysiology of primary dystonia is unknown but believed to involve abnormalities of basal ganglia. Specifically, reduced and abnormal patterns of neuronal activity in the basal ganglia result in disinhibition of the motor thalamus and cortex, leading to abnormal movement.
- Numerous genetic forms of dystonia exist, some in the context of underlying metabolic disorders. Genetic testing is available but is usually reserved for individuals with a family history of dystonia.
- Secondary dystonia results from central nervous system (CNS) disease of the basal ganglia (stroke, demyelination, hypoxia,

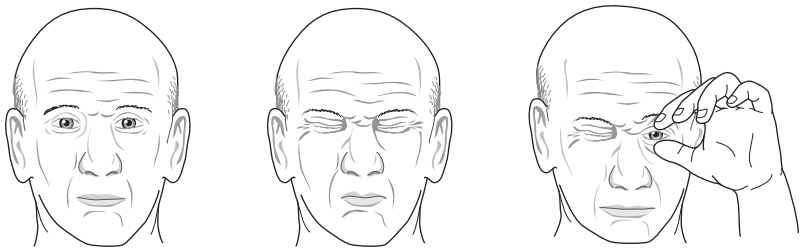

FIG. E1 This man with blepharospasm has repeated, unprovoked closure of both eyelids lasting about 5 seconds at a time due to involuntary contractions of his orbicularis oculi muscles. Because the spasms block his vision, he often resorts to prying open his eyelids. In contrast to eyelid closure as a tic, the closures in blepharospasm are longer, more forceful, and not preceded by an urge to close the eyes. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

FIG. E3 Focal dystonia of the distal right arm. (From Goldman L, Ausiello D [eds]: *Cecil textbook of medicine,* ed 22, Philadelphia, 2004, Saunders.)

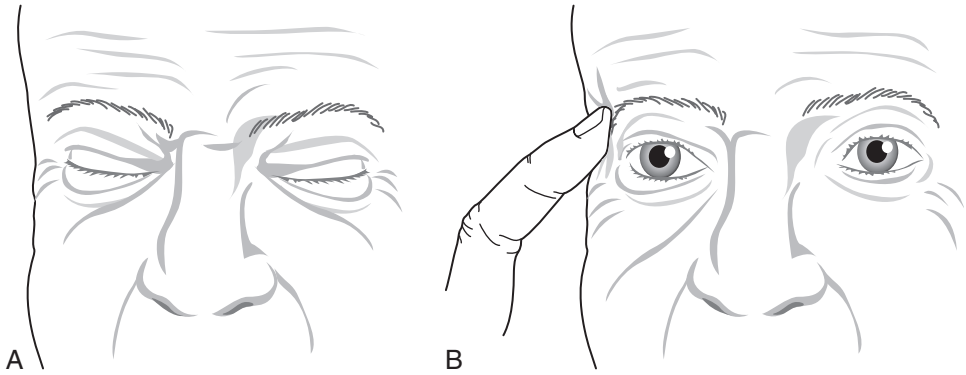

FIG. E2 A, During periods of blepharospasm, this man cannot open his eyelids. He attempts, perhaps unconsciously, to open them by contracting his frontalis muscle. **B**, He has instinctively learned that the sensory trick of lightly touching one eyebrow (a *geste antagoniste*) suppresses the spasms briefly. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

trauma), Huntington disease, Wilson disease, Parkinson syndromes, and lysosomal storage diseases.
- Acute dystonia can occur with drugs that block dopamine receptors, such as phenothiazines or butyrophenones.
- Tardive dyskinesia and tardive dystonia can result from long-term treatment with antiemetics (e.g., phenothiazines), antipsychotics (e.g., haloperidol), levodopa, anticonvulsants, or ergots.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Drug effects
- Parkinson disease
- Progressive supranuclear palsy
- Wilson disease
- Huntington disease
- Table E1 describes selected causes of primary and secondary dystonia in childhood

WORKUP

History (family history, birth history, trauma, medication use, age of onset, and temporal pat-

TABLE E1 Selected Causes of Primary and Secondary Dystonia in Childhood

Diagnosis	Additional Clinical Features
Aicardi-Goutieres syndrome	Encephalopathy, developmental regression Acquired microcephaly Sterile pyrexias Lesions on the digits, ears (chilblain) Epilepsy CT: Calcification of the basal ganglia
Alternating hemiplegia of childhood	Episodic hemiplegia/quadriplegia Abnormal ocular movements Autonomic symptoms Epilepsy Global developmental impairment Environmental triggers for spells
Aromatic amino acid decarboxylase deficiency (AADC)	Developmental delay Oculogyric crises Autonomic dysfunction Hypotonia
ARX gene mutation (X-linked)	Male Cognitive impairment Infantile spasms, epilepsy Brain malformation
Benign paroxysmal torticollis of infancy	Episodic Cervical dystonia only Family history of migraine
Complex regional pain syndrome	Lower limb involvement Prominent pain
Dopa-responsive dystonia (DRD)	Diurnal variation
Drug-induced dystonia	
Dystonia-deafness optic neuropathy syndrome	Sensorineural hearing loss in early childhood Psychosis Optic atrophy in adolescence
DYT1 dystonia	Lower limb onset followed by generalization
Glutaric aciduria type 1	Macrocephaly Encephalopathic crises MRI: Striatal necrosis
GM1 gangliosidosis type 3	Short stature, skeletal dysplasia Orofacial dystonia Speech/swallowing disturbance Parkinsonism MRI: Putaminal hyperintensity
Huntington disease (HD)	Parkinsonism Epilepsy Family history of HD
Kernicterus	Jaundice in infancy Hearing loss Impaired upgaze Enamel dysplasia MRI: Hyperintense lesions in the globus pallidus
Leigh syndrome	Motor delays, weakness, hypotonia Ataxia, tremor Elevated lactate MRI: Bilateral symmetric hyperintense lesions in the basal ganglia or thalamus
Lesch-Nyhan syndrome (X-linked)	Male Self-injurious behavior Hypotonia Oromandibular dystonia, inspiratory stridor Oculomotor apraxia Cognitive impairment Elevated uric acid
Myoclonus dystonia	Myoclonus Head, upper limb involvement
Neuroacanthocytosis	Oromandibular and lingual dystonia
Neurodegeneration with brain iron accumulation	Cognitive impairment Retinal pigmentary degeneration, optic atrophy
Niemann-Pick type C	Hepatosplenomegaly Hypotonia Supranuclear gaze palsy Ataxia, dysarthria Epilepsy Psychiatric symptoms
Rapid onset dystonia parkinsonism (DYT12)	Acute onset Distribution face>arm>leg Prominent bulbar signs
Rett syndrome	Female Developmental regression following a period of normal development Stereotypic hand movements Acquired microcephaly Epilepsy
Spinocerebellar ataxia 17 (SCA17)	Ataxia Dementia, psychiatric symptoms Parkinsonism
Tics	Stereotyped movements Premonitory urge, suppressible
Tyrosine hydroxylase deficiency	Infantile encephalopathy, hypotonia Oculogyric crises, ptosis Autonomic symptoms Less diurnal fluctuation than DRD

CT, Computed tomography; *MRI*, magnetic resonance imaging.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

tern), physical examination to determine associated features (weakness, myoclonus, tremor) and to determine pattern of dystonia—focal (single body region), segmental (two or more body contiguous body regions), multifocal (two or more noncontiguous body regions), generalized (involving the trunk and at least two other sites), or hemidystonia (involving more regions but restricted to one body side).

LABORATORY TESTS

- Usually not helpful for diagnosis
- Serum ceruloplasmin if Wilson disease is suspected
- Genetic testing (*DYT* gene mutations, inborn errors of metabolism, or mitochondrial disease) if indicated, based on family history
- Comprehensive toxicology screen indicated if causative drugs suspected (dopamine-blocking agents) and history unavailable

IMAGING STUDIES

- Primary dystonias are generally not associated with structural CNS abnormalities. CT scan or MRI of brain if a CNS lesion is suspected as a cause of secondary dystonia.
- Electrophysiologic testing can provide diagnostic support for the diagnosis, but dystonia is a clinical diagnosis.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Heat, massage, physical therapy to relieve pain.
- Splints to prevent contractures.
- "Sensory trick" (*geste antagoniste*) involves lightly touching the affected body part; this can relieve the discomfort of dystonia.

ACUTE GENERAL Rx

- For acute dystonic reactions to phenothiazines/butyrophenones, use diphenhydramine 50 mg IV or benztropine 2 mg IV.
- For patients presenting with subacute or chronic dystonia, a trial of L-dopa can be useful in distinguishing dopa-responsive dystonia from other causes.

CHRONIC Rx

- For treatment of drug-induced dystonia, slowly withdraw offending agents (antiemetics, antipsychotics most commonly).
- For generalized dystonia, a trial of carbidopa/levodopa may be beneficial and diagnostic of dopa-responsive dystonia.
- Trihexyphenidyl and tetrabenazine are the mainstays of medical treatment for generalized dystonias not responsive to dopa.
- Diazepam, clonazepam, or baclofen may be helpful as adjunctive agents.
- Injections of botulinum toxin into the affected muscles are the standard treatment for focal or multifocal dystonias but cannot be used for generalized dystonia. The mechanism of action involves blockage of the neuromuscular junction acetylcholine transmission.
- Surgical procedures, most commonly deep brain stimulation of the internal globus pallidus, may be helpful for severe, refractory cases.
- Intrathecal baclofen can be useful for spastic or truncal dystonia.

DISPOSITION

Spontaneous remission of focal cervical dystonia can occur, but dystonia is generally progressive, and pharmacologic therapy is often ineffective.

REFERRAL

- Neurology (movement disorders) and/or neurosurgery for severe or refractory cases.
- Physical therapy for maintaining flexibility.

PEARLS & CONSIDERATIONS

COMMENTS

- Avoid triggers/exacerbating factors.
- Early physical therapy and splinting to prevent contractures.
- Consider botulinum toxin injections early in the course.
- Consider deep brain stimulation surgery for severe or refractory dystonia and for focal dystonias.

BASIC INFORMATION

DEFINITION

An early repolarization pattern (ERP) in a QRS complex with a duration <120 ms, a peak J point elevation of ≥0.1 mV in two or more contiguous leads **excluding** leads V_1-V_3, with a notch or slur noted in the end of the QRS complex at the downslope of a prominent R wave (Fig. E1). This notch must be above the baseline T-P segment (Fig. E2). Previously thought to be benign, the pattern has been noted in higher prevalence in patients with idiopathic ventricular fibrillation (VF). Recently it has been cited as a predictor of symptoms in the setting of long QT syndrome, as well as a predictor of arrhythmic events in patients with structural heart disease.

SYNONYMS

Early repolarization syndrome—sudden cardiac arrest in a patient with ERP
J point elevation
Persistent juvenile pattern

ICD-10CM CODES

R94.310	Abnormalities ECG—Abnormalities of ST segment
R00.9	Unspecified abnormalities of heart beat
I49.9	Cardiac arrhythmia unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The clinical entity "early repolarization pattern" is commonly asymptomatic; therefore, the true incidence of the pattern is difficult to definitively establish. In one comparison of patients with idiopathic ventricular fibrillation (VF) vs. young athletes vs. age-matched controls, the presence of ERP, defined as J point elevation >1.0 mm, in idiopathic VF patients was 31.1% in any lead, 17.8% in inferior leads, 11.1% in leads I and aVL, and 6.7% in leads V_4 to V_6. For comparison, the incidence in age-matched controls was 8.9% in any lead, 6.5% in inferior leads, 0% in leads I and aVL, and 4.9% in leads V_4 to V_6.

PREDOMINANT SEX: J point elevation >1 mm was documented significantly higher in males vs. females.

GENETICS: The mode of transmission and the genetic basis of the syndrome are unclear. An autosomal dominant pattern of inheritance of the *KCNJ8* gene, which has been associated with sporadic cases, has been shown. The prognostic value of the inheritance pattern is not known.

RISK FACTORS: Male sex, younger age, lower systolic blood pressure, higher Sokolow-Lyon index, and lower Cornell voltage have been shown to be associated with the presence of the early repolarization pattern. The early repolarization pattern carries an increased risk for future arrhythmic death. This is considered to be higher in the setting of a downsloping ST segment.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The physical exam will not show any findings specific for early repolarization. Rather, the clinical presentation is well documented in patients resuscitated from cardiac arrest. This is particularly shown in a pattern in which the early repolarization is seen in the inferior and/or the lateral leads but not in the precordial leads. The pattern has been shown to have an intermittent pattern of expression.

ETIOLOGY

J point elevation is considered to be the electrocardiographic representation of a voltage gradient between different layers from the epicardium to the endocardium. The epicardium has a relatively higher density of transient outward potassium current (I_{TO}), when compared to the endocardium, resulting in a prominent notch in phase I of the action potential. The Brugada syndrome is considered an extreme version of this phenomenon, where a loss of function mutation in the *SCN5A* gene results in loss of phase II in the action potential, causing marked J point and ST segment elevation, allowing for polymorphic ventricular tachycardia.

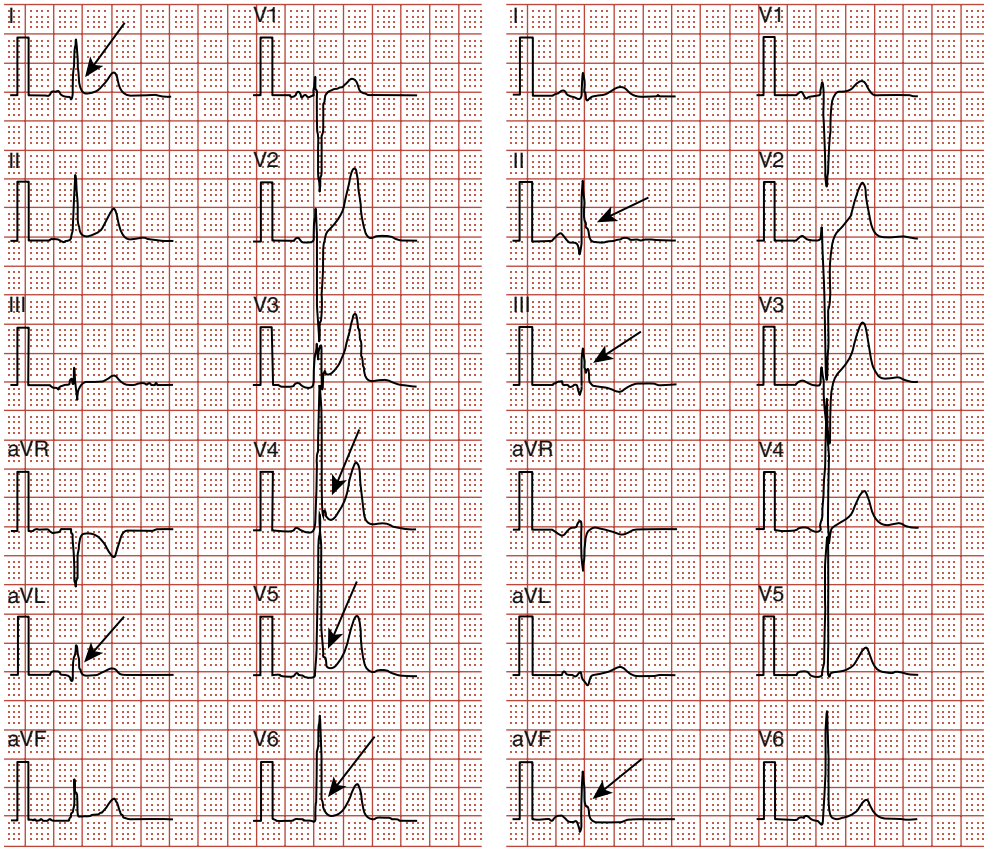

FIG. E1 A, Notching in lead V_4 progressing to slurring in V_6, I, aVL. **B,** Notching in lead III, aVF and slurring in lead II. aVF, Augmented vector foot; aVL, augmented vector left; aVR, augmented vector right. (From Macfarlane PW et al: The early repolarization pattern: a consensus pattern, *J Am Coll Cardiol* 66:470-477, 2015.)

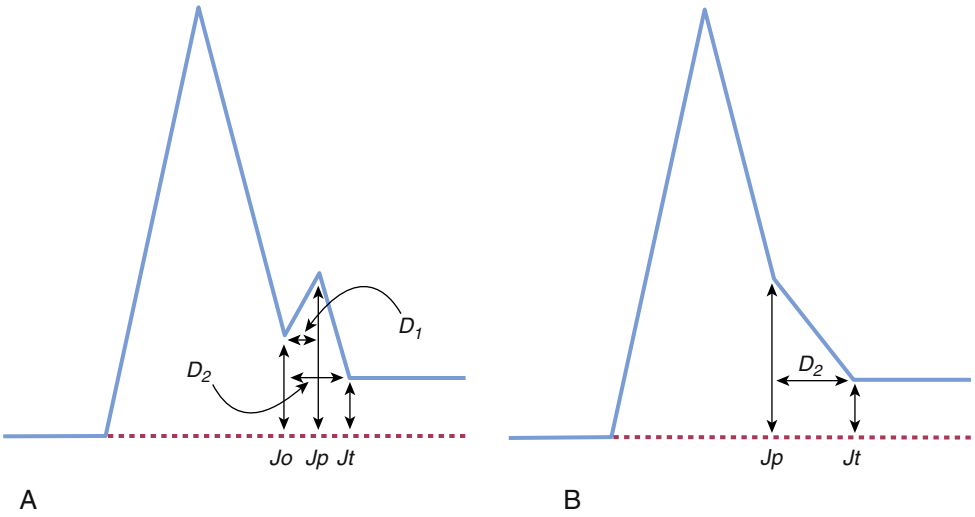

FIG. E2 A, Illustration of the amplitudes J onset (Jo), J peak (Jp), and J termination (Jt) as well as durations D1 and D2 in relation to an end QRS notch, as defined previously. **B,** Illustration of Jp and Jt as well as D2 in relation to an end QRS slur. (From Macfarlane PW et al: The early repolarization pattern: a consensus pattern, *J Am Coll Cardiol* 66:470-477, 2015.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Benign vs. malignant early repolarization
- Brugada syndrome
- Persistent juvenile pattern

WORKUP

- Primarily guided by the clinical scenario. In a patient where the early repolarization pattern is an incidental finding (Figs. E3 and E4), detailed family history for sudden cardiac death is indicated
- However, should the pattern be identified in the setting of a cardiac arrest, then the workup would be directed to identification of potentially reversible causes
  1. Basic metabolic panel
  2. Echocardiogram
  3. Ischemic evaluation—noninvasive stress testing vs. left heart catheterization
  4. Electrophysiology testing
  5. ICD implant for secondary prevention of sudden cardiac death if no reversible cause is identified

LABORATORY TEST

- BMP
- Thyroid function studies

IMAGING STUDIES

Echocardiogram

TREATMENT

No treatment is indicated in the case of the early repolarization pattern. In the setting of early repolarization syndrome with sudden cardiac death, the treatment would be that of sudden cardiac death as detailed under "Workup."

REFERRALS

Cardiology referral should be obtained, particularly in the setting of syncope, nonsustained ventricular tachycardia, or cardiac arrest.

PEARLS & CONSIDERATIONS

COMMENTS

The early repolarization pattern has previously been considered a benign pattern; however, the body of evidence suggests it to be a risk factor for sudden cardiac death. Therefore, all patients with early repolarization, particularly with risk factors or an isolated pattern in the inferior leads, merit a detailed evaluation.

PREVENTION

BASIC INFORMATION

DEFINITION

Echinococcosis is a chronic infection caused by the larval stage of several animal cestodes (tapeworms) of the genus *Echinococcus* after ingestion of parasite eggs.

SYNONYMS

Hydatid disease, hydatidosis, cystic echinococcosis (CE)
Alveolar echinococcosis (AE)
Polycystic echinococcosis

ICD-10CM CODES	
B67.8	Echinococcosis, unspecified, of liver
B67.90	Echinococcosis, unspecified
B67.99	Other echinococcosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Seen primarily in foreign-born patients, but local transmission of CE can occur in southwestern U.S., California, and Alaska. Found in areas where humans live in close proximity to dogs and livestock slaughtering. AE is found where humans have contact with wild foxes or coyotes, predominantly in the north central region of the U.S.
PEAK INCIDENCE: Presumed to be acquired in childhood or early adulthood in most cases, although prevalence increases with age.
PREVALENCE (IN U.S.): Prevalence in the U.S. is unknown.
PREDOMINANT SEX: Globally, women are more often affected by cystic echinococcosis than men. This higher prevalence in women is felt to be related to domestic activities that bring them in closer contact with dogs.
PREDOMINANT AGE: 0 to 50 yr of age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- There are two predominant forms: Cystic echinococcosis (hydatidosis), caused primarily by *E. granulosus* and to a lesser extent other species, and alveolar echinococcosis, caused by *E. multilocularis.* Rarely, polycystic/unicystic echinococcus occurs in humans caused by *E. vogeli* and *E. oligarthrus.*
- Uncomplicated cystic echinococcosis is generally asymptomatic but may cause mass effect with signs of an enlarging mass lesion in a visceral site such as the liver, lungs, kidneys, bone, or CNS.
- Occasional cyst rupture may cause allergic manifestations such as urticaria, angioedema, or anaphylaxis that bring the patient to medical attention. Additionally, in the case of rupture, secondary bacterial infection may occur, or fistulas may develop (e.g., cystobiliary).
- Incidental discovery of cysts by abdominal or thoracic imaging studies performed for other reasons.
- Alveolar echinococcosis may mimic cirrhosis or liver cancer with upper abdominal discomfort, weight loss, and weakness. Rarely, it can spread to other tissues, including the brain.

ETIOLOGY

- There are several recognized species of *Echinococcus,* of which at least seven cause human disease: *E. granulosus sensu stricto, E. equinus, E. ortleppi, E. canadensis, E. multilocularis, E. oligarthrus,* and *E. vogeli.*
  1. Predominantly *E. granulosus* is the cause of cystic echinococcosis.
  2. *E. multilocularis* is the cause of alveolar echinococcosis.
- The disease is transmitted to humans by infected canines (domestic or wild dogs, wolves, foxes), which are the definitive hosts, and is seen most commonly in livestock-producing areas of the Middle East, Africa, Australia, New Zealand, Europe, and the Americas, including the southwestern U.S., whereby sheep, goats, camels, or cattle serve as intermediate hosts to humans. Humans are incidental hosts and do not play a role in the transmission cycle.
- The adult tapeworm resides in the small intestine of the canine definitive hosts. Eggs are then shed in the feces of infected canines; human infection occurs by ingestion of viable eggs in contaminated food from intermediate hosts or direct fecal-oral transmission.
- After ingestion of the eggs by intermediate hosts or humans, eggs hatch and release oncospheres, which migrate through intestinal mucosa to definitive organs and develop into enlarging fluid-filled cysts known as hydatid cysts (metacestode) (Fig. E1). The cyst is acellular and is surrounded by fibroblasts and lymphocytic infiltrate (Fig. E2).
- It is common in many areas of the world, especially the Middle East.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cystic neoplasms (see Table E1)
- Abscess (amebic or bacterial)
- Congenital polycystic disease

WORKUP

- Antibody assay (with limitations in sensitivity and specificity).
- Imaging study (CT scan [Fig. E3], ultrasonography).
- Classification (Fig. E4): Table E2 describes the World Health Organization Informal Working Group on Echinococcosis classification of hepatic echinococcal cysts.

FIG. E1 Hydatid cysts removed surgically. (From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, Saunders.)

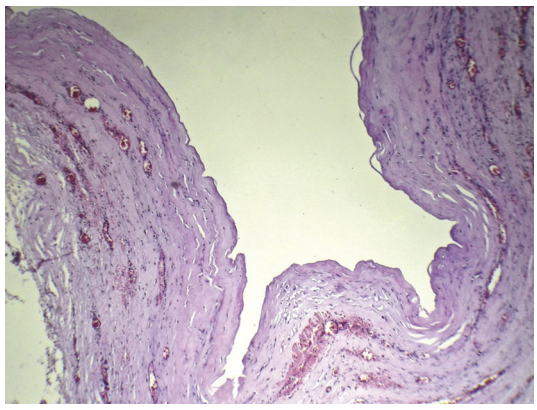

FIG. E2 Echinococcosis. The cyst is acellular and is surrounded by fibroblasts and lymphocytic infiltrate. (From Prieto-Granada CN et al: Skin infections. In Kradin RL [ed], *Diagnostic pathology of infectious disease*, Philadelphia, 2010, Elsevier, pp 519–616.)

TABLE E1 Hepatic Cyst Disease: Differential Features on Imaging Studies

Characteristics	Hydatid Cyst	Congenital Cyst	Cystadenoma
Configuration	Cyst within cyst	Single or multiple ± septations	Single ± septations
Wall character	Thick, uniform ± calcification	Thin, uniform	Mural nodules
Cyst contents	Daughter cysts hydatid sand	Low density	Low density

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

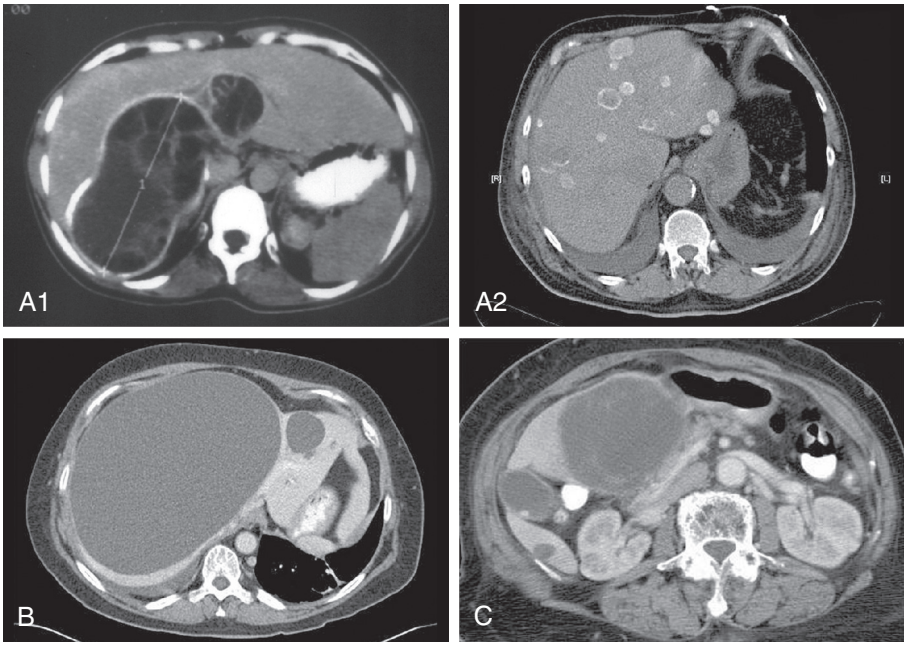

FIG. E3 A comparison of computed tomography scans. A, Hepatic echinococcal cysts. **B,** Congenital cyst. **C,** Cystadenoma. For echinococcal cyst. **A1** demonstrates a single cyst with calcification and daughter cyst caused by *E. granulosa*. **A2** shows multiple small cysts characteristic of *E. multilocularis* infection. (Courtesy of Barbara M. Kadell, MD, Professor of Radiology, David Geffen School of Medicine at University of California, Los Angeles. From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.)

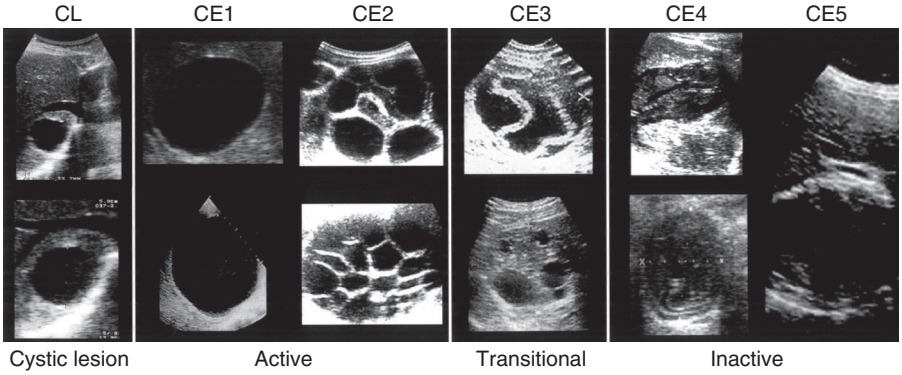

FIG. E4 World Health Organization (WHO) Informal Working Group on Echinococcosis standardized ultrasound classification of cystic echinococcosis. *CL* lesions are cystic lesions lacking a distinct wall and may have other diagnoses. *CE1* lesions are cystic lesions with a visible wall that may demonstrate protoscoleces ("hydatid sand"). *CE2* lesions include internal septation. *CE3* lesions may be detached from the wall or have daughter cysts with internal thickening. *CE4* lesions are heterogeneous lesions with degeneration. *CE5* lesions show thick calcification. (From Goldman L, Schafer AI: *Goldman's Cecil medicine*, ed 24, Philadelphia, 2012, Saunders.)

- Histologic examination of cyst or contents obtained by aspiration or resection (if possible) to confirm diagnosis, although this is rarely indicated.

LABORATORY TESTS

Antibody assays (ELISA or Western blot) available through CDC: 80% to 100% sensitive and 88% to 96% specific for liver cysts, but less accurate for cysts in other sites, such as lung. A PCR assay is now available for problematic cases. Eosinophilia is not consistently seen and thus is not a reliable indicator.

IMAGING STUDIES

Ultrasonography, CT, and MRI:

- All are extremely sensitive for the detection of cysts, especially in the liver.
- All lack specificity and are inadequate to establish the diagnosis of echinococcosis with certainty.

Rx TREATMENT

ACUTE GENERAL Rx

- There are four treatment modalities: Percutaneous intervention, surgery, chemotherapy, and observation. Expert consultation is recommended, and treatment decisions are based on size and appearance of the cysts (Fig. E4).
- Albendazole 400 mg PO bid followed by percutaneous aspiration-injection-reaspiration (PAIR) for uncomplicated larval cysts. It consists of puncture (P) and needle aspirate (A) of cyst content followed by inspiration (I) of hypertonic saline (15% to 30%) or absolute alcohol, waiting 20 to 30 minutes, then re-aspirating (R) with final irrigation. Albendazole is continued for 28 days. Cure rate is 96%.
- Surgical resection: Cure rate 90%.
- Treatment course depends on presentation and clinical response, with chemotherapy alone often given continuously for months to years. Alternatives to albendazole include mebendazole and praziquantel alone or in combination with mebendazole.

DISPOSITION

- Long-term follow-up is necessary following surgical or medical therapy because of the potential for late relapse.
- Antibody assays and imaging studies are repeated every 6 to 12 mo for several yr following successful surgical or medical therapy.

REFERRAL

All patients should be referred for expert consultation.

TABLE E2 WHO-IWGE Classification of Hepatic Echinococcal Cysts

Type of Cyst	Status	Ultrasound Features	Remarks
CL	Active	Signs not pathognomonic, unilocular, no cyst wall	Usually early stage, not fertile; differential diagnosis necessary
CE 1	Active	Cyst wall, hydatid sand	Usually fertile
CE 2	Active	Multivesicular, cyst wall, rosettelike	Usually fertile
CE 3	Transitional	Detached laminated membrane, "water lily" sign, less round, decreased intracystic pressure	Starting to degenerate, may produce daughter cyst
CE 4	Inactive	Heterogeneous hypoechogenic or hyperechogenic degenerative contents; no daughter cyst	Usually no living protoscoleces; differential diagnosis necessary
CE 5	Inactive	Thick, calcified wall, calcification partial to complete; not pathognomonic but highly suggestive of diagnosis	Usually no living protoscoleces

CE, Cystic echinococcosis; *CL*, cystic lesion; *WHO-IWGE,* World Health Organization Informal Working Group on Echinococcosis.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

PEARLS & CONSIDERATIONS

COMMENTS

Cyst resection, if indicated, should be performed by surgeons experienced with this procedure.

BASIC INFORMATION

DEFINITION

Eclampsia is the occurrence of seizures or coma in a woman with signs or symptoms of preeclampsia, occurring at >20 wk of gestation or <48 hr postpartum. Atypical eclampsia occurs at <20 wk of gestation or as much as 23 days postpartum.

SYNONYMS

Toxemia
Seizures of pregnancy

ICD-10CM CODES

O15.00	Eclampsia in pregnancy, unspecified trimester
O15.02	Eclampsia in pregnancy, second trimester
O15.03	Eclampsia in pregnancy, third trimester
O15.1	Eclampsia in labor
O15.2	Eclampsia in the puerperium
O15.9	Eclampsia, unspecified as to time period

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: One case per 1500 to 3000 pregnancies; 2% to 4% of those with preeclampsia; one large Australian series found 8.6 cases per 10,000 live births.
GENETICS: Increased incidence with a first-degree relative (sister or mother) having had eclampsia.
RISK FACTORS: Multifetal gestation (3.6% in twin gestation), molar pregnancy, nonimmune hydrops fetalis, uncontrolled hypertension, preexisting hypertension, renal disease, systemic lupus, and existing heart disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Seizure often begins as facial twitching, then spreads to generalized tonic-clonic state, with cessation of respiration followed by a postictal period of amnesia, agitation, and confusion.
- The most common symptoms preceding eclampsia are headache (80%), visual disturbance (45%), and epigastric pain (20%). Seventeen percent are completely asymptomatic prior to seizure.
- Forty percent have severe hypertension, 40% have mild to moderate hypertension, and 20% are normotensive.
- Generalized edema with rapid weight gain (>2 lb/wk) may precede eclampsia.

ETIOLOGY

Common pathway relates to abnormalities in autoregulation of cerebral blood flow. This may involve transient vasospasm, ischemia, cerebral hemorrhage, and edema occurring by a mechanism involving hypertensive encephalopathy, decreased colloid osmotic pressure, and prostaglandin imbalance.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Preexisting seizure disorder
- Metabolic abnormalities (hypoglycemia, hyponatremia, hypocalcemia)
- Substance abuse
- Head trauma, infection (meningitis, encephalitis)
- Intracerebral bleeding or thrombosis
- Amniotic fluid embolism
- Space-occupying brain lesions or neoplasms
- Pseudoseizure
- Hypertensive encephalopathy
- Venous or arterial thrombosis, arterial embolism
- Posterior reversible encephalopathy syndrome (often seen in eclampsia)
- Vasculitis, angiopathy
- Thrombotic thrombocytopenic purpura

WORKUP

- Rule out other causes of seizures during pregnancy.
- Atypical presentations such as prolonged postictal state; status epilepticus; gestational age <20 wk or >48 hr postpartum; or signs of meningitis, substance abuse, or severe uncontrolled hypertension should prompt a search for other seizure etiologies.

LABORATORY TESTS

- Proteinuria: Severe (49%), mild to moderate (29%), absent (22%)
- HCT: Elevated as a result of hemoconcentration
- Platelet count: Decreased; LFTs elevated in HELLP syndrome (hemolysis, elevated liver enzymes, and low platelet count)
- BUN and creatinine: Elevated with renal involvement
- Serum electrolytes, glucose, calcium, toxicology profile: Rule out other causes of seizures
- ABG: Maternal acidemia and hypoxia

IMAGING STUDIES

- CT scan or MRI indicated in atypical presentation, suspected intracerebral bleeding, or focal neurologic deficit.
- Over 90% of patients will have findings consistent with posterior reversible encephalopathy syndrome on MRI.
- There are other abnormal findings, including cerebral edema, hemorrhage, and infarction, in 50% of patients.

TREATMENT

ACUTE GENERAL Rx

- Maintain airway, adequate oxygenation, and IV access.
- Fetal resuscitation involving maternal oxygenation, left lateral positioning, and continuous fetal heart rate monitoring is needed.
- Magnesium sulfate is the drug of choice. Give magnesium sulfate 6 g IV load over 20 min, then 2 g/hr maintenance, for treatment and recurrent seizure prophylaxis. Adjust maintenance dose for renal insufficiency. If there is no IV access, may give 10 g IM (5 g to each buttock). If repeated convulsions, may give an additional 2 g IV over 3 to 5 min. Approximately 10% to 15% of patients will have a second seizure after initial loading dose. Clinical signs of progressive Mg^{2+} toxicity, such as loss of reflexes, should also be followed. If magnesium toxicity is suspected, check magnesium level (therapeutic range 4 to 7 mEq/L). If serum level >9.6 mg/dl, stop infusion. Respiratory and cardiac arrest occur at extremely high magnesium levels. Antidote for toxicity is calcium gluconate 10 ml of 10% solution. Phenytoin has been used as an alternative in patients in whom magnesium sulfate is contraindicated (e.g., heart block, myasthenia gravis).
- Give sodium amobarbital 250 mg IV over 3 min for persistent seizures not responsive to magnesium sulfate.
- Treat BP >160 mm Hg systolic or BP >110 mm Hg diastolic with either hydralazine 5 to 10 mg IV, then 10 mg, then 10 mg every 20 minutes to a maximum of 20 mg; or labetalol hydrochloride 20, 40, 80 mg IV, escalating the dose every 10 minutes to maximum total dose of 300 mg; or nifedipine 10 - 20 mg orally every 20 minutes can be used for acute blood pressure control, if no IV access, to a total dose of 180 mg/day. If maximum dose of one medication is reached, add an additional medication to reach goal of BP 140 to 150/90 to 100 mm Hg.
- Evaluate patient for delivery.

CHRONIC Rx

- The first priority is stabilization of the mother in terms of adequate oxygenation, hemodynamics, and laboratory abnormalities, such as associated coagulopathies.
- Cervical status and gestational age should be assessed. If unfavorable cervix and <30 wk of gestation, consider C-section; otherwise consider induction.
- Give antenatal corticosteroids if 24 to 34 wks' gestation. Consider antenatal corticosteroids if 34 to 36-6/7 wks' gestation or 23-0/7 to 24 wks' gestation.
- Controlled epidural is the anesthesia of choice for labor or C-section.
- Avoid general anesthesia in uncontrolled hypertension to minimize risk of catastrophic cerebral events.
- Continue magnesium sulfate through delivery process and for 24 hr postpartum or for at least 24 hr after the last convulsion.

DISPOSITION

- The maternal mortality rate for eclampsia averages 5% to 6%. Morbidity rate is 25%, including placental abruption (10%), disseminated intravascular coagulation, maternal apnea with fetal asphyxia, aspiration pneumonia, pulmonary edema (4%), renal failure, cardiopulmonary arrest, and coma.
- There is an increased risk of fetal death, neonatal death, preterm birth, and small-for-gestational-age birth.
- In patients with eclampsia, the risk of recurrence of eclampsia in a subsequent pregnancy is

about 2% and the risk of preeclampsia is about 25%. The use of daily low-dose aspirin starting at 12 to 16 (28) wk may decrease that risk.

REFERRAL

Because of the potential for serious permanent maternal and fetal sequelae, all cases should be managed by a team approach of obstetrician, maternal and fetal medicine, neonatologist, and intensivist.

BASIC INFORMATION

DEFINITION

An ectopic pregnancy (EP) occurs when a fertilized ovum implants outside the endometrial cavity.

SYNONYMS

Tubal pregnancy (97%) Interstitial (cornual) pregnancy (1% to 2%)
Ovarian pregnancy (1% to 3%)
Abdominal pregnancy (0.03% to 1%)
Cervical pregnancy (0.5%)
Cesarean scar pregnancy (6% of women with prior cesarean)

ICD-10CM CODES	
O00.0	Abdominal pregnancy
O00.1	Tubal ectopic pregnancy
O00.2	Ovarian ectopic pregnancy
O00.8	Other ectopic pregnancy
O00.9	Ectopic pregnancy, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- 1.5% to 2% of pregnancies
- 2.7% of maternal deaths

PREVALENCE (IN U.S.): Accounts for up to 18% of women presenting to the emergency room with vaginal bleeding or abdominal pain. Currently over 100,000 reported cases/yr.

RISK FACTORS: Previous EP, previous pelvic infection (pelvic inflammatory disease, tuboovarian abscess, salpingitis), previous tubal ligation, previous tuboplasty, previous cesarean section, intrauterine device use, assisted reproductive techniques, infertility, cigarette use, age >35 yr, multiple lifetime sexual partners, DES exposure in utero

PHYSICAL FINDINGS & CLINICAL PRESENTATION:

- Abdominal tenderness: 95%
- Adnexal tenderness: 87% to 99%
- Peritoneal signs: 71% to 76%
- Amenorrhea or abnormal vaginal bleeding: 75%
- Adnexal mass: 33% to 53%
- Enlarged uterus: 6% to 30%
- Shock: 2% to 17%
- Shoulder pain: 10%
- Tissue passage: 6% to 7%

ETIOLOGY

- Anatomic obstruction to zygote passage
- Abnormalities in tubal motility
- Transperitoneal migration of the zygote

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Corpus luteum cyst
- Rupture or torsion of ovarian cyst
- Threatened or incomplete abortion
- Pelvic inflammatory disease
- Appendicitis
- Gastroenteritis
- Dysfunctional uterine bleeding
- Degenerating uterine fibroids
- Endometriosis

WORKUP

- The classic presentation of EP includes the triad of abnormal vaginal bleeding, pelvic pain, and an adnexal mass. Fig. 1 describes a diagnostic approach to suspected EP. Fig. 2 *(top)* describes potential sites of ectopic implantations. Consider in all women with abdominopelvic pain and a positive pregnancy test.
- Transvaginal ultrasound (Fig. 2 [bottom]).
- Quantitative serum human chorionic gonadotropin level.
- Type and screen if presents with vaginal bleeding; give Rhogam if Rh-negative status on initial presentation of vaginal bleeding with positive pregnancy test.
- Laparoscopy in equivocal situations and possibly for treatment.

LABORATORY TESTS

- Quantitative human chorionic gonadotropin (qhCG): Check on initial presentation. qhCG allows one to interpret initial ultrasound. If qhCG >6000 mIU/ml, should see intrauterine pregnancy (IUP) on abdominal scan; qhCG >1500 mIU/ml for transvaginal scan. The ability to visualize an early pregnancy is dependent on the gestational age and expertise of the ultrasonographer; therefore, some may use up to qhCG >3500 mIU/ml as the discriminatory threshold for transvaginal ultrasonography.
- Approximately 25% to 50% of women with an EP present with a pregnancy of unknown location, meaning that the initial ultrasound does not show a pregnancy in the uterus or the fallopian tube. Therefore, serial measurement of qhCG, typically obtained every 2 days, can help distinguish between an IUP, resolving miscarriage, or EP.
- The expected rate of qhCG increase varies by the initial starting hCG. For an initial hCG level <1500 mIU/ml, the expected rate of increase is 49%, compared to 40% for an initial hCG level between 1500 and 3000 mIU/ml, and a 33% increase for an initial hCG >3000 mIU/ml.
- Dropping hematocrit may be associated with tubal rupture or possible abnormal intrauterine pregnancy.

IMAGING STUDIES

- Ultrasound: Presence of an intrauterine yolk sac makes EP extremely unlikely. However, if the patient used assisted reproductive technologies, a heterotopic pregnancy (an EP with concurrent IUP) is a possibility. A repeat ultrasonographic examination within 7 days after presentation may identify the location of a pregnancy that was not identified on initial ultrasonographic examination.
- Findings on ultrasound in EP include:
  1. Empty uterus (i.e., no yolk sac or fetal pole; a pseudosac in uterus may appear similar to a gestational sac)
  2. Adnexal mass (typically separate from adjacent ovary, commonly seen with "ring of fire" appearance)
  3. Enlarged hysterotomy scar, may bulge beyond contour of the uterus
  4. Fluid in cul-de-sac
  5. Yolk sac and/or fetal pole in tube
  6. Fetal cardiac activity in adnexa

TREATMENT

NONPHARMACOLOGIC THERAPY

Surgery performed via laparoscopy is preferred; however, laparotomy is appropriate if patient is very unstable or if visualization of the pelvis is poor at the time of laparoscopy.

- Salpingostomy, or resecting EP with conservation of tube, has the potential benefit of higher rates of subsequent IUP; however, recent randomized controlled trials suggest there is no difference in fecundity rate between salpingostomy and salpingectomy. The procedure requires postoperative serial monitoring of qhCG.
- Salpingectomy, or removal of affected fallopian tube, is considered the standard surgical procedure and is preferred in the following circumstances:
  1. Ruptured tube
  2. Future fertility not desired
  3. Recurrent EP in the same tube
  4. Uncontrolled hemorrhage
- Direct injection of chemotherapy into the EP by laparoscopy, transvaginal ultrasound, or hysteroscopy. Direct injection of methotrexate, and possibly KCl if there is active cardiac activity, may be performed when the pregnancy is in a location where there is high morbidity, such as the cervix, cesarean section scar, or cornu.
- Cervical and cesarean scar pregnancies may be managed with a combination of methotrexate administration, laparoscopic and/or hysteroscopic techniques, uterine artery embolization, laparotomy, and possible hysterectomy.

ACUTE GENERAL Rx

- Medical management with methotrexate, a folic acid antagonist, is a safe alternative if the patient is stable. Check the methotrexate safety labs prior to administration (CBC, creatinine, LFTs).
- Contraindications:
  1. Hemodynamically unstable; ruptured EP
  2. Patient unable to comply with follow-up
  3. Medical contraindication to methotrexate including the following: Hepatic or renal disease, thrombocytopenia, leukopenia, or significant anemia
  4. Breastfeeding, preexisting blood dyscrasias, known sensitivity to methotrexate, active pulmonary disease, chronic liver disease, alcoholism, laboratory evidence of immunodeficiency, renal disease, and peptic ulcer disease
  5. Intrauterine gestation

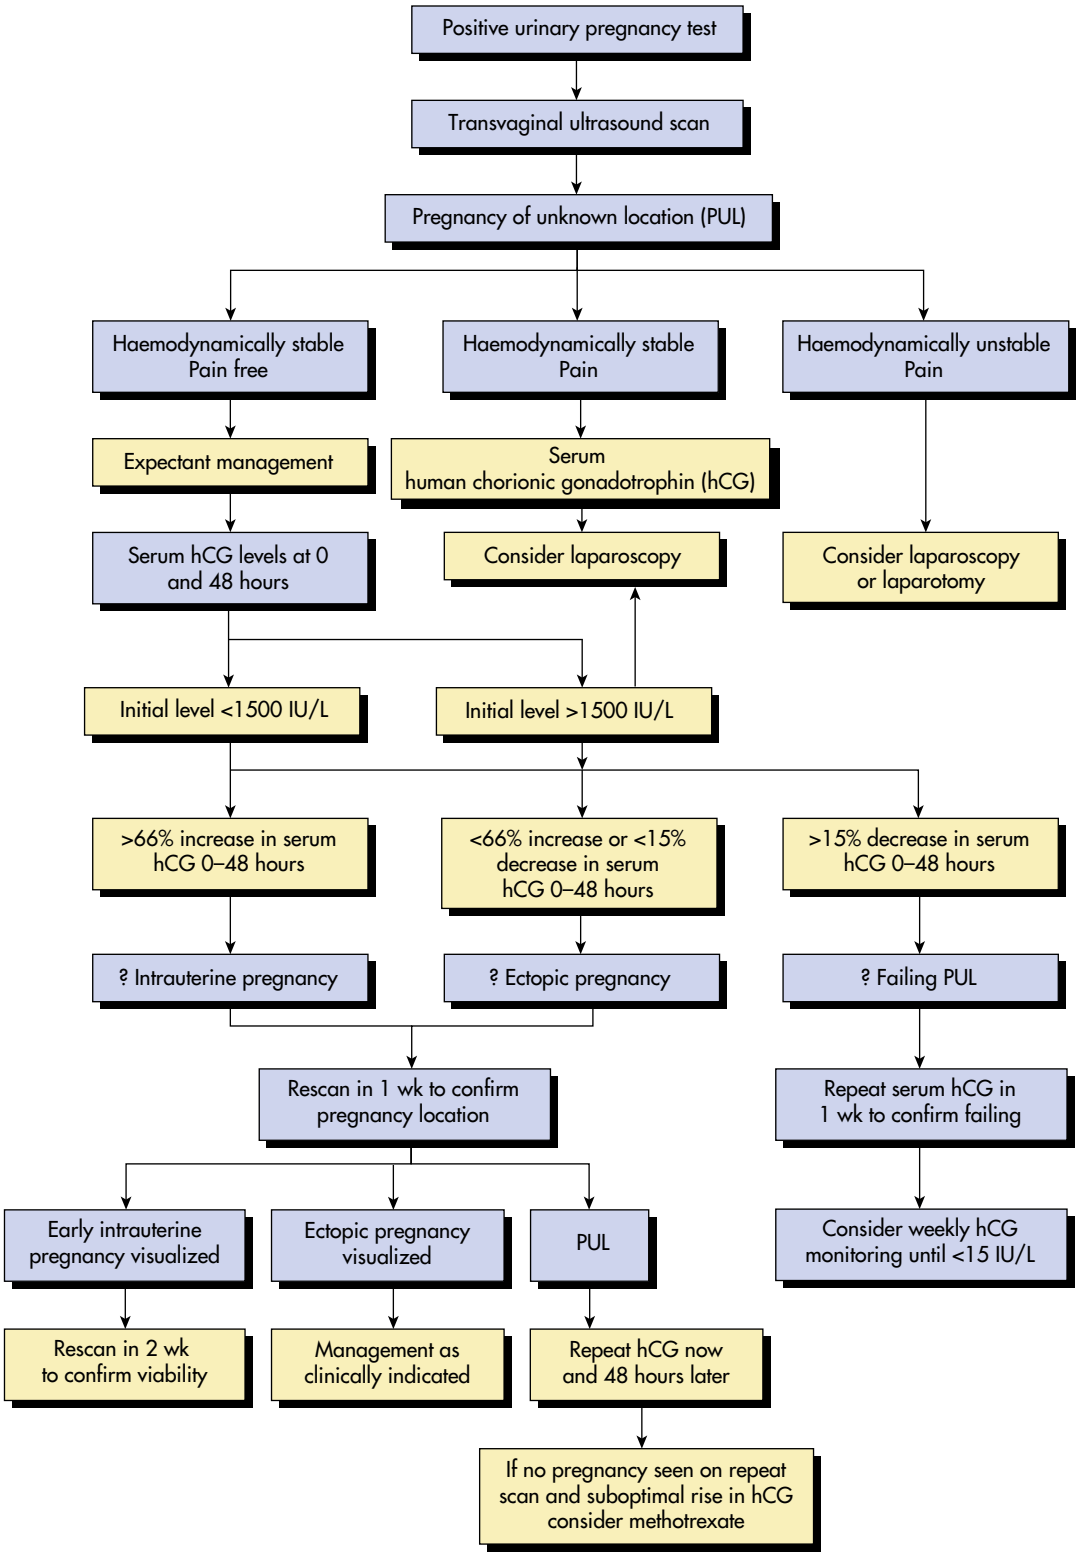

FIG. 1 Algorithm for managing suspected ectopic pregnancy. *hCG,* Human chorionic gonadotrophin; *PUL,* pregnancy of unknown location. (From Magowan BA: *Clinical obstetrics & gynecology,* ed 4, 2019, Elsevier.)

- Relative contraindications:
  1. EP >3.5 cm mass
  2. qhCG >5000 mIU/ml (more likely to require multidose regimen)
  3. Presence of cardiac activity in the fetus
- Most common regimen is methotrexate 50 mg/m^2 of body surface area and is administered on day 1. May require second dose or surgical intervention if qhCG increases or plateaus (<15% drop) when comparing values from day 4 and 7.
- Success rate of single-dose protocol approximately 88.1%. Rupture during methotrexate treatment ranges from 7% to 14%.
- Other methotrexate regimens include multidose protocol ± leucovorin rescue.
- Methotrexate side effects include nausea, vomiting, stomatitis, diarrhea, elevated LFTs, abdominal pain, and nephrotoxicity.

CHRONIC Rx

Persistent EP results from residual trophoblastic tissue or secondary implantation after conservative surgery. There is a 5% incidence of persistent EP with conservative treatment.

DISPOSITION

If diagnosed and treated early (before rupture), prognosis is excellent for good recovery. Monitor qhCG weekly until negative. Use reliable contraception until qhCG is negative. With subsequent pregnancies, follow qhCG and perform early ultrasound to confirm IUP. There is a 10% recurrence rate for EP.

REFERRAL

Should obtain gynecologic consultation if EP is suspected.

PEARLS & CONSIDERATIONS

Any patient who presents with vaginal bleeding, abdominal pain, or both with a positive pregnancy test and no prior documented IUP needs to be assessed for ectopic pregnancy.

Ehlers-Danlos Syndrome (PTG)

BASIC INFORMATION

DEFINITION

Ehlers-Danlos syndrome (EDS) is a clinically and genetically heterogeneous group of connective tissue disorders (HCTDs) characterized by joint hypermobility, skin hyperextensibility, and tissue fragility.

SYNONYM

EDS

ICD-10CM CODE
Q79.6 Ehlers-Danlos syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- The prevalence of EDS is estimated to be approximately 1 in 5000 births, although it is somewhat higher in African Americans.
- The 2017 International Classification of Ehlers-Danlos Syndromes recognizes 13 subtypes (Table E1).
- In view of the vast genetic heterogeneity and phenotypic variability of the EDS subtypes and clinical overlap between many of the subtypes, but with other HCTDs, the definite diagnosis relies for all subtypes, except hEDS, on molecular confirmation with identification of causative variants(s) in the respective gene.
- For most of the subtypes, mutations have been identified in collagen-encoding genes, or in genes encoding collagen-modifying enzymes.
- Classical EDS (cEDS) and hypermobile EDS (hEDS) are most prevalent. cEDS accounts for approximately 80% of reported cases.
- Diagnosis of hEDS remains a clinical one.
- Vascular EDS (vEDS) is the most dangerous because it is associated with spontaneous rupture of medium and large arteries and hollow organs, especially the large intestine and uterus.
  1. Vascular events occur in 4% of patients with vEDS.
  2. They typically occur between the third and fifth decades of life.
  3. Most vascular complications consist of arterial dissections.
- Inheritance pattern is either autosomal dominant (AD) or autosomal recessive (AR).
- The 2017 classification of Ehlers-Danlos syndrome is summarized in Table E1.
- Diagnostic criteria for the various subtypes of EDS may require fulfilling components of either major and/or minor criterion with minimal criteria suggestive for each EDS subtypes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- cEDS: Patients have moderate to severe skin hyperelasticity (Fig. E1); easy scarring and bruising ("cigarette-paper scars"); smooth, velvety "doughy" skin, "piezogenic papules" (fat herniations through the fascia on sides of feet), molluscoid pseudotumors (bluish-gray to violaceous, spongy 1 to 2 cm nodules over easily traumatized bony areas such as the shin, forearms, and Achilles tendon, which represents herniation of subcutaneous fat through atrophic dermal scars), and subcutaneous spheroids (small, firm, hard calcified, subcutaneous nodules due to fat necrosis); hyperextensibility ("Gorlin sign": Ability to touch tip of tongue to nose [Fig. E2]); and joint hypermobility (Fig. E3) and dislocation (Fig. E4). Patients have complications such as hernias, pelvic organ prolapse, premature osteoarthritis, and cervical insufficiency.
- hEDS: Most frequent form, large- and small-joint and spine hypermobility, causes recurrent joint dislocations, often leaving a patient unable to walk.
  1. Chronic limb or joint pain is a prominent feature and may resemble fibromyalgia.
  2. Patients develop scoliosis and premature osteoarthritis.
  3. Skin involvement is less prominent
     a. Skin is sometimes soft and smooth with mild hyperextensibility. Piezogenic papules may be seen. Keratosis pilaris/hyperkeratosis of the extensor surfaces and striae can occur.
  4. Other features include delayed gastric emptying and irritable bowel syndrome.
  5. Autonomic dysfunction, including postural orthostatic tachycardia syndrome (POTS), can occur.
  6. Sleep apnea and headaches are reported in one-third of patients (migraines; tension-type headaches, including "brain fog" and headaches form cerebrospinal fluid leakage; Chiari malformation; and cervicogenic), and poor proprioception, swelling, and varicosities of legs. Resistance to local anesthetic drugs and opioids has been reported.
  7. Mild aortic root dilatation and mitral valve prolapse can be seen.
- Vascular EDS (vEDS): vEDS is a potentially life-threatening condition with increased risk of spontaneous vascular or visceral rupture and the absence of large-joint hyperextensibility.
  1. Cardinal features include distinctive facial features (pinched nose, thin lips, tight skin, hollow cheeks, lobeless ears); acrogeria; thin translucent skin; excessive bruising; and, most important, rupture of vessels and viscera, including the arterial, intestinal, and uterine walls.
  2. Vessels most prone to rupture are the abdominal aorta and its branches, great vessels of aortic arch, and large arteries of limbs.
     a. Preexisting aneurysms are rarely detected before rupture, as they are typically pseudoaneurysms.
     b. Spontaneous rupture of internal organs occurs in the sigmoid colon, spleen, liver, and uterus.
  3. Facial features are often not prominent in children, and vascular EDS is usually not diagnosed until adulthood.
  4. Vascular rupture, GI perforation, or other organ rupture are presenting signs in 70% of adults with vascular EDS; presentation is often dramatic and unexpected. The average age for first major arterial or GI complication is 23 yr.
  5. Maternal mortality during pregnancy is about 12%; delivery is often uneventful.
- Kyphoscoliotic EDS (kEDS): Rare; characterized by marked muscular hypotonia, osteopenia, joint hypermobility, club foot deformity, progressive scoliosis, ocular fragility and possible globe rupture, mitral valve prolapse, and aortic dilation. Progressive kyphoscoliosis can result in respiratory complications requiring surgery. The skin is hyperextensible and typically velvety, pale, and translucent, with poor wound healing.
- Arthrochalasia EDS (aEDS): Prominent joint hypermobility with subluxations, congenital bilateral hip dislocation, extremity contractures, thoracolumbar scoliosis (short stature), skin hyperextensibility, and tissue fragility.
- Dermatosparaxis EDS (dEDS): Characterized by severe skin fragility with decreased elasticity, sagging redundant skin, and large hernias. Blue sclerae, typical facial feature, and severe bruising are present.
- Spondylodysplastic EDS (spEDS): Characterized by short stature; blue sclera; delayed tooth eruption and hypodontia; joint laxity with particular skeletal pattern (platyspondyly, osteopenia, widened metaphyses, flattened epiphyses, small ilia, short broad femoral neck, and short metacarpals and phalanges); velvety, hyperextensible, thin skin with prominent veins; and delayed wound healing with atrophic scars.
- Musculocontractural EDS (mcEDS): Characterized by craniofacial features (broad forehead, small mouth, and micrognathia in infancy, protruding jaw in adolescence, low set prominent rotated ears, blue sclerae, short nose, thin upper lip, and long philtrum), thumb and finger contractures, club feet, severe kyphoscoliosis, hypotonia, hyperextensible thin skin with easy bruising, atrophic scars, joint laxity, and organ fragility.

ETIOLOGY

- The underlying genetic and pathogenic mechanisms of EDS subtypes are outlined in Table E2.
- Defects of collagen-encoding genes, or in genes encoding collagen-modifying enzymes expressed in multiple tissues (skin, tendons, blood vessels, and viscera) underlie all forms of EDS.
- cEDS is associated with defects in type V collagen, corresponding to mutations of *COL5A1* and *COL5A2* genes, rarely defects in type I collagen, corresponding to mutations in *COL1A1*.
- Vascular EDS (vEDS) involves a deficiency in type III collagen, and several genetic studies suggest that heterozygous mutations in the *COL3A1* gene lead to this deficiency. There are rare exception(s) of specific heterozygous arginine-to-cysteine substitution in *COL1A1* that are also associated with vascular fragility mimicking *COL3A1-vEDS.*
- Arthrochalasia EDS (aEDS) results from a defect in type I collagen, caused by mutations in the *COL1A1* and *COL1A2* genes.
- Genetic testing for hEDS is not available. Diagnosis is made on clinical basis.

TABLE E1 Clinical Classification of the Ehlers-Danlos Syndromes Inheritance Patterns and Genetic Basis

Clinical EDS Subtypes	Abbreviation*	Inheritance Pattern	Genetic Basis	Protein	Diagnostic Criteria
Classical EDS	cEDS (classical EDS types I and II)	AD	Major: *COL5A1*, *COL5A2* Rare: *COL1A1*	Type V collagen Type I collagen	• Major criteria: Skin hyperextensibility and atrophic scarring Generalized joint hypermobility (GJH) • Minor criteria: Easy bruising Soft, doughy skin Skin fragility Molluscoid pseudotumors Subcutaneous spheroids Hernia Epicanthal folds Complications of joint hypermobility (e.g., sprains, luxation/subluxation, pain, flexible flatfoot) Family history of a first-degree relative who meets clinical criteria • Minimal criteria suggestive for cEDS: - Major criteria: Skin hyperextensibility and atrophic scarring Plus - Either major criterion: GJH - And/or: At least three minor criteria Confirmatory molecular testing
Classical-like EDS	clEDS (tenascin X deficiency)	AR	*TNXB*	Tenascin XB	• Major criteria: Skin hyperextensibility, with velvety skin texture and absence of atrophic scarring GJH (most common shoulder and ankle) Easily bruised skin/spontaneous ecchymoses • Minor criteria: Foot deformities: Broad/plump forefoot Brachydactyly, with excessive skin; pes planus; hallus valgus, piezogenic papules Edema of the legs in the absence of cardiac failure Mild proximal and distal muscle weakness Axonal polyneuropathy Atrophy of muscles in hands and feet Acrogenic hands, mallet finger(s) Clinodactyly, brachydactyly Vaginal/uterine/rectal prolapse • Minimal criteria suggestive for clEDS: All three major criteria AND a family history compatible with AR transmission Confirmatory molecular testing
Cardiac-valvular	cvEDS	AR	*COL1A2*	Type I collagen	• Major criteria: Severe progressive cardiac-valvular problems (aortic valve, mitral valve) Skin involvement: Skin hyperextensibility, atrophic scars, thin skin, easy bruising Joint hypermobility (generalized or restricted to small joints) • Minor criteria: Inguinal hernia Pectus excavatum Joint dislocation Foot deformities: Pes planus, pes planovalgus, hallus valgus • Minimal criteria for cvEDS: - Major criterion: Severe progressive cardiac-valvular - AND family history compatible with AR inheritance Plus - Either: One or more major criterion - And/or: At least two minor criteria Confirmatory molecular testing

Dx DIAGNOSIS

- The diagnosis of hEDS remains clinical as there is no reliable or appreciable genetic test. The syndromic presentation may vary with age and gender
- There is also a clinical spectrum ranging from asymptomatic joint hypermobility through nonsyndromic hypermobility with secondary manifestations to hEDS
- The clinical diagnosis of hEDS needs the simultaneous presence of three criteria, all of which must be present

  Criterion 1: Generalized joint hypermobility (small and large joints)

  Criterion 2: Two or more features of A, B, or C

  Feature A: Five or more of the following:
  1. Unusual velvety skin
  2. Mild skin hyperextensibility
  3. Unexplained striae (without weight gain or loss)
  4. Bilateral piezogenic heel papules
  5. Recurrent or multiple abdominal hernias(s) (e.g., umbilical, inguinal, crural)
  6. Atrophic scarring (not as severe as seen in cEDS or vEDS)
  7. Pelvic floor, rectal, and/or uterine prolapse in children, men, or nulliparous women without a history of morbid obesity or etiology
  8. Dental crowding and high or narrow palate
  9. Arachnodactyly, as defined as one or more of the following: (i) Positive wrist sign (Steinberg sign) on both sides; (ii) positive thumb sign (Walker sign) on both sides
  10. Arm span-to-height ≥1.05
  11. Mitral valve prolapse (MVP) mild or greater based on echocardiogram
  12. Aortic root dilatation with Z-score >+2 standard deviation above the mean

  Feature B: Positive family history in first-degree relatives diagnosed with these criteria

  Feature C: Musculoskeletal complications (must have at least one):
  1. Daily musculoskeletal pain in two or more extremities (at least 3 mo)
  2. Chronic, widespread pain for 3 mo or more
  3. Recurrent joint dislocations or atraumatic joint instability

  Criterion 3: No evidence of skin fragility or other connective tissue disorder
- Caveats
  1. Joint hypermobility is more common in females and young children, and as patient gets older, joint hypermobility decreases with development of early onset osteoarthritis followed by surgical intervention
  2. Diagnostic testing-genetic testing is not available
- Differential diagnosis for hEDS
  1. Neuromuscular disorders
  2. Other EDS subtypes
  3. Other HCTD
     a. Marfan syndrome
     b. Autosomal dominant cutis laxa
     c. Larsen syndrome
     d. Stickler syndrome
     e. Loeys-Dietz syndrome
     f. Osteogenesis imperfecta
     g. Arterial tortuosity syndrome

WORKUP

Diagnosis is based on clinical criteria and genetic testing.

LABORATORY TESTS

- Genetic testing for known molecular defects recommended to confirm the diagnosis, but genetic testing is not available for hEDS.
- Plain radiographs may reveal calcified nodules along the shin or forearms corresponding to the subcutaneous spheroids.
- Echocardiography can identify valvular abnormalities and aortic dilation.

Rx TREATMENT

- All patients should receive genetic counseling about the mode of inheritance of their EDS.
- Management of most skin and joint problems should be conservative and preventative.
  1. Physical therapy to strengthen muscles can be helpful.
  2. Acetaminophen for pain control. NSAIDs can be used but may exacerbate easy bruising.
  3. Joint hypermobility and pain in EDS usually does not require surgical intervention.
     a. Surgical repair and tightening of joint ligaments can be performed, but ligaments frequently will not hold sutures.
     b. Surgical intervention should be considered on an individual basis.
- Annual ophthalmologic examinations should be performed in all patients with EDS to detect early retinal or scleral fragility, myopia, and glaucoma.
- For patients with vascular EDS:
  1. Special surgical care is required because of increased tissue friability.
  2. Patients should be advised to avoid contact sports.
  3. Elevated blood pressure should be aggressively treated with beta-blockers, given the risk of arterial dissection.
  4. A β_1-selective agent with partial β_2-agonist activity, celiprolol, has been shown to decrease the incidence of arterial rupture or dissection in a small study.
  5. In the case of bleeding, desmopressin should be considered as it stimulates release of endothelial von Willebrand factor and of aminocaproic acid to counteract fibrinolysis.

DISPOSITION

Prognosis varies according to the subtypes of EDS. For vEDS:

- 25% will have a complication by age 25 yr; >80% will have a complication by age 40 yr.
- Most vascular complications consist of arterial dissections.
- Vascular events typically occur between the third and fifth decades of life.
- Median age of survival is 48 yr. Most deaths are related to arterial rupture.

REFERRAL

- Geneticist for genetic testing, if applicable, and genetic counseling
- Cardiology for ongoing monitoring and treatment of valvular abnormalities and aortic dilation
- Ophthalmology for annual examination to detect retinal or scleral fragility, myopia, and glaucoma
- Physical therapy for strengthening of core and extremity muscles and joint stability
- Orthopedic surgeon, general surgeon, or obstetrician/gynecologist as needed

FIG. E2 Ehlers-Danlos syndrome (EDS). Gorlin sign is five times more common in EDS patients than in normal individuals. Note the scars on the forehead. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Joint hyperextensibility in classical Ehlers-Danlos syndrome. (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.)

FIG. E4 Ehlers-Danlos syndrome. Hyperextensible joints may result in double-jointed fingers, as seen in this girl. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

PEARLS & CONSIDERATIONS

- Women with vascular EDS should be counseled about the risk of uterine, intestinal, and arterial rupture.
- Pregnancy is associated with up to a 25% mortality rate; however, successful childbirth is possible.
- There is a 50% chance that the child will be affected.
- Family members of patients with different EDS subtypes should be recommended for evaluation for EDS and genetic testing and counseling.

Ehrlichiosis and Anaplasmosis PTG

BASIC INFORMATION

DEFINITION

Human monocytic ehrlichiosis (HME) and human granulocytic anaplasmosis (HGA) are tick-borne rickettsial diseases. Ehrlichiosis is the generic name for infections caused by both *Ehrlichia* and *Anaplasma* genera. Table 1 describes the agent, vector, and geographic prevalence of these diseases.

SYNONYMS

Human granulocytic ehrlichiosis (HGE)
Ehrlichiosis
Human monocytic ehrlichiosis (HME)
Human monocytotropic ehrlichiosis
Human granulocytic anaplasmosis (HGA)
Human granulocytotropic ehrlichiosis
Anaplasmosis
Human granulocytropic anaplasmosis
HGE
HGA
HME

ICD-10CM CODES

A77.40 Ehrlichiosis, unspecified
A77.41 Ehrlichiosis chaffeensis [*E. chaffeensis*]
A77.49 Other ehrlichiosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Highest overall incidence in Rhode Island (36.5 per 1 million), New York, New Jersey, Connecticut, Wisconsin, Minnesota, and northern California; >3000 cases identified in the United States since 2006.
PREDOMINANT SEX: Males outnumber females by 2 to 1.
PREDOMINANT AGE: Most severe disease 50 to 70 yr
PEAK INCIDENCE: Occurs throughout the yr, with peak incidence between May and July and again in September

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms of ehrlichiosis typically appear after a median of 9 days (range 5 to 14 days)
- Most common initial symptoms
  1. Fever (96%)
  2. Chills, rigor
  3. Headache (72%)
  4. Myalgia
- Subsequent symptoms
  1. Anorexia, nausea
  2. Arthralgia
  3. Cough
  4. Confusion (meningoencephalitis in 20% of patients with HME)
  5. Abdominal pain
  6. Rash (erythematous to pustular) <30% in HME, uncommon in HGA
- Complications
  1. Hepatitis
  2. Interstitial pneumonitis; acute respiratory distress syndrome
  3. Renal and respiratory failure
  4. Demyelinating polyneuropathy
  5. Toxic shock–like syndrome
  6. Life-threatening opportunistic infections, usually HGA

ETIOLOGY

- The causative agents are *Ehrlichia chaffeensis* for human monocytic ehrlichiosis (HME) and *Anaplasma phagocytophilum* for human granulocytic anaplasmosis (HGA) and *Ehrlichia ewingii* for human granulocytic ehrlichiosis (HGE)
- Vector
  1. Almost certainly tick-borne, recently confirmed to be rarely transmitted by infected blood (including nosocomial infection). Perinatal and transplant transmission have been documented.
  2. Transmitted by *Ixodes scapularis* in the northeastern states and *Amblyomma americanum* in the south central, southeastern, and mid-Atlantic states. Fig. 1 illustrates the life cycles of human monocytic ehrlichiosis (HME, with *Ehrlichia chaffeensis*) and human granulocytic ehrlichiosis (anaplasmosis).
  3. Tick exposure reported in >90% of patients, with ~60% reporting tick bite.
- Mammalian host: Deer, horses, dogs, white-footed mice, cattle, sheep, goats, bison
- Host inflammatory and immune responses define final spectrum of disease beyond granulocytes, including hepatitis, interstitial pneumonitis, and nephritis with mild azotemia
- Between 6% and 21% of patients with HGA also have serologic evidence of other *Ixodes* spp. tick-borne diseases: Lyme disease or babesiosis
- Recovery is usual outcome; fatality rate of HGE is about 1%
- ICU care required: 7%

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rocky Mountain spotted fever, Colorado tick fever, Q fever, relapsing fever
- Babesiosis
- Leptospirosis
- Lyme disease
- Tularemia
- Typhoid fever, paratyphoid fever
- Brucellosis
- Viral hepatitis
- Meningococcemia
- Infectious mononucleosis
- Hematologic malignancy
- TTP (thrombotic thrombocytopenic purpura)
- Table 2 describes clinical clues suggesting a diagnosis of a tick-borne illness manifesting as a nonspecific febrile illness

WORKUP

- Acute blood samples for Giemsa-stained smears
- CBC (leukopenia, thrombocytopenia), liver function (elevated), blood urea nitrogen (BUN)/creatinine
- Acute serum samples for serology: Antibodies are seldom detected at time of acute infection (they usually appear 2 to 4 wk following clinical illness)
- Chest radiograph examination
- Bone marrow rarely needed

LABORATORY TESTS

- Polymerase chain reaction (PCR) to facilitate early diagnosis: Detection of *Ehrlichia/Anaplasma* DNA in blood or cerebrospinal fluid (CSF) by PCR (Table E3)
- Giemsa-stained smear demonstrating morulae of the organism within granulocytes or monocytes (sensitivity 20% to 75%) (Fig. E2)
- CBC: Progressive leukopenia and thrombocytopenia with nadir near day 7
- C-reactive protein concentration is generally elevated
- Liver function tests (LFTs): Increase in hepatic transaminases, lactate dehydrogenase, and alkaline phosphatase
- Elevated plasma creatinine concentration may be seen
- Serologic titer (IFA) >80 or fourfold increase in titer to antigen

IMAGING STUDIES

- Chest radiograph examination to show interstitial pneumonitis (unusual)
- MRI of the brain in cases of encephalitis

TREATMENT

ACUTE GENERAL Rx

- Immediate therapy to limit extent of acute illness and complication
- Doxycycline: 100 mg twice a day for 7 to 14 days is therapy of choice for adults and children >8 yr (4 mg/kg/day in 2 divided doses)
- Doxycycline is now recommended as well for children aged <8 yr (Redbook 2018)
- Rifampin: 300 mg twice a day for 7 to 10 days can be used in pregnancy and for children <8 yr at 10 mg/kg twice per day
- Most patients defervesce within 24 to 48 hr given appropriate treatment.

PROGNOSIS

Poor prognostic indicators include:
- Advanced age or immunosuppression
- Concomitant chronic illness (such as diabetes mellitus, collagen-vascular disease)
- Lack of diagnosis recognition
- Delayed onset of specific antibiotic therapy
- Concomitant HIV or organ transplant status

DISPOSITION

Repeat CBC every 2 to 4 wk until normal.

REFERRAL

For consultation with infectious diseases specialist in suspected cases

PEARLS & CONSIDERATIONS

- A new pathogenic *Ehrlichia* species, closely related to *E. muris,* has been identified in Minnesota and Wisconsin. Organism-specific PCR and serologic testing can be used for identification.
- Duration of time tick must be attached to produce illness as few as 4 hr.

- Delay in antibiotic treatment results in poorer outcome. Antibiotic treatment should be initiated as soon as infection is suspected.

Anaplasmosis (Patient Information)

AUTHOR: **Patricia Cristofaro, MD**

TABLE 1 Human Ehrlichioses and Anaplasmosis

	Human Monocytotropic Ehrlichiosis	Human Granulocytotropic Ehrlichiosis	Human Granulocytotropic Anaplasmosis
Former disease nomenclature	Human monocytic ehrlichiosis	Human granulocytic ehrlichiosis	Human granulocytic ehrlichiosis
Causative agent(s)	*Ehrlichia chaffeensis*	*Ehrlichia ewingii, Ehrlichia cani*—one asymptomatic human case reported in Venezuela	*Anaplasma phagocytophilum*
Leukocyte targets	Monocytic cell phagosomes	Neutrophil phagosomes	Granulocyte-neutrophil phagosomes
Tick vectors	*Amblyomma americanum* (lone star ticks)	*Amblyomma americanum* (lone star ticks), *Dermacentor variabilis* (American dog ticks)	*Ixodes persulcatus* complex (American deer ticks)—*I. scapularis, I. ricinus, I. pacificus*
Animal reservoirs	White-tailed deer, coyotes, dogs	White-tailed deer, dogs	Rodents, deer, ruminants, horses
U.S. regional distribution	Southeastern and south central United States	South central United States	Northeastern United States, upper Midwest, northern California
U.S. regional prevalence	2-5 cases/100,000	≤10% of presumed HME cases have *E. ewingii* infections in south central United States	50-60 cases/100,000; high seroprevalence rates in children (>20%) who have had subclinical infections
Seasonal occurrences	April-September, peaking in July	Spring-fall	May-July
Incubation periods (wk)	1-4	1-4	1-4
Modes of transmission	Tick bite, blood product transfusion	Tick bite, blood product transfusion	Tick bite, blood product transfusion, nosocomial
Frequently presenting clinical manifestations	Fever, malaise, headache, myalgias, rash in <40%	Same initial manifestations, but much milder, except in immunocompromised individuals	Fever, malaise, headache, myalgias; rarely rash
Laboratory abnormalities	Leukopenia, thrombocytopenia, transaminitis	Leukopenia, thrombocytopenia, transaminitis	More pronounced and prolonged leukopenia, thrombocytopenia, transaminitis
Potential complications, especially in immunocompromised individuals	Meningoencephalitis, acute renal and respiratory failure, hepatitis, myocarditis	Milder and less likely, except in patients immunocompromised by HIV/AIDS, organ transplantation, prolonged corticosteroid therapy	May be significant in immunocompromised patients with high fevers, seizures, confusion, hemorrhagic diathesis, rhabdomyolysis, shock, acute tubular necrosis, adult respiratory distress syndrome; some specific CNS complications may include eighth nerve palsy, brachial plexopathy, demyelinating polyneuropathy
Case-fatality rate (CFR)	3%, higher in immunocompromised individuals	No deaths reported	0.5%, higher CFR in immunocompromised individuals
Recommended confirmatory diagnostic tests	Wright-stained peripheral blood smears with characteristic intracytoplasmic morulae in monocytes, DNA detection by PCR assay, culture	Wright-stained peripheral blood smears with characteristic intracytoplasmic morulae in neutrophils, DNA detection by PCR	Wright-stained peripheral blood smears with characteristic intracytoplasmic aggregates in neutrophils, DNA detection by PCR assay, increased immunofluorescent antibodies in initial and paired serum samples
Current antibiotic resistance	Fluoroquinolones	Fluoroquinolones	Fluoroquinolones
Currently recommended antibiotic therapy, adults	Doxycycline, 100 mg PO bid, or tetracycline, 250-500 mg PO qid, for minimum of 3 days after defervescence to maximum of 14-21 days	Doxycycline, 100 mg PO bid, or tetracycline, 250-500 mg PO qid, for minimum of 3 days after defervescence to maximum of 14-21 days	Doxycycline, 100 mg PO bid, or tetracycline, 250-500 mg PO qid for minimum of 3 days after defervescence to maximum of 14-21 days
Currently recommended antibiotic therapy, children	Doxycycline, 4.4 mg/kg PO bid, or tetracycline, 25-50 mg/kg PO qid, for minimum of 3 days after defervescence to maximum of 14-21 days	Doxycycline, 4.4 mg/kg PO bid, or tetracycline, 25-50 mg/kg PO qid, for minimum of 3 days after defervescence to maximum of 14-21 days	Doxycycline, 4.4 mg/kg PO bid, or tetracycline, 25-50 mg/kg PO qid, for minimum of 3 days after defervescence to maximum of 14-21 days

bid, Twice daily; *CNS,* central nervous system; *DNA,* deoxyribonucleic acid; *HME,* human monocytotropic ehrlichiosis; *HIV/AIDS,* human immunodeficiency virus infection/acquired immunodeficiency syndrome; *PCR,* polymerase chain reaction; *PO,* by mouth; *qid,* four times a day.

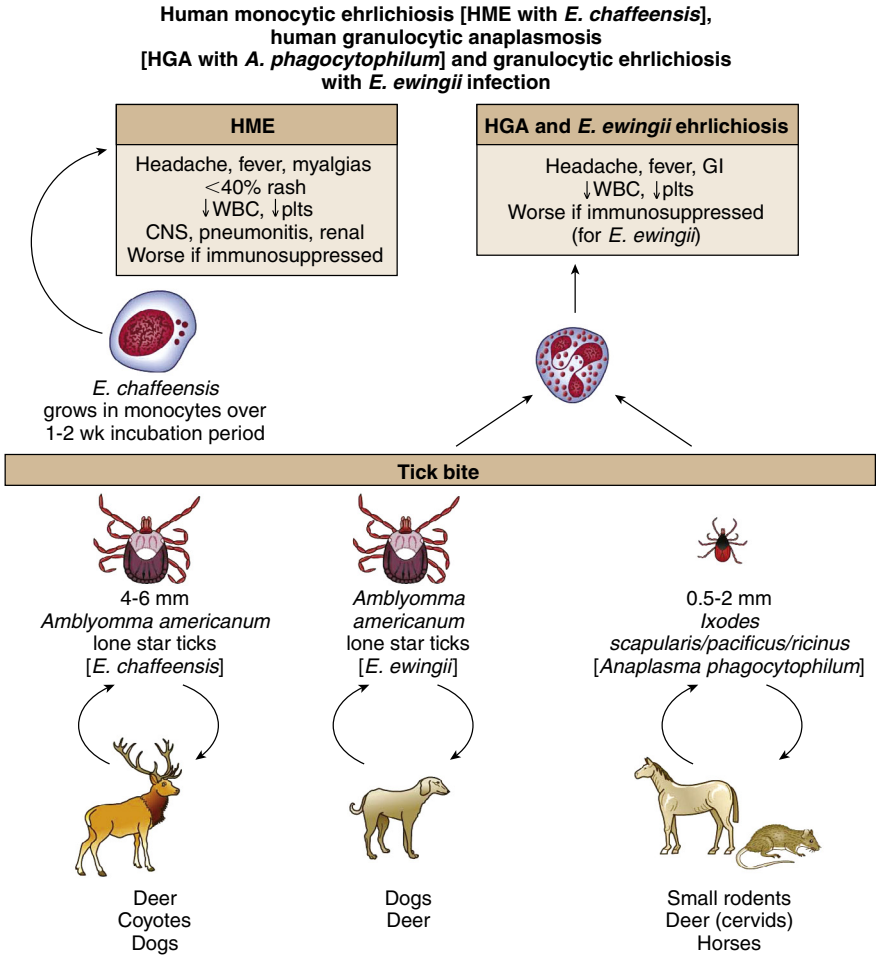

FIG. 1 Life cycles of human monocytic ehrlichiosis (*HME*, with *Ehrlichia chaffeensis*) and human granulocytic ehrlichiosis (anaplasmosis, *HGA* with *Anaplasma phagocytophilum*) or infection with *E. ewingii*. *CNS*, Central nervous system; *GI*, gastrointestinal; *WBC*, white blood cell count. (From Dumler JS: Ehrlichiosis and anaplasmosis. In Guerrant RL, Walker DH, Weller PF (eds): *Tropical infectious diseases: principles, pathogens and practice*, 3rd ed, Philadelphia, 2011, Elsevier, pp. 339-343.)

TABLE 2 Clinical Clues (History, Physical Examination, or Laboratory) Suggesting the Diagnosis of a Tick-Borne Illness Manifesting as a Nonspecific Febrile Illness*

Disease	Clues
Anaplasmosis	Faint rash possible Low white blood cell or platelet count Elevated hepatic transaminases
Babesiosis	Findings of hemolysis History of splenectomy Presence of faint rash, hepatomegaly, or splenomegaly
Lyme disease	Careful skin examination for any rash consistent with erythema migrans Bradycardia from heart block Associated seventh nerve palsy or lymphocytic meningitis
Colorado tick fever	Saddle-back fever curve
Rocky Mountain spotted fever	Maculopapular or petechial rash Normal white blood cell count or low platelet count Hyponatremia Peripheral edema
Relapsing fever	Recurring episodes of fever with afebrile intervals
Tularemia	Acrally located ulcer Regional lymphadenopathy Possible associated pneumonia

BASIC INFORMATION

DEFINITION

Disorders of ejaculation and orgasm include premature ejaculation, delayed ejaculation, anejaculation, retrograde ejaculation, painful ejaculation, hematospermia, and anorgasmia. Premature ejaculation refers to ejaculation that occurs sooner than desired, while delayed ejaculation refers to ejaculation that occurs after prolonged sexual stimulation. Anejaculation is the absence of semen propulsion from the urethra, with or without orgasm. Retrograde ejaculation is the backward flow of semen into the bladder. Hematospermia is the appearance of blood in the ejaculate. Anorgasmia is the inability to achieve orgasm despite sexual stimulation.

SYNONYMS

Ejaculatory dysfunction
Anejaculation
Anorgasmia
Aspermia
Dry orgasm
Dry ejaculate
Failure of emission

ICD-10CM CODES

R36.1	Hematospermia; Bloody ejaculation
F52.4	Premature ejaculation
F52.32	Male orgasmic disorder; Inhibited male orgasm; Anorgasmia
N53.11	Delayed ejaculation; Retarded ejaculation
N53.12	Painful ejaculation
N53.13	Anejaculatory orgasm; Anejaculation
N53.14	Retrograde ejaculation
N53.19	Other ejaculatory dysfunction

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Not well understood, due to variability in definitions and reporting.

PEAK INCIDENCE: Not well understood. Ejaculatory and orgasmic disorders may be primary (lifelong) if the condition has always been present, or secondary (acquired) if the condition developed after a period of normal function.

PREVALENCE: Premature ejaculation is the most prevalent male sexual complaint, affecting up to 30% of men. Delayed ejaculation is the least commonly reported, least studied, and least understood of the male sexual dysfunctions, with a prevalence rate of 1% to 5% according to some studies.

PREDOMINANT SEX AND AGE: These disorders have been reported among men aged 18 to 70 yr.

GENETICS: No known genetic predisposition.

RISK FACTORS: Men with ejaculatory dysfunction of any type usually indicate higher levels of relationship stress, sexual dissatisfaction, anxiety about sexual performance, and general health issues, compared to sexually functional men.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Premature ejaculation: Ejaculation occurs sooner than desired, often within 1 minute of penetration. Physical examination is normal. Up to 30% of patients may report concomitant erectile dysfunction.
- Delayed ejaculation: Ejaculation requires prolonged sexual stimulation, often 25 minutes or longer. Physical examination is normal.
- Anejaculation: No ejaculate (neither antegrade nor retrograde) is produced during orgasm, or the patient may not be able to achieve orgasm. Physical findings may reveal nervous system dysfunction (e.g., spinal cord injury); may present with infertility.
- Retrograde ejaculation: Little or no ejaculate is expelled out of the urethra at orgasm. Patients may report cloudy postcoital urine. Physical examination is usually normal; may present with infertility.
- Painful ejaculation: Urethral, perineal, scrotal, or testicular pain during or shortly after ejaculation. Physical examination is often normal but may demonstrate tenderness with palpation of external genitalia, or with digital rectal examination.
- Hematospermia: Reddish-brown ejaculate, usually painless. Physical findings are usually unremarkable; not associated with malignancy.
- Anorgasmia: The inability to achieve orgasm, despite adequate stimulation. Patients will not experience perineal contractions nor the pleasurable sensation associated with normal orgasm. Physical findings are usually unremarkable.

ETIOLOGY

- Premature and delayed ejaculation represent opposite ends of the spectrum of ejaculatory disorders. The underlying etiology is complex and multifactorial, and includes organic and psychogenic contributions. Box E1 summarizes the recommended and optional questions to establish the diagnosis of delayed ejaculation and to direct treatment.
- Anejaculation may result from pelvic surgery, trauma, or radiation; from neurologic sequalae of Parkinson disease, multiple sclerosis, spinal cord injury, or diabetes mellitus; from bilateral ejaculatory duct obstruction; or from psychological stress and anxiety.
- Retrograde ejaculation is most commonly caused by the use of medications (e.g., alpha-blockers) or surgical procedures (e.g., transurethral resection of prostate) that relax or disrupt the bladder neck. It can also result from retroperitoneal surgery, diabetes mellitus, and the previously mentioned neurologic diseases. Box 2 summarizes the causes of retrograde ejaculation, delayed ejaculation, anejaculation, and anorgasmia.
- Causes of painful ejaculation may be infectious (e.g., epididymo-orchitis, urethritis, prostatitis), obstructive (e.g., vasectomy, prostatectomy, hernia repair), nervous/musculoskeletal, or psychological. Temporary painful ejaculation is common after radical prostatectomy but usually resolves over time.
- Hematospermia is usually idiopathic, but may be secondary to prolonged abstinence, or due to infection or inflammation of the genitourinary tract.
- Anorgasmia may be caused by spinal cord injury, hormonal dysfunction, psychological factors, dysfunctional sexual techniques, or medications, particularly serotonin reuptake inhibitors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Erectile dysfunction
- Hypogonadism
- Ejaculatory duct obstruction
- Urethral stricture disease
- Urethritis or sexually transmitted infection

LABORATORY TESTS

- For a low-volume ejaculate, post-ejaculate urine may be evaluated for the presence of spermatozoa to differentiate between failure of emission and retrograde ejaculation.
- Hematuria, in the setting of hematospermia or painful ejaculation, may signal an underlying inflammatory disorder or a malignancy and should prompt a complete evaluation.
- A fasting blood glucose or hemoglobin A1c test may be considered if diabetes is suspected as a cause of lack of emission or retrograde ejaculation.
- Urinalysis, urine culture, and screening for sexually transmitted diseases, when indicated, can rule out an infectious etiology of painful ejaculation.

IMAGING STUDIES

Transrectal ultrasonography or pelvic MRI can detect an ejaculatory duct obstruction or absence of the seminal vesicles. While not routinely used in the evaluation of ejaculatory and orgasmic disorders, they may be useful with persistently painful ejaculation

TREATMENT

NONPHARMACOLOGIC THERAPY

- Premature ejaculation can improve with psychotherapy and behavioral interventions (e.g., "coronal squeeze" or "start-and-stop" technique) and effective partner communication. These approaches may be more effective when combined with pharmacologic therapy.
- Retrograde ejaculation and anejaculation do not require treatment unless fertility is desired.
- In the setting of retrograde ejaculation, viable sperm can be recovered from the post-ejaculate urine and used for intrauterine insemination or in vitro fertilization.
- Idiopathic hematospermia may be followed expectantly and is usually self-limited to 10 or 15 ejaculations.

BOX 2 Causes of Retrograde Ejaculation, Delayed Ejaculation, Anejaculation, and Anorgasmia

Aging Male
Degeneration of penile afferent nerves

Psychogenic
Inhibited ejaculation

Congenital
Müllerian duct cyst
Wolffian duct abnormality
Prune belly syndrome

Anatomic Causes
Transurethral resection of prostate
Bladder neck incision

Neurogenic Causes
Diabetic autonomic neuropathy
Multiple sclerosis
Spinal cord injury
Radical prostatectomy
Retroperitoneal lymph node dissection
Proctocolectomy
Bilateral sympathectomy
Abdominal aortic aneurysmectomy
Para-aortic lymphadenectomy

Infectious
Urethritis
Genitourinary tuberculosis
Schistosomiasis

Endocrine
Hypogonadism
Hypothyroidism

Medication
α-Methyldopa
Alpha blockers
Thiazide diuretics
Tricyclic and SSRI antidepressants
Phenothiazine
Alcohol abuse

SSRI, Selective serotonin reuptake inhibitor.
From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

- Delayed ejaculation or anorgasmia caused by serotonin reuptake inhibitors usually improves with withdrawal of the medication. Sexual therapy and counseling can improve these conditions if they are caused by dysfunctional sexual techniques or psychological issues. Vibratory or electrical stimulation of emission is helpful in selected cases.
- Painful ejaculation that is myofascial rather than infectious in origin may benefit from pelvic floor physical therapy.
- Fig. E1 illustrates an algorithm for the management of delayed ejaculation, anejaculation, and anorgasmia. Drug therapy for delayed ejaculation and anejaculation is summarized in Table E1.

ACUTE GENERAL Rx

- Premature ejaculation: Selective serotonin reuptake inhibitors (SSRI) (e.g., sertraline, fluoxetine) and the tricyclic antidepressant clomipramine can successfully delay ejaculation when taken daily. Dapoxetine, a short-acting SSRI, may be used as an "on-demand" treatment for premature ejaculation (not available in the U.S.). Topical anesthetics such as lidocaine cream and topical sprays have been used with variable success. A meter-dosed lidocaine-prilocaine spray gained approval for use in Europe in 2017. The use of phosphodiesterase inhibitors (PDE5i) (e.g., sildenafil, vardenafil, tadalafil) with SSRIs may be beneficial in men with concomitant erectile dysfunction and premature ejaculation. Table E2 summarizes drug therapy for premature ejaculation.
- Retrograde ejaculation: Pharmacologic therapy is only effective in patients without an anatomic disturbance of the bladder neck. Sympathomimetic medications (phenylpropanolamine, ephedrine, pseudoephedrine) and imipramine may be useful in converting retrograde ejaculation to antegrade ejaculation.
- Antimicrobial treatment for infections, NSAIDs, and muscle relaxants may help decrease discomfort associated with painful ejaculation.
- The use of the pharmacologic therapies listed above for the treatment of various disorders of ejaculation is strictly off label in the U.S. and does not carry FDA approval.
- Fig. E2 illustrates an algorithm for the office management of premature ejaculation.

CHRONIC Rx

Rarely, painful ejaculation due to long-standing obstructive causes may show improvement with surgical intervention (e.g., vasectomy reversal). The pharmacologic therapies listed above can also be used for the chronic treatment of disorders of ejaculation and orgasm.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- A variety of nutritional supplements and herbs have been used for the treatment of erectile dysfunction, but their benefit for the specific treatment of ejaculation and orgasm disorders is unknown.
- Acupuncture and traditional Chinese medicine may be helpful in treating underlying hormonal imbalances.
- Yoga and meditation can reduce the effects of stress and relieve anxiety about sexual dysfunction.
- Therapeutic massage can decrease stress.

DISPOSITION

Prognosis varies with etiology. Ejaculatory dysfunction attributable to sexual techniques, psychological issues, or pelvic floor musculature can improve with psychotherapy or physiotherapy. Pharmacologic treatment may be helpful in treating premature, retrograde, or painful ejaculation.

REFERRAL

All fertility issues and suspected anatomic problems should be referred to a urologist. Professional psychotherapy should be considered for appropriate patients.

PEARLS AND CONSIDERATIONS

COMMENTS

Ejaculatory and orgasmic disorders are common male sexual dysfunctions and include premature ejaculation, delayed ejaculation, anejaculation, retrograde ejaculation, painful ejaculation, hematospermia, and anorgasmia. Physical exam is usually normal.

PREVENTION

Preventing sexually transmitted infections and treating other inflammatory disorders of the genitourinary tract may be of some benefit in reducing the incidence of these sexual disorders.

PATIENT & FAMILY EDUCATION

These sexual disorders can exert a significant psychological burden on affected men and their partners. A combination of pharmacologic and nonpharmacologic therapies, including a urologic and psychologic evaluation, when indicated, may be helpful in the treatment of these complaints.

BOX E1 Recommended and Optional Questions to Establish the Diagnosis of Delayed Ejaculation (DE) and Direct Treatment

Recommended Questions for Diagnosis of DE

For Diagnosis

What proportion of the time can you ejaculate during sexual intercourse?
During intercourse, how long after penetration does it take for you to ejaculate?
When you cannot ejaculate during sexual intercourse, how often do you feel that you are close to ejaculation?
If you cannot ejaculate, why do you stop intercourse?
Do you ever feel that you have ejaculated, but fail to release semen?
Do you feel bothered, annoyed, and/or frustrated by your DE?
How often can you ejaculate during masturbation by yourself or with your partner?

Optional Questions

Differentiate Lifelong and Acquired DE

When did you first experience DE?
Have you experienced DE since your first sexual experience on every/almost every attempt and with every partner?

Assess Erectile Function

Is your erection hard enough for penetration?
Do you have difficulty in maintaining your erection during intercourse?
During masturbation, are you able to achieve an erection that is hard enough for penetration?
Do you wake up at night or in the morning with an erection that is hard enough for penetration?

Assess Relationship Impact

How upset is your partner with your DE?
Do you or your partner avoid sexual intercourse?
Is your DE affecting your overall relationship?

Previous Treatment

Have you received any medial or psychological treatment for your DE?

Impact on Quality of Life

Do you feel anxious, depressed, or embarrassed because of your DE?

From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

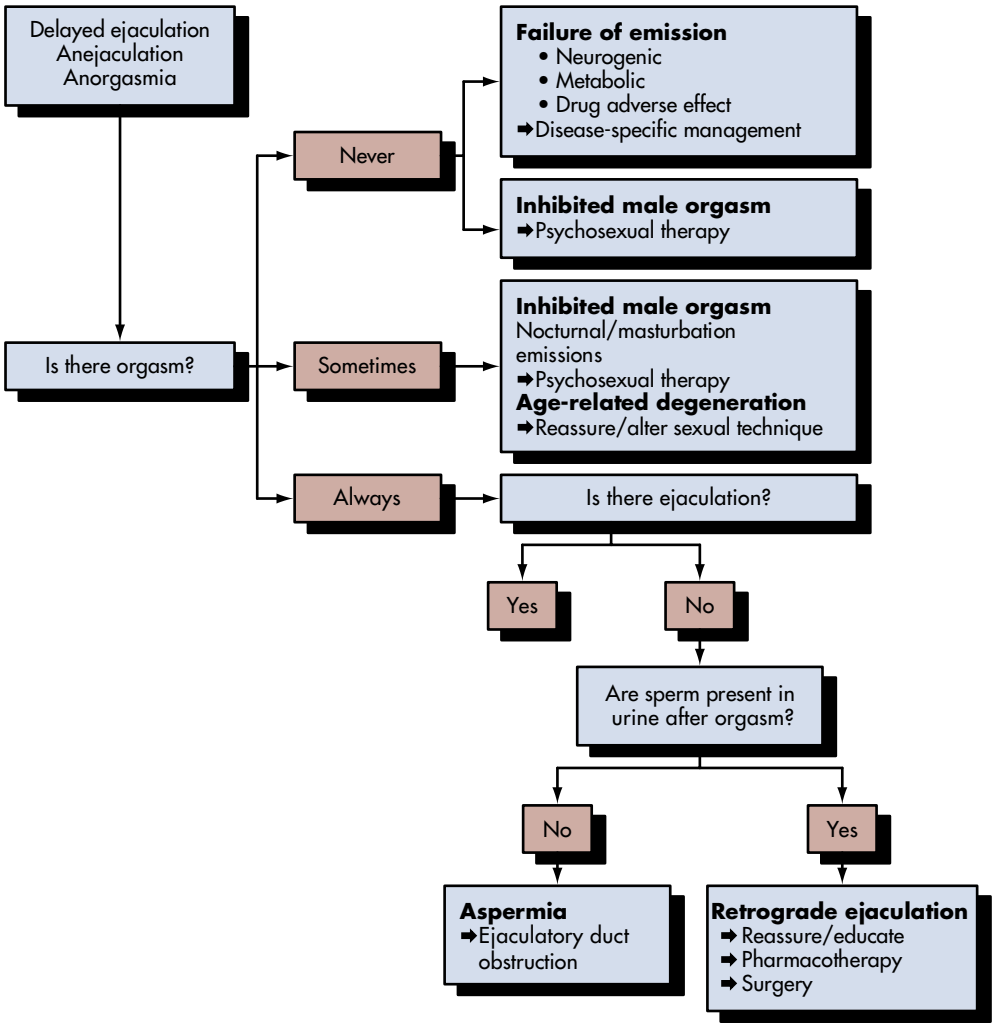

FIG. E1 Algorithm for the office management of premature ejaculation (PE). (From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.)

TABLE E1 Drug Therapy for Delayed Ejaculation and Anejaculation

	Dosage	
Drug	**As Needed**	**Daily**
Cabergoline	—	0.5-2 mg every 3 days
Amantadine	100-400 mg (for 2 days before coitus)	100-200 mg twice daily
Pseudoephedrine	60-120 mg (1-2 hr before coitus)	—
Reboxetine	—	4-8 mg
Oxytocin	24 IU intranasal during coitus	—
Bupropion	—	150 mg/day or twice daily
Buspirone	—	5-15 mg twice daily
Cyproheptadine	4-12 mg (3-4 hr before coitus)	—

From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

TABLE E2 Drug Therapy for Premature Ejaculation (PE)

Drug	Dose	Dosing Instructions	Indication	Comments	Level of Evidence
Dapoxetine	30-60 mg	On demand, 1-3 hr before intercourse	Lifelong PE Acquired PE	Approved in >50 countries	High
Paroxetine	10-40 mg	Once daily or 4-5 hours prior to sexual activity	Lifelong PE Acquired PE		High
Sertraline	50-200 mg	Once daily or 4-5 hours prior to sexual activity	Lifelong PE Acquired PE		High
Fluoxetine	20-40 mg	Once daily or 4-5 hours prior to sexual activity	Lifelong PE Acquired PE		High
Citalopram	20-40 mg	Once daily	Lifelong PE Acquired PE		High
Clomipramine	12.5-50 mg	Once daily	Lifelong PE Acquired PE		High
	12.5-50 mg	On demand, 3-4 hr before intercourse	Lifelong PE Acquired PE		High
Tramadol	25-50 mg	On demand, 3-4 hr before intercourse	Lifelong PE Acquired PE	Potential risk for opiate addiction	Low
Topical lignocaine/prilocaine	Patient titrated	On demand, 20-30 min before intercourse	Lifelong PE Acquired PE		High
Alprostadil	5-20 μg	Patient administered intracavernous injection 5 min before intercourse	Lifelong PE Acquired PE	Risk for priapism and corporal fibrosis	Very low
PDE5 inhibitors	Sildenafil 25-100 mg Tadalafil 10-20 mg Vardenafil 10-20 mg	On demand, 30-50 min before intercourse	Lifelong and acquired PE in men with normal erectile function		Very low
			Lifelong and acquired PE in men with ED	? Improved efficacy if combined with SSRI	Moderate

ED, Erectile dysfunction; *PDE5*, phosphodiesterase type 5; *SSRI*, selective serotonin reuptake inhibitor.
From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.

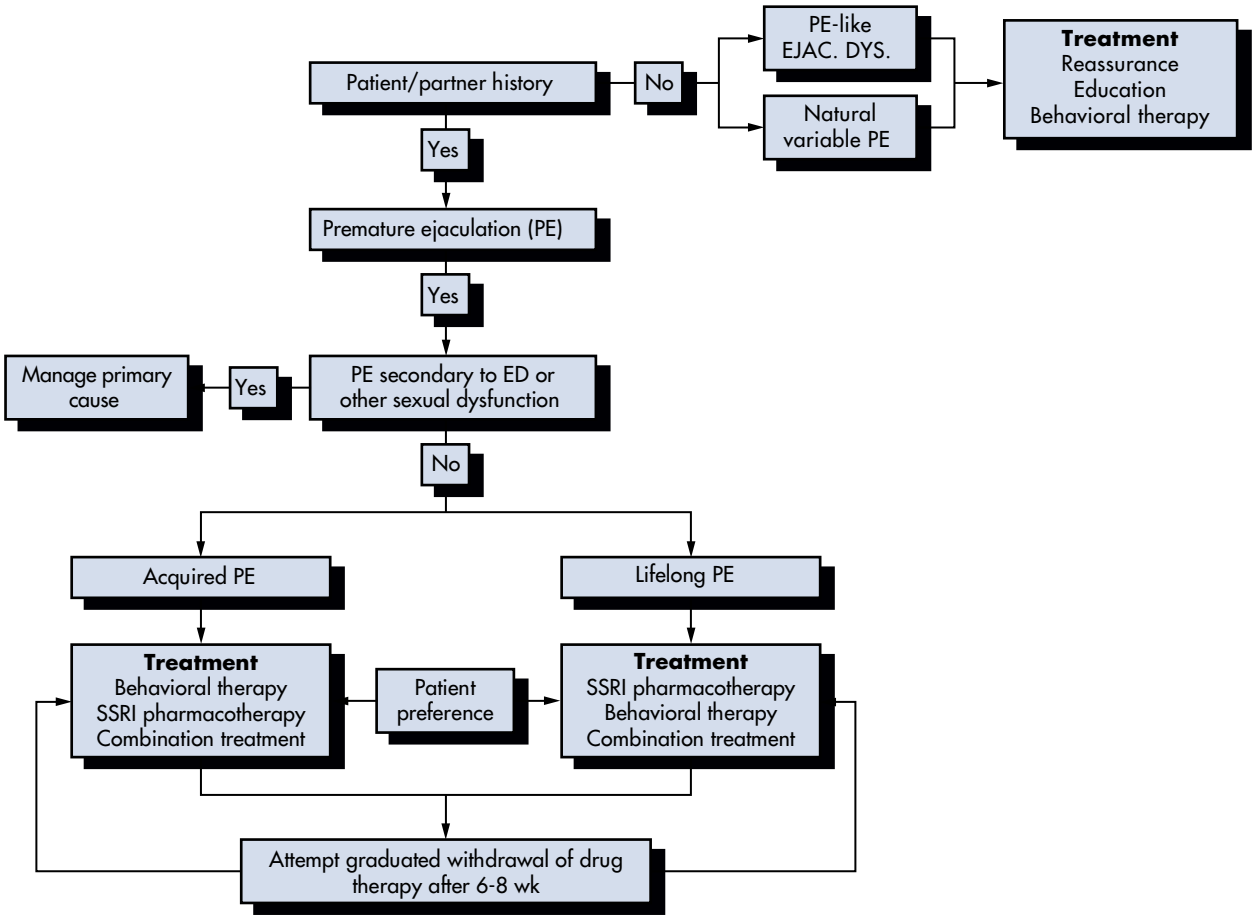

FIG. E2 Algorithm for the office management of premature ejaculation (PE). *ED*, Erectile dysfunction; *EJAC DYS*, ejaculation dysfunction; *SSRI*, selective serotonin reuptake inhibitor. (From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Elder abuse consists of actions that cause harm committed by someone in a trust relationship whether in the community or institutional setting.

- Physical abuse: Inflicting physical pain or injury
- Sexual abuse: Inflicting nonconsensual sexual activity
- Psychological abuse: Inflicting mental anguish, including intimidation, humiliation, or threats
- Financial abuse: Improper use of resources, property, or assets without the person's consent
- Neglect: Abandonment, failure to fulfill a care-taking obligation, including provision of food, safe shelter, physical health and mental health care, or basic custodial care
- Box E1 summarizes definitions of types of abuse, with examples of behavior and effects

SYNONYMS

Battered elder syndrome
Elder mistreatment
Domestic violence in the elderly
Diogenes syndrome
Intimate partner violence (IPV)

Adult abuse, neglect, and maltreatment cover a range of diagnostic codes depending on whether the issue is confirmed or suspected and whether the problem is neglect, physical, psychological, or sexual. The DSM-5 includes these codes under other conditions that may be a focus of clinical attention.

Core Codes:

ICD-10CM CODES

T74 and T76	Abuse, neglect, and other maltreatment
T74.0 and T76.0	Neglect or abandonment
T74.1 and T76.1	Physical abuse
T74.2 and T76.2	Sexual abuse
T74.3 and T76.3	Psychological abuse
T74.9 and T76.9	Unspecified adult maltreatment

DSM-5 CODES

Depends on specific diagnosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: As many as 5,000,000 elders are abused annually in the U.S.

PEAK INCIDENCE: >75 yr; more recent studies now suggest <75 yr

PREVALENCE:

- About 10% of those 60 yr or older have been abused.
- Emotional followed by financial abuse are the most common forms.
- 12-mo U.S. prevalence rates: Emotional abuse 9.0% and 4.6%; physical abuse 0.2% and 1.6%; sexual abuse 0.6%; neglect 0.5%; and financial abuse 3.5% and 5.2%.
- Family members reported 21% of nursing home residents were neglected on one or more occasion in the past 12 mo, and over 24% had been subjected to physical abuse during their entire stay.
- Among caregivers of patients with dementia in the U.K., one half reported behaving abusively at least some of the time, and one third reported "important" levels of abuse. Verbal abuse was common and physical abuse was rare.
- Elder abuse is associated with increased risk of mortality, with the highest for caregiver neglect, functional impairment, and greater emotional distress, including depression, anxiety, and posttraumatic stress.
- Adult intimate partner violence perpetrators are significantly more likely to have witnessed intimate partner violence as a child than non perpetrators.
- Older women are more likely than older men to be victims of abuse.

RISK FACTORS (VICTIM):

- Impaired cognition
- Behavioral problems
- Psychiatric illness or psychological problems
- Mental or physical dependence
- Poor physical health or frailty
- Trauma or past abuse
- Shared living situation and premorbid relationship with abuser
- Social isolation and poor social support
- Low household income

RISK FACTORS (PERPETRATOR):

- Relationship conflict with the victim
- Substance abuse, mental illness, particularly depression
- Caregiver burden or stress, being an involuntary caregiver, overwhelmed or resentful

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical abuse with multiple injuries at various stages with implausible descriptions of their origins
- Fear, hypervigilance, or withdrawal
- Evidence of poor nutrition, dehydration, poor hygiene, multiple or neglected pressure ulcers, genital or anal pain, neglected medical conditions, or evidence of restraint use (bruises around wrists or ankles)
- Toxicologic evidence of unprescribed medications
- Poor adherence, frequent no-shows, or little contact with health care system
- Caregiver not allowing interviewing the patient alone

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dementia
- Depression, substance misuse, posttraumatic stress disorder (PTSD), or other psychiatric disorder

BOX E1 Definitions of Types of Abuse, with Examples of Behavior and Effects

- **Physical abuse:** Nonaccidental infliction of physical force that results in bodily injury, pain, or impairment
  - *Examples of behavior:* Hitting, slapping, pushing, burning, physical restraint
  - *Examples of effects:* Bruises, fractures, burns, broken teeth, sprains, cuts, hair loss, bleeding from scalp, fear, anxiety, depression
- **Psychological abuse:** The persistent use of threats, humiliation, bullying, swearing and other verbal conduct, and/or of any other form of mental cruelty that results in mental or physical distress
  - *Examples of behavior:* Treating an older person as a child, blaming, swearing, intimidating, name-calling, threatening violence, isolating older person
  - *Examples of effects:* Fear, depression, confusion, loss of sleep, loss of appetite
- **Financial abuse:** Unauthorized and improper use of funds, property, or any resources of an older person
  - *Examples of behavior:* Misappropriating money, valuables, or property; forcing changes to will; denying access to personal funds
  - *Examples of effects:* Loss of money, etc., inability to pay bills, deterioration in health or standard of living, lack of amenities, unusual activity in bank accounts, signatures on documents uncertain, lack of solid arrangements for financial management, eviction or house sale notices
- **Sexual abuse:** Direct or indirect involvement in sexual activity without consent
  - *Examples of behavior*:
    - *Noncontact:* Looking, photography, indecent exposure, harassment, serious teasing or innuendo, pornography
    - *Contact:* Touching breast, genitals, anus, mouth; masturbation of either or both persons; penetration or attempted penetration of vagina, anus, mouth, with or by penis, fingers, other objects
  - *Examples of effects*: Difficulty in walking or sitting, bruises, bleeding, venereal disease, psychological trauma
- **Neglect:** Repeated deprivation of assistance needed by the older person for important activities of daily living
  - *Examples of behavior:* Failure to provide food, shelter, clothing, medical care, hygiene, personal care; inappropriate use of medication or overmedication
  - *Examples of effects:* Malnutrition, pressure ulcers, oversedation, untreated medical problems, depression, confusion

From Fillet HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

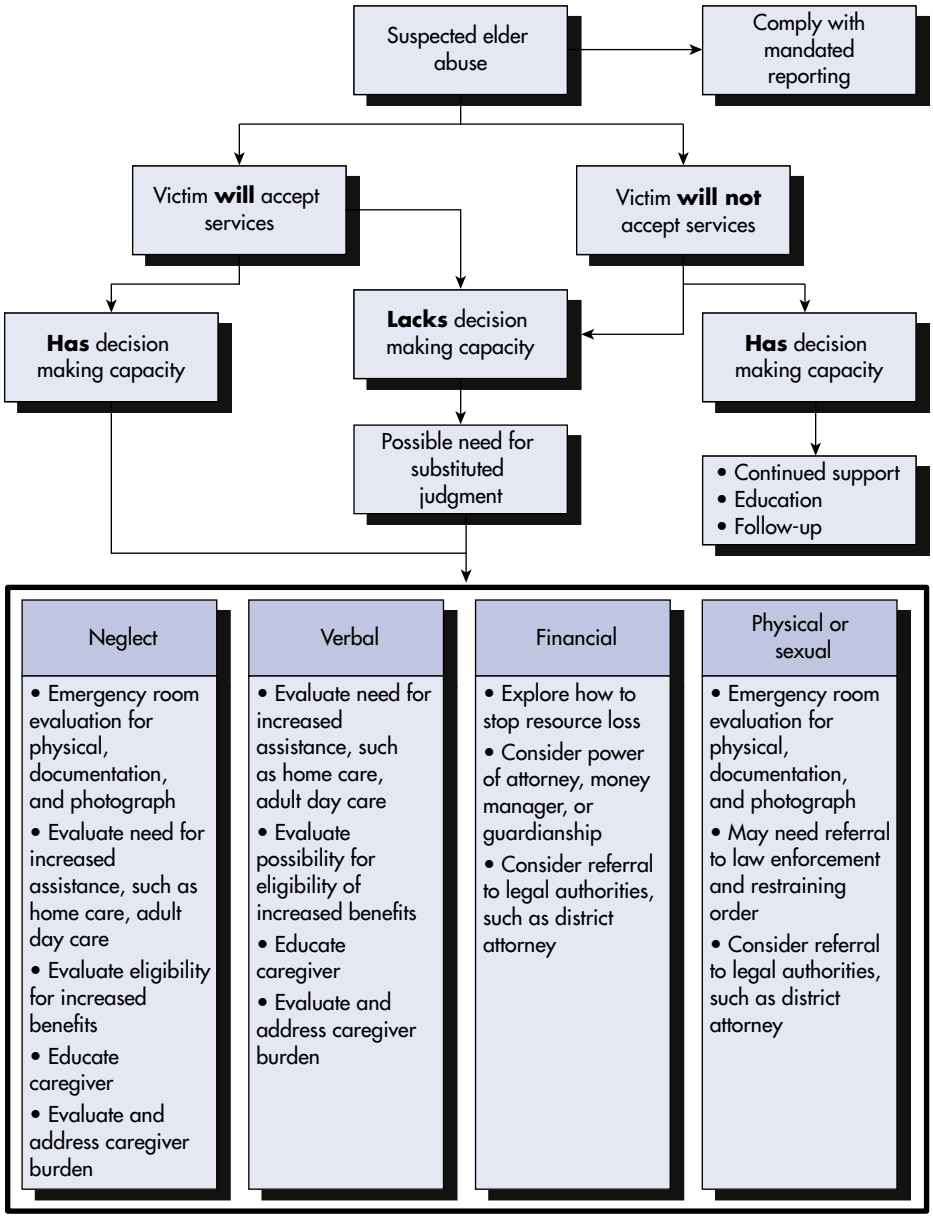

FIG. E1 Management of elder abuse. (Adapted from Kohn R, Warner J, Murphy E, Verhoek-Oftedahl W: Elder abuse. In Holzer JC, Kohn R, Recupero PR, Ellison JM [eds]: *Textbook of geriatric forensic psychiatry*, New York, 2018, Oxford University Press.)

- Malnutrition from intrinsic causes
- Nonadherence to medical treatment
- Relationship distress
- Falling

WORKUP

- Ask direct specific questions such as:
  1. "Has anyone close to you called you names or put you down recently?"
  2. "Are you afraid of anyone who lives with you or cares for you?"
  3. "Has anyone at home ever hurt you?"
  4. "Has anyone touched you without your consent?"
  5. "Has anyone forced you to do things you didn't want to do?"
  6. "Has anyone taken things or money that belong to you without your OK?"
  7. "Have you signed any documents that you don't understand?"
  8. "Are you often alone?"
  9. "When you need help has anyone ever failed to help you take care of yourself?"
  10. If appropriate, ask, "Have you been abused?"
- Interview patient and alleged perpetrator separately.
- Pelvic examination if sexual abuse suspected.
- Take photographs of physical injuries as legal evidence.

LABORATORY TESTS & IMAGING STUDIES

- Screen for dehydration, malnutrition, and rhabdomyolysis.
- Toxicology screens and therapeutic drug monitoring are sometimes helpful.
- Other tests and radiology according to presentation.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Separate patient and abuser.
- Patient and caregiver may benefit from psychiatric evaluation and treatment for substance abuse, mental illness, or cognitive impairment.
- If appropriate, assess the patient's capacity.
- Fig. E1 describes a management algorithm for elder abuse.

ACUTE GENERAL Rx

- As indicated for injury or pain relief
- As indicated for mental disorders, dementia, or delirium

DISPOSITION

If the patient's level of disability does not allow independent living, institutionalization may be required. Guidelines vary at the state and county levels regarding guardianship and conservatorship requirements.

REFERRAL

- For outpatients, report to local adult protective services agency. Reporting is mandatory in most states.
- Resident-to-resident elder mistreatment (R-REM) in nursing homes is highly prevalent. For nursing home patients, report to regional long-term care ombudsman. Reporting is mandatory under federal law.
- Mental health services may be needed.

PEARLS & CONSIDERATIONS

COMMENTS

Care should be taken in interacting with the alleged abuser so that access to the victim is not lost.

PREVENTION

- Offer social services (e.g., respite care or homecare) for stressed caregivers.
- Make financial arrangements and arrange durable power of attorney for health care and finances while patient is still cognitively intact.

Electrical and Lightning Injury PTG

BASIC INFORMATION

DEFINITION

Injuries or wounds that occur as a result of contact with an electrical current or lightning.

ICD-10CM CODES	
W87	Exposure to unspecified electric current
W86	Exposure to other specified electric current
W85	Exposure to electric transmission lines
X33	Victim of lightning
T75.4XXA	Electrocution, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

- Causes approximately 1000 deaths annually, with two thirds occurring in persons between ages 15 and 40 yr.
- Most electrical injuries in children occur at home (e.g., oral burns from electrical appliances).
- Most electrical injuries in adults are occupationally related. They rank fifth as a cause of occupational death.
- Account for 4% to 6.5% of all admissions to burn units.
- Lightning strikes kill on average 100 people annually.
  1. Eight of every 10 lightning strike victims are male; 75% of lightning deaths in the U.S. occur in the South and Midwest.
  2. 25% of lightning deaths are work related.
- Electronic weapons (stun gun and Taser) are capable of causing fatal cardiac arrhythmias.
- Table E1 compares lightning injuries with high-voltage electrical injuries.

TABLE E1 Lightning Injuries Compared with High-Voltage Electrical Injuries

Factor	Lightning	High Voltage
Energy level	30 million volts, 50,000 Å	Usually much lower*
Time of exposure	Brief, instantaneous	Seconds
Pathway	Flashover, orifice	Deep, internal
Burns	Superficial, minor	Deep, major injury
Renal	Rare myoglobinuria or hemoglobinuria	Myoglobinuric renal failure common
Fasciotomy	Rarely if ever necessary	Common, early, and extensive
Blunt injury	Explosive thunder effect	Falls, being thrown

*Range is 500 V up to millions of volts in transmission lines.
From Auerbach P: *Wilderness medicine, expert consult.* Premium Edition—Enhanced Online Features and Print, Philadelphia, 2012, Saunders.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Cognitive changes: Depending on the extent of injury, the patient may be unconscious, seizing, or confused and unable to present a history
- Extensive skin burns (>10% of the body surface):
  1. Located over the entry and exit sites (Fig. E1)
  2. Most common entry sites are the hands (Fig. E2) and skull
  3. Most common exit sites are the heels
  4. "Kissing burns" over the flexor creases
  5. Oral burns are common in children; bleeding from the labial artery may present 7 to 10 days after the injury
  6. Charring at the contact site (Figs. E3 and E4)
- Asystole or ventricular fibrillation may be the initial cardiac rhythm
- Bone fractures and periosteal burns
- Compartment syndrome from severe muscle tissue damage
- Headaches, memory disturbances
- Weakness and paresthesias
- Otologic injury, conductive hearing loss from tympanic membrane rupture or ossicular disruption
- Rhabdomyolysis and myoglobin-induced acute tubular necrosis
- Vascular injury from coagulation of small vessels or compartment syndrome

FIG. E1 The arborescent current markings on the face, neck, and anterior trunk of this young patient, which are characteristic of lightning injury, healed without the need for grafting. Note the focal lesions on the right arm, indicating the spread of the current that produced the marks on the right anterolateral aspect of the chest wall. (From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.)

- Box E1 summarizes the immediate and delayed effects of lightning injuries
- Tables E2 and E3 describe examples of acute and late direct electrical injury organ tissue dysfunction
- Table E4 compares lightning, high-voltage, and low-voltage electrical injury

ETIOLOGY

- Electricity causes tissue injury by converting electrical energy into heat or by blunt trauma from being thrown from the electrical source or from continuous muscle contraction (tetany).
- The effects of electricity are determined by seven factors: (1) type of current, (2) amount of current, (3) pathway of current, (4) duration, (5) area of contact, (6) resistance of the body, and (7) voltage.
- Tissue damage is greater with higher voltage and longer duration of contact.
- Direct current (DC) contact causes a single muscle contraction, throwing the patient away from the source. Alternating current (AC) contact precipitates a tetanic contraction, not allowing the patient to withdraw from the source and prolonging the duration of contact. AC contact is more ominous than DC contact.
- Electrical injuries are arbitrarily divided into high-voltage (>1000 volts) and low-voltage (<1000 volts) burns. Low-voltage burns involve almost exclusively either the hands or oral cavity. High-voltage injuries have a wide variety of systemic manifestations.
- The entry and exit path of the electrical current determines which tissues are affected.
- Box E2 describes the mechanisms of lightning injury.

DIAGNOSIS

WORKUP

Physical examination may not reveal the extent of damage that has occurred. Detailed testing to determine the extent of internal organ damage is indicated. In lightning injuries, male victims may have scrotal (on the undersurface of the scrotum) and penile burns, which may often be overlooked. Hemorrhage behind the eardrum with or without perforation is not uncommon. An otoscopic examination is indicated in all lightning-strike victims.

LABORATORY TESTS

- Complete blood count
- Blood chemistry profile including electrolytes
- Blood urea nitrogen and creatinine
- Arterial blood gas analysis
- Myoglobin
- Creatinine kinase with isoenzyme fractionation
- Urinalysis, including screening for myoglobinuria
- Liver function tests
- Type and cross-match
- ECG

FIG. E2 A, A farmer working in the field came in direct contact with a low-hanging wire (7000 V). **B,** An electrician grabbed a cable (270 V, alternating current) overhead to avoid falling into a ditch. **C** and **D,** A lineman touched a power line (7620 V, alternating current). (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.)

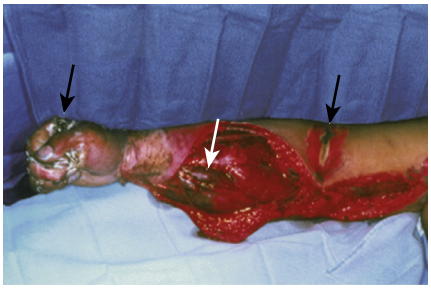

FIG. E3 Charring at the contact site in the first web space and at the site of arcing in the antecubital space *(black arrows)* of a victim of electric injury. The fixed flexion deformity of the thumb and other digits is characteristic of severe high-voltage injury to the hand and forearm. The severity of the injury is indicated by the marked edema of the forearm muscles, bulging above the cut edges of the fasciotomy incision, and the patchy dark discoloration of the muscles of the arm and the forearm, particularly the deeper muscle exposed in the central portion of the forearm incision *(white arrow).* (From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.)

FIG. E4 High-voltage electrical injury. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.)

IMAGING STUDIES

- Radiographs: Any suspicious area for bone fractures
- CT scan of the head and cervical spine in patients with suspected head injury, coma, or neurologic deficit

BOX E1 Lightning Injuries

Immediate
- Cardiac arrest and cardiac injuries
- Pulmonary injuries
- Neurologic signs
- Seizures
- Deafness
- Confusion, amnesia
- Blindness
- Dizziness
- Contusion from shock wave
- Chest pain, muscle aches
- Tympanic membrane rupture
- Headache, nausea, postconcussion syndrome

Delayed
- Neurologic symptoms and signs
- Neuropsychological changes
- Memory deficits
- Attention deficit
- Coding and retrieval problems
- Distractibility
- Personality changes
- Irritability
- Chronic pain
- Seizures

From Auerbach P: *Wilderness medicine, expert consult.* Premium Edition—Enhanced Online Features and Print, Philadelphia, 2012, Saunders.

TABLE E2 Examples of Acute, Direct Electrical Injury Organ Tissue Dysfunction

Tissue	Acute Effects
Heart	Asystole, arrhythmia, cardiac tissue necrosis (myocardium, nodal tissue, conduction pathways, coronary arteries)
Central nervous system	Brainstem dysfunction, central apnea, loss of consciousness, seizure, confusion, amnesia, cranial nerve deficits, spine fracture, paralysis or keraunoparalysis, spinal cord transection, visual and hearing disturbances, tympanic membrane rupture
Muscle	Tetany: Rhabdomyolysis, lactic acidosis, bone stress fracture, "locking-on" phenomenon

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

TABLE E3 Examples of Late Electrical Injury Organ Tissue Dysfunction

Tissue	Late Effects
Heart	Patchy cardiac tissue necrosis (myocardium, nodal tissue, conduction pathways, coronary arteries), late arrhythmias are rare
Central nervous system	Cognitive deficits, spinal cord and peripheral nerve dysfunction, cataracts
Muscle	Weakness, arthropathy, nonspecific myopathy and fibrosis, limitation of joint function
Vascular	Venous thrombosis, arterial rupture

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

TABLE E4 Comparison of Lightning, High-Voltage, and Low-Voltage Electrical Injury

	Lightning	High Voltage	Low Voltage
Voltage (V)	$>100 \times 10^6$	>1000	<1000
Current (A)	>200,000	Variable	240
Duration	Instantaneous	Brief	Prolonged
Type of current	Mostly DC	DC or AC	Mostly AC
Cardiac effect	Arrest: Asystole	Arrest: Ventricular fibrillation	Arrest: Ventricular fibrillation
Respiratory effect	Respiratory arrest: Direct CNS injury	Respiratory arrest: Indirect trauma or tetanic contractions of respiratory muscles	Respiratory arrest: Tetanic contractions of respiratory muscles
Muscle effect	Single	Contraction:DC—single AC—tetanic	Contraction: Tetanic
CNS effect	Early and delayed brain injury, coma, seizures, blindness, deafness, aphasia, cerebral vein thrombosis, late spinal cord deficits, cataracts	Early and delayed brain injury, coma, seizures, blindness, deafness, aphasia, cerebral vein thrombosis, late spinal cord deficits, cataracts	Paresthesias, transient neuropathy
Burns	Rare: Superficial ("flashover" diverts current around the body)	Common: Superficial (less) and deep (most)	Usually superficial, can be full thickness
Rhabdomyolysis	Uncommon	Very common	Common
Blunt injury	Blast effect, shock wave	Muscle contraction, fall	Fall (uncommon)
Mortality (early)	Very high (about 30%)	Moderate (about 5%-15%)	Low

AC, Alternating current; *CNS,* central nervous system; *DC,* direct current.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

BOX E2 Mechanisms of Lightning Injury

Electrothermal Effects
- Direct strike
- Contact potential
- Side flash, sometimes called "splash" (1 to 3 may include surface arcs over the body surface)
- Step voltage (also termed "Earth potential rise" or "ground current"):
  1. Transmitted through the ground
  2. Surface arcing
- Upward streamer current (also called "fifth mechanism")

Blunt Force Trauma Effects
- Barotrauma
- Concussive injury
- Musculoskeletal injury from muscle contraction, falls

From Auerbach P: *Wilderness medicine, expert consult.* Premium Edition—Enhanced Online Features and Print, Philadelphia, 2012, Saunders, Elsevier.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- At the scene: Ensure the electrical power source of injury is turned off before approaching patients
- Basic and advanced cardiac life support with cervical spine precautions. Prolonged cardiopulmonary resuscitation should be undertaken regardless of the initial cardiac rhythm
- Cardiac monitoring
- Oxygen
- Tetanus prophylaxis

ACUTE GENERAL Rx

- IV fluids to maintain urine output of 50 to 100 ml/hr (IV hydration should be reassessed with central nervous system expert in patients at risk of developing cerebral edema).
- Alkalinization of the urine (sodium bicarbonate 50 mEq in 1 L of normal saline) in patients with or at risk of myoglobinuria.
- Furosemide 20 to 40 mg PO or IV and/or mannitol 12.5 g/kg/hr may be used to force diuresis.
- Seizures are treated in the standard fashion.
- Treat burns with sulfadiazine silver dressings.
- Table E5 summarizes critical care management of the electrical injury patient in the first hour.

CHRONIC Rx

- Hospitalization is indicated in patients with high-voltage injuries, extensive burns, central nervous system symptoms, myonecrosis (creatine kinase level more than twice normal, high serum myoglobin levels, or myoglobinuria), new cardiac arrhythmia or ECG changes, or any internal organ damage.
- Ophthalmology consultation at the follow-up to screen for cataract formation (occurs

TABLE E5 Critical Care Management of the Electrical Injury Patient (First Hour)

Concern	Action	Goal
Airway (PRIORITY) Assess for: • Airway patency • Altered mental status • Facial injuries • Airway obstruction • Aspiration	1. Manual airway support as needed (e.g., clear airway, bag valve mask) 2. Intubate *early*; diffuse edema and multisystem organ dysfunction may progress quickly (surgical airway may be necessary) 3. Clinically confirm placement with examination and end-tidal CO_2 monitor (radiologic confirmation of ETT placement ASAP); well-secure ETT in place 4. Immediate C/T/L/S spine immobilization 5. Initiate pulse oximetry	• Secure airway
Breathing Assess for: • Spontaneous effort • Pneumothorax • Hemothorax • Chest wall compromise (musculoskeletal or burn) • Smoke inhalation (if associated material ignition)	1. Treat pneumothorax immediately 2. Initiate mechanical ventilation if needed 3. Correct hypoxia with supplemental O_2 (start with 100% FiO_2) 4. Check ABG 5. CXR (confirm tube placement, identify injury) 6. Consider early bronchoscopy to assess for inhalation injury if flame exposure is involved 7. Early escharotomy if needed	• *Avoid* hypoxia • SaO_2 >92% • pCO_2 35-45 mm Hg • Plateau pressure <30 mm Hg
Circulation Assess for: • Shock • Distended neck veins • Cardiac tamponade • Cardiac arrhythmia • Cardiac dysfunction • Hemorrhage • Peripheral pulses	1. BLS/ACLS/ATLS algorithms 2. Treat cardiac tamponade immediately 3. Establish adequate IV access; edema and multisystem organ dysfunction will progress quickly 4. Infuse isotonic IV fluids toward target goals 5. Continuous ECG and blood pressure monitoring 6. Place urinary catheter 7. FAST +/– focused CT to assess for hemorrhage 8. Consider central venous access for resuscitation monitoring 9. Early fasciotomy 10. Complete blood count, type and cross, cardiac enzymes, lactate	• MAP ≥60-65 mm Hg • UO ≥0.5 cc/kg/hr (if suspect rhabdomyolysis: UO >1.0 cc/kg/hr) • SvO_2 60-65 mm Hg • Lactic acid <2.0 • Closely monitor for development of pulmonary edema
Disability Assess for: • Acute brain injury • Acute spine injury • Musculoskeletal deformity	1. Assess consciousness, pupillary size and response, lateralizing signs, level of spinal cord injury 2. Assess using Glasgow Coma Score 3. Assess spine pain and gross function 4. Full neurologic examination when possible 5. Head and spine CT as needed	
Exposure Assess for: • Core temperature • Cutaneous injury	1. Warm IV fluids 2. Warm room 3. Insulating covers (if needed) 4. Burn wound area assessment 5. Cover burn sites with dry, clean linen (pending definitive burn care) 6. Splint unstable fracture sites to avoid neurovascular compromise 7. Serial, focused neurovascular checks	• *Avoid* hypothermia • Core temperature 98.6° F (37° C)
Comprehensive evaluation Assess for: • Efficacy of current treatment • Additional or missed injuries	1. Secondary and tertiary surveys per ACS trauma protocol 2. Pertinent additional studies and laboratory tests such as UA, CK-MB, troponin, ECG 3. Focused radiologic studies 4. Consider transfer to burn center	

ABG, Arterial blood gas; *ACLS,* advanced cardiovascular life support; *ACS,* American College of Surgeons; *ASAP,* as soon as possible; *ATLS,* advanced trauma life support; *BLS,* basic life support; *CK-MB,* creatine kinase-MB; *CO_2,* carbon dioxide; *CT,* computed tomography; *C/T/L/S,* cervical, thoracic, lumbar, sacral; *CXR,* chest x-ray; *ECG,* electrocardiogram; *ETT,* endotracheal tube; *FAST,* focused assessment with sonography for trauma; *FiO_2,* fraction of inspired oxygen; *IV,* intravenous; *MAP,* mean arterial pressure; *O_2,* oxygen; *pCO_2,* partial pressure of carbon dioxide; *SaO_2,* saturated oxygen; *SvO_2,* mixed venous oxygen saturation; *UA,* urinalysis; *UO,* urine output.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

within 1 to 24 mo of a high-voltage electrical injury in 5% to 20% of patients).

DISPOSITION

- Patients with severe burns should be transferred to the regional burn center.
- Complications of electrical injuries include:
  1. Infection
  2. Renal failure from rhabdomyolysis
  3. Seizure disorder
  4. Fasciotomies
  5. Amputation
- Delayed neurologic damage may present as ascending paralysis, amyotrophic lateral sclerosis, or transverse myelitis weeks to yrs after the injury.
- Vascular damage may also present in a delayed fashion.

REFERRAL

- Referrals to general surgery, burn surgery, trauma surgery, orthopedic surgery, and/or critical care specialists as appropriate in any patient that meets hospitalization criteria. Ophthalmology and ear-nose-throat specialist referral may be indicated.
- Plastic surgery is recommended in children with oral burns.

PEARLS & CONSIDERATIONS

COMMENTS

- The size of external skin burns can often underestimate the degree of internal injury.
- Lightning Strike and Electric Shock Survivors International is a support group that serves people from around the world who have sustained an electric injury (www.lightning-strike.org).
- Home safety education provided one-to-one in a clinical setting or at home, especially with the provision of safety equipment, is effective in increasing the range of safety practices.
- Box E3 describes myths regarding electrical and lightning injury commonly cited as facts in litigation.

INVESTIGATIONS

- If computed tomography (CT) and magnetic resonance imaging (MRI) scans are normal, there are no injuries.

- Negative investigations (e.g., nerve conduction study, electroencephalogram, CT, MRI) mean a victim has not sustained an electric shock.
- Neuropsychological testing is objective and easily interpreted.
- Burns of electrical origin can be distinguished on histologic examination.

REMOTE SYMPTOMS

- Remote symptoms do not exist.
- Remote symptoms are proportional to the size of the shock.
- Symptoms of the shock that are not present immediately after the shock are not related to it.
- A person getting remote symptoms was psychologically vulnerable all the time.

MISCELLANEOUS

- Litigation increases the potency of the claimed symptoms. Corollary: Resolving litigation terminates symptoms.
- Medical specialists understand electricity or lightning.
- Electrical experts can predict lightning or electrical injury.
- A diagnosis of depression, posttraumatic stress disorder, adjustment disorder, and so on negate an electrical injury causation.
- Residual current devices (RCDs) eliminate the possibility of all shocks. Corollary: A shock occurring when an RCD breaks the circuit cannot be severe.

Electrical Injury (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

BOX E3 Myths Commonly Cited as Facts in Litigation

These apply to electrical injury as well as lightning injury.

Behavior of Current in the Body

- Current seeks earth.
- Current seeks the path of lowest resistance.
- Nerve tissue is a good conductor, or alternatively, current is preferentially conducted by nerve tissue.
- When a person touches a source of potential, current flows through the skin to other parts of the skin in contact with the same conductor (i.e., current passage is local only).

The Severity of Electric Shock

Myth: If the following are absent, the shock cannot be severe and no deleterious effect can result:

- Being thrown (i.e., if a person is not thrown, the shock is not severe).
- Burns (i.e., if burns are not present, the shock is not severe).
- If the only surface change is a blister, the shock was not severe.
- Entry and exit wounds:
  1. Must be present.
  2. Demonstrate the current path.
  3. If not present, indicate no shock occurred.
- Fuses being blown (i.e., if a fuse does not blow, the shock is not severe enough to harm a victim).
- Low voltage cannot harm.
- Electroconvulsive therapy does not give long-term post–electric-shock symptoms (also false), so any other electric shock cannot be harmful.

From Auerbach P: *Wilderness medicine, expert consult.* Premium Edition—Enhanced Online Features and Print, Philadelphia, 2012, Saunders, Elsevier.

BASIC INFORMATION

DEFINITION

Emergency contraception (EC) can prevent pregnancy soon after unprotected intercourse, sexual assault, or failure or improper use of a birth control method. EC reduces the risk of pregnancy when used up to 120 hours (5 days) after unprotected sex but is more effective if used earlier.

MECHANISM: The primary mechanism of all EC pills is inhibition or delay of ovulation or follicular development. Emergency insertion of the copper IUD prevents fertilization by affecting sperm motility and viability.

EFFECTIVENESS: The copper IUD prevents 99% of expected pregnancies and should be considered the first-line option for all women of childbearing age. Oral ulipristal acetate and levonorgestrel prevent the majority of pregnancies after unprotected intercourse. Ulipristal acetate is more effective than levonorgestrel, particularly in overweight and obese patients.

SYNONYMS

Morning-after pill, postcoital contraception
EC

ICD-10CM CODES

Z30.012	Encounter for prescription of emergency contraception
Z30.09	Encounter for other general counseling and advice on contraception

EPIDEMIOLOGY & DEMOGRAPHICS

Approximately 49% of all pregnancies and more than 82% of teen pregnancies in the U.S. are unintended. An estimated 1.7 million unintended pregnancies could be prevented annually if EC use were widespread.

DIAGNOSIS

LABORATORY TESTS

- If there is doubt about whether a patient is already pregnant from intercourse that occurred more than 2 wk previously, a pregnancy test may be helpful. However, there is no need for a pregnancy test before administering EC pills. Delays in administration of the medication will reduce its efficacy. The medication in EC pills will not harm an established pregnancy.
- A pregnancy test should be performed before insertion of a copper IUD.

TREATMENT

ACUTE GENERAL Rx

- Administer EC as soon as possible after unprotected intercourse. All forms of EC reduce the risk of pregnancy when used up to 5 days after unprotected intercourse but are more effective if used earlier. EC pills function by delaying ovulation, thus it is important to counsel patients to abstain or use a barrier method for 2 wk following EC use in order to avoid a later-cycle pregnancy.
- Copper IUD for EC:
  1. Emergency insertion of the copper IUD is the most effective option for EC.
  2. Ideal for women who desire effective long-term contraception and have no contraindications to IUD insertion.
  3. A pregnancy test should be performed before IUD insertion.
  4. Requires insertion by a clinician.
  5. Some women may experience changes in bleeding patterns that are bothersome.
- Emergency contraceptive pills (see Table E1):
  1. Ulipristal acetate (Ella).
     a. Single dose 30 mg ulipristal acetate, a progesterone-receptor modulator.
     b. More effective than levonorgestrel EC. Most effect hormonal option to EC. Prescription is required.
  2. Levonorgestrel (Next Choice, Plan B One-Step):
     a. Total dose 1.5 mg levonorgestrel.
     b. A single dose is equally effective and causes no more side effects than two divided doses.
     c. Less effective in overweight and obese women (BMI >25).
     d. Available over the counter without a prescription for all ages. Providing a prescription may decrease the cost of the medication, especially for Medicaid recipients.
  3. Combined estrogen/progestin contraceptive pills:
     a. Least effective method with highest incidence of side effects.
     b. Two doses, 12 hours apart, of 100 to 120 mcg ethinyl estradiol and 0.5 to 0.6 mg of levonorgestrel (or 1.0 to 1.2 mg of norgestrel) per dose.
     c. Prescription is required, but if patient uses combined oral contraceptives, she may have the product on hand.
     d. The Emergency Contraception website provides instructions for using available combined oral contraceptive pills for EC. (See http://ec.princeton.edu/questions/dose.html#dose.)
- Side effects:
  1. Nausea: Combined estrogen-progestin EC will cause nausea in 50% of women and vomiting in 20%. Side effects resolve within 1 to 2 days. Antiemetics such as meclizine 25 mg orally are recommended 1 hour before taking combined estrogen-progestin EC. It can be used on an as-needed basis with the other EC methods.
  2. Irregular bleeding: Many patients may experience irregular bleeding from 1 wk to 1 mo after EC. Irregular bleeding is typically self-limited.
  3. Other side effects include, but are not limited to, headache, fatigue, cramping, and breast tenderness.
- Contraindications:
  1. Few contraindications to EC exist other than hypersensitivity to the product. EC pills will not affect an established pregnancy.
  2. There are no other evidence-based medical contraindications to the use of EC pills. The benefits of EC in preventing pregnancy generally outweigh the theoretical risks for women with contraindications to long-term use of combined hormonal contraception, such as thromboembolic disease, smoking after age 35 yr, heart disease, or liver disease. Non–estrogen-containing EC is preferable for all women because of better efficacy but particularly for those with any of these conditions or who are breastfeeding.

CHRONIC Rx

Because EC pills are less effective than other forms of contraception, they are not recommended as an ongoing method of contraception. The copper IUD is highly effective for EC and can be kept in place to prevent pregnancy for up to 12 yr.

DISPOSITION

After using EC, most women will have their menses within 1 to 2 wk of the expected date. If a woman's next expected menses are delayed by more than 3 wk, a pregnancy test should be performed.

PEARLS & CONSIDERATIONS

COMMENTS

- The copper IUD is the most effective form of EC and is the only method that provides users with long-term contraception.
- All forms of EC pills reduce the risk of pregnancy up to 5 days after unprotected intercourse, with ulipristal acetate being the most

TABLE E1 Emergency Contraceptive Pills Available in the United States

Emergency Contraception Pills		
Brand	**Dose**	**Dose**
Ella	1 pill	30 mg ulipristal acetate
Plan B One-Step	1 pill	1.5 mg levonorgestrel
Next Choice One Dose	1 pill	1.5 mg levonorgestrel
My Way	1 pill	1.5 mg levonorgestrel
Levonorgestrel 0.75 mg	2 pills	1.5 mg levonorgestrel

effective pill. Delayed ovulation can result in a later-cycle pregnancy, so patients should use a barrier method for 2 wk following EC pill use.
- The copper IUD is highly effective regardless of BMI. EC pills are less effective in overweight and obese women, but the weight at which they lose efficacy is unclear and may vary between women. Therefore, regardless of BMI, all EC methods should be offered to all women with appropriate counseling that some forms may be less effective with higher BMI. Ulipristal acetate is more effective than levonorgestrel, particularly in overweight and obese women.
- A pregnancy test is not necessary before administering EC pills because the medications will not harm an existing pregnancy.
- Advanced prescription of EC pills at routine visits may increase timely use of EC and does not decrease the use of more reliable means of contraception. Health care providers who speak with the pharmacist directly are more likely to ensure timely distribution of EC pills to their patients.
- Levonorgestrel EC is available in the U.S. without a prescription or proof of age.

PREVENTION

- Women should be counseled about contraceptive options and the availability of EC before it is needed.
- Patients should begin an effective method of birth control immediately after using EC. Hormonal contraceptives can be started the day after EC is administered. Abstinence or a barrier method should be used for 2 wk.
- EC should be offered to all women after sexual assault.

BASIC INFORMATION

DEFINITION

An accumulation of pus in the pleural space, most often caused by bacterial infection.

SYNONYMS

Infected pleuritis
Infected pleural effusion
Purulent pleural effusion

ICD-10CM CODES
J86 Pyothorax
A16.5 Empyema due to tuberculosis

EPIDEMIOLOGY & DEMOGRAPHICS

- Empyema is most commonly a complication of bacterial pneumonia, especially in association with pneumococcal or anaerobic infection (40% to 60% of cases of empyema)
- Occurs as a complication of thoracic surgery (<20% of cases)
- Penetrating chest trauma (4% to 10% of cases)
- Bronchopleural fistulae resulting from malignancy or lung biopsy

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- May be abrupt or chronic and insidious depending on the etiologic agent and host factors.
- Typically presents as progressive pleuritic chest pain, persistent fever, and other sustained signs and symptoms of infection.
- In anaerobic empyema, particularly that caused by the actinomycetes, the clinical picture is dominated by systemic symptoms and signs: Weight loss, malaise, and low-grade fever.
- A slowly enlarging chest wall mass.
- As a complication of thoracic trauma or surgery, empyema typically results from contamination of blood within the pleural space several days following the event.
- The physical findings of empyema are those of pleural effusion. Decreased breath sounds and dullness to percussion over the involved part of the thorax is typical. Systemic signs include fever, tachycardia, leukocytosis, and warmth and erythema over the involved area.

ETIOLOGY

Infection of the lung parenchyma spreading to pleural space caused by

- *Streptococcus pneumoniae*
- *Haemophilus influenzae*
- *Staphylococcus aureus*
- *Legionella* species
- *Mycobacterium tuberculosis*
- *Actinomyces* spp.
- A variety of oral anaerobic bacteria have been cultured in 36% to 37% of empyemas: *Bacteroides fragilis, Prevotella* species, *Fusobacterium nucleatum,* and *Peptostreptococcus* are the most common

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Uninfected parapneumonic effusion
- Lung abscess (see Fig. 1)
- Congestive heart failure
- Malignancy involving the pleura
- Tuberculous pleurisy
- Collagen vascular disease (particularly rheumatoid lung and systemic lupus erythematosus)

LABORATORY TESTS

- Complete blood count; arterial blood gas.
- Blood cultures; pleural fluid cultures.
- Pleural fluid cultures identify pathogens in only 60% of cases.
- Pleural fluid analysis in empyema has the characteristics of an exudate with a ratio of pleural fluid to serum protein >0.5 or pleural fluid to serum LDH >0.6. Characteristically, empyema fluid is grossly purulent with visible organisms on Gram stain with glucose <50 mg/dl and pH <7. These findings justify immediate drainage by chest tube or surgery because of the high risk of loculation and progressive systemic infection.

IMAGING STUDIES

- Chest x-ray (Fig. E2*A*)
- Lateral decubitus view to establish the presence of free fluid in the pleural space
- Computed tomography (Fig. E2*B*) to establish the presence of fluid loculation, underlying mass lesions, and other intrathoracic pathology

TREATMENT

NONPHARMACOLOGIC THERAPY

Prompt drainage by thoracostomy (chest tube) or open thoracotomy. Video-assisted thoracoscopic surgery (VATS) has greatly improved surgical management of empyemas.

ACUTE GENERAL Rx

- Maintenance of drainage until infection controlled.
- Antibiotics directed at suspected or proven bacterial or fungal pathogens. Initial regimens include cefotaxime or ceftriaxone for suspected *S. pneumoniae* or group A *Streptococcus,* nafcillin or oxacillin for suspected methicillin-sensitive *S. aureus,* vancomycin or linezolid for suspected MRSA, ceftriaxone for suspected *H. influenzae,* and clindamycin plus ceftriaxone when suspecting anaerobes. Other agents with excellent anaerobic coverage include carbapenem antibiotics such as meropenem and ertapenem and piperacillin/tazobactam. These agents also have excellent gram-negative coverage.
- Thoracoscopy or instillation of thrombolytic agents (streptokinase or urokinase) may be considered in refractory, loculated empyema.

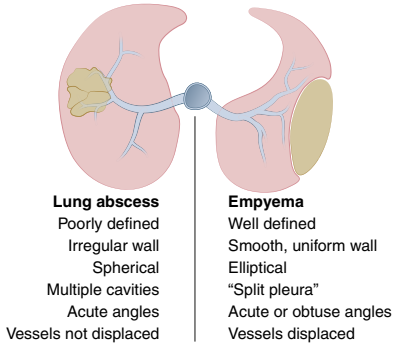

FIG. 1 Empyema versus lung abscess. (From Webb WR, Brant WE, Major NM: *Fundamentals of body CT*, ed 4, Philadelphia, 2015, Saunders.)

CHRONIC Rx

- If thorough drainage cannot be accomplished, open thoracotomy with pleural decortication may be required.
- Lung function should be monitored following completion of therapy.

DISPOSITION

Hospitalization with supplemental oxygen with ventilatory support if necessary

REFERRAL

Consultation by infectious diseases, pulmonary, or thoracic surgery specialists as needed

PEARLS & CONSIDERATIONS

COMMENTS

- Empyema caused by actinomycetes may present with erosion through the chest wall and formation of a fistulous tract.
- Nosocomial infection caused by relatively resistant bacterial or fungal pathogens may result in empyema in patients with indwelling thoracostomy tubes.

Encephalitis, Acute Viral ALG PTG

BASIC INFORMATION

DEFINITION

Acute viral encephalitis is an acute febrile syndrome with evidence of meningeal involvement and of derangement of the function of the cerebrum, cerebellum, or brain stem.

SYNONYMS

Arboviral encephalitis
Brain stem encephalitis
Acute necrotizing encephalitis
Rasmussen encephalitis
Encephalitis lethargica

ICD-10CM CODES

A86	Unspecified viral encephalitis
A83.0	Japanese encephalitis
A83.1	Western equine encephalitis
A83.2	Eastern equine encephalitis
A83.3	St Louis encephalitis
A83.4	Australian encephalitis
A83.5	California encephalitis
A83.8	Other mosquito-borne viral encephalitis
A83.9	Mosquito-borne viral encephalitis, unspecified
A84.8	Other tick-borne viral encephalitis
A84.9	Tick-borne viral encephalitis, unspecified
A85.0	Enteroviral encephalitis
A85.1	Adenoviral encephalitis
A85.2	Arthropod-borne viral encephalitis, unspecified
A85.8	Other specified viral encephalitis
A92.31	West Nile virus infection with encephalitis
B00.4	Herpesviral encephalitis
B01.11	Varicella encephalitis and encephalomyelitis
B02.0	Zoster encephalitis
B05.0	Measles complicated by encephalitis
B06.01	Rubella encephalitis
B10.01	Human herpesvirus 6 encephalitis
B10.09	Other human herpesvirus encephalitis
B26.2	Mumps encephalitis
B94.1	Sequelae of viral encephalitis
G04.00	Acute disseminated encephalitis and encephalomyelitis, unspecified
G04.81	Other encephalitis and encephalomyelitis
G04.90	Encephalitis and encephalomyelitis, unspecified
G05.3	Encephalitis and encephalomyelitis in diseases classified elsewhere

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): About 20,000 cases/yr are reported to the CDC. In 2016, there were 2149 cases of West Nile virus with 106 deaths. Each yr in the U.S. approximately seven patients are hospitalized for encephalitis per 100,000 population.

PEAK INCIDENCE: Any age, but children and older adults are more likely to have significant morbidity

PREVALENCE (IN U.S.):

- Arbovirus infections are transmitted by mosquitoes and thus cause infection when mosquitoes are active, especially summer and fall. Herpes simplex infections can occur at any time.
- Geography also plays a role (Fig. 1): Whereas Eastern equine encephalitis is more likely on the East Coast of U.S., West Nile virus has spread to 48 states. Powassan virus is more common in northern New England and Canada. La Crosse virus is more common in the upper Midwestern and mid-Atlantic and southeastern states.

PREDOMINANT SEX: Male = female

PREDOMINANT AGE: Any age

GENETICS: No specific genetic or congenital predisposition

ETIOLOGY

- Can be caused by a host of viruses (Table E1), with herpes simplex the most common virus identified.
- Arboviruses transmitted by mosquitoes include Eastern equine encephalitis, Western equine encephalitis, St. Louis encephalitis, Venezuelan equine encephalitis, California virus encephalitis, Japanese B encephalitis, La Crosse encephalitis, Murray Valley and West Nile encephalitis. Tick-borne diseases include Russian spring-summer encephalitis, Powassan encephalitis, and other lesser known agents.
- Also implicated: Rabies-causing agents, CMV, Epstein-Barr, varicella-zoster, echo virus, mumps, adenovirus, coxsackie, rubeola, and herpes viruses.
- Meningoencephalitis: Acute retroviral infection from HIV.
- In the U.S., the most commonly identified etiologies are herpes simplex virus, West Nile virus, and the enteroviruses.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Initially, fever and evidence of meningeal irritation
- Headache and stiff neck
- Later, development of signs of cortical dysfunction: Lethargy, coma, stupor, weakness, seizures, facial weakness, as well as brainstem findings
- Cerebellar findings: Ataxia, nystagmus, hypotonia, myoclonus, cranial nerve palsies, and abnormal tendon reflexes
- Patients with rabies: Hydrophobia, anxiety, facial numbness, psychosis, coma, or dysarthria
- Rarely, movement disorders, such as chorea, hemiballismus, or dystonia
- Recall of a prodromal viral-like illness (this finding is not at all uniform)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial infections: Brain abscess, toxic encephalopathies, TB
- Protozoal infections
- Behçet syndrome
- Lupus encephalitis
- Sjögren syndrome
- Multiple sclerosis
- Syphilis
- Cryptococcus
- Toxoplasmosis
- Brucellosis
- Leukemic or lymphomatous meningitis
- Other metastatic tumors
- Lyme disease
- Cat-scratch disease
- Vogt-Koyanagi-Harada syndrome
- Mollaret meningitis

WORKUP (BOX 1)

- Lumbar puncture to reveal pleocytosis, usually lymphocytic, although neutrophils may be seen early on
- Usually, elevated CSF protein
- Normal or low CSF glucose
- In herpes simplex encephalitis: RBCs and xanthochromia
- Selected tests on CSF fluid in viral encephalitis are described in Table 2
- EEG changes showing periodic high-voltage sharp waves in the temporal regions and slow wave complexes suggestive of herpes encephalitis (Fig. E2)
- CT scan and MRI (Fig. 3) to reveal edema and hemorrhage in the frontal and temporal lobes
- Temporal lobe involvement suggests herpes simplex encephalitis (Fig. E4)
- Basal ganglia and thalami are areas involved as generally seen in Eastern equine encephalitis
- With West Nile infection, MRI changes have shown changes in basal ganglia, thalami, mesial temporal structures, brain stem, and cerebellum
- Arboviral infections suspected during outbreaks in specific areas
- Rising titers of neutralizing antibodies from the acute to the convalescent stage demonstrated but often not helpful in the acutely ill patient
- Polymerase chain reaction (PCR) that amplifies DNA from the CSF for herpes simplex encephalitis
- Rarely, brain biopsy to assist in the diagnosis; viral culture of cerebral tissue obtained if biopsy done
- Classic herpetic skin lesions suggestive of herpes encephalitis
- In diagnosing arboviral encephalitis:
  1. Presence of antiviral IgM within the first few days of symptomatic disease; detected and quantified by ELISA
  2 Unusual to recover an arbovirus from the blood or CSF

LABORATORY TESTS

- Aside from the lumbar puncture, most other laboratory studies are nonspecific.
- Skin lesions and urine may be cultured for herpes simplex and CMV.

TREATMENT

ACUTE GENERAL Rx

- Supportive care, frequent evaluation, and neurologic examination

FIG. 1 Map showing the worldwide geographic distribution of encephalitis caused by arthropod-borne viruses (the "arboviruses"). (Swaiman KF et al: *Swaiman's pediatric neurology, principles and practi*ce, ed 6, Philadelphia, 2017, Elsevier.)

BOX 1 Diagnostic Algorithm

All Cases

CSF
- WBC count with differential, RBC count, protein, glucose
- Gram stain and bacterial culture
- Herpes simplex virus–1/2 PCR (if test available, consider HSV CSF IgG and IgM in addition)
- VZV PCR (sensitivity may be low; if test available, consider VZV CSF IgG and IgM in addition)
- Enterovirus PCR

Blood/Serum
- Routine blood culture
- Epstein-Barr virus (EBV) antibodies (if positive for acute infection, check CSF EBV PCR)
- Hold acute serum and collect convalescent serum 10-14 days later for paired antibody testing

Respiratory, Stool
- Enterovirus PCR (respiratory, stool)
- Enterovirus (stool)

Conditional

Host Factors
- Neonate: Herpes simplex virus–2 PCR (CSF), swabs of skin vesicles, mouth, nasopharynx, conjunctivae, and rectum (viral culture)
- ≤3 yr: Parechovirus PCR (CSF and respiratory)
- Immunocompromised: Cytomegalovirus, human herpesvirus–6/7, JC virus, human immunodeficiency virus PCR (CSF)

Season and Exposure
- Summer/fall: West Nile virus (WNV) IgM (CSF, serum), WNV IgG (paired serum), and other appropriate arboviruses as geographically relevant
- Cat (particularly if with seizures and paucicellular CSF): *Bartonella* antibody (serum)
- Animal bite exposure: Rabies test[a]
- Rodent exposure: LCM antibody (serum)
- Tick and/or camping exposure: *Rickettsia* spp., antibody (serum), *Anaplasma* phagocytophila antibody (serum)
- Swimming or diving in brackish water: *Naegleria fowleri* (wet mount)[a]
- If history of sexual activity: Herpes simplex virus–2 (CSF PCR)

Signs and Symptoms
- Psychotic component or movement disorder: Anti-NMDAR antibody (CSF and serum), and abdominal ultrasound evaluation for teratoma
- Vesicular rash: Varicella zoster virus PCR (CSF)
- Rapid decompensation (especially with bite history or foreign travel): Rabies test[a]
- Respiratory (during influenza season): Influenza PCR (respiratory)
- Diarrhea and seizure (especially young child): Rotavirus (check stool for antigen), if positive then rotavirus PCR (CSF)

Laboratory Features
- CSF protein >100 mg/dl or CSF glucose less than two-thirds peripheral glucose and/or lymphocytic pleocytosis:
  1. Mycobacterial tuberculosis: Culture (CSF, respiratory), place PPD, and check IGRA, chest radiograph, fungal culture (CSF)
  2. Fungal (specific types depend on geographic residence and/or travel to endemic areas): Culture CSF *and* check antibody and antigen
  3. *Balamuthia mandrillaris:* Contact health department/CDC for assistance with testing
- CSF eosinophilia: *Baylisascaris procyonis* antibody

Travel
- Consider consultation with public health department concerning specific diseases such as arboviruses, rabies, and other diseases

CDC, Centers for Disease Control and Prevention; *CSF,* cerebrospinal fluid; *HSV,* herpes simplex virus; *Ig,* immunoglobulin; *IGRA,* interferon gamma release assay; *LCM,* lymphocytic choriomeningitis; *NMDAR, N*-methyl-D-aspartate receptor; *PCR,* polymerase chain reaction; *PPD,* purified protein derivative; *RBC,* red blood cell; *VZV,* varicella zoster virus.

[a]Contact health department for assistance with testing.

Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

TABLE 2 Selected Tests for Viral Encephalitis

Organism/Syndrome	Test	Comment
West Nile Virus		
West Nile encephalitis	IgM in CSF	Diagnostic of CNS invasive disease or acute flaccid paralysis
Herpes Simplex Virus Type 1		
Herpes simplex encephalitis	PCR in CSF	Sensitive and specific in the acute phase
	CSF–serum antibody ratio	Useful 2 wk to 3 mo after onset
Herpes Simplex Virus Type 2		
Neonatal encephalitis	PCR in CSF	Confirmatory, high sensitivity
Relapsing meningitis	PCR in CSF	Sensitive and specific in first 3 days of illness
Varicella-Zoster Virus		
Meningoencephalitis	PCR in CSF	Confirmatory when used with clinical and spinal fluid findings; sensitivity unclear
Epstein-Barr Virus		
EBV encephalitis	PCR in CSF	Suggests CNS invasion by virus
JC virus		
Progressive multifocal leukoencephalopathy	PCR in CSF	Diagnostic but incompletely (70%) sensitive
Cytomegalovirus		
CMV ventriculitis	PCR in CSF	Sensitive and specific

CMV, Cytomegalovirus; *CNS,* central nervous system; *CSF,* cerebrospinal fluid; *EBV,* Epstein-Barr virus; *IgM,* immunoglobulin M; *PCR,* polymerase chain reaction.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2011, Saunders.

FIG. 3 Gadolinium-enhanced, T1-weighted brain magnetic resonance imaging in a teenager with herpes simplex virus encephalitis. The scan shows gadolinium enhancement in the right insular cortex *(arrows).* (From Swaiman KF et al: *Swaiman's pediatric neurology, principles and practice,* ed 6, Philadelphia, 2017, Elsevier.)

- Ventilatory assistance for patients who are moribund or at risk for aspiration
- Avoidance of infusion of hypotonic fluids to minimize the risk of hyponatremia
- For patients who develop seizures: Anticonvulsant therapy and follow-up in a critical care setting
- For comatose patients:
  1. Aggressive care to avoid decubitus ulcers, contractures, and DVT
  2. Close attention to weights, input/output, and serum electrolytes
- Acyclovir 30 mg/kg/day IV total dose divided in q8 hour intervals for 14 days for herpes simplex encephalitis
- Short courses of corticosteroids to control brain edema and prevent herniation
- In patients with suspected rabies:
  1. Human rabies immune globulin (HRIG) should be given at a dose of 20 U/kg
  2. Active immunization may be stimulated by rabies vaccine, which is grown on a human diploid cell line (HDCV) and has reduced the number of doses needed to five
  3. If suspect animal is a dog or cat and can be found, observe closely for 10 days to detect rabid behavior; any significant illness in the animal should promptly initiate humane sacrifice of the animal with the brain submitted to local or state health departments for pathology and immunologic testing for rabies. Any wild animal suspected of rabies should be humanely sacrificed, if possible, and submitted for rabies testing immediately
  4. If signs are seen, animal should be euthanized and its brain examined for signs of rabies
- No specific pharmacologic therapy for most other viral pathogens

CHRONIC Rx

Some patients may develop permanent neurologic sequelae; these patients will benefit from intensive rehabilitation programs, including physical, occupational, and speech therapy.

DISPOSITION

- Patients with suspected encephalitis of any cause should generally be admitted for initial diagnostic workup and specific treatment (if available).
- Long-term management of patients with significant neurologic sequelae from encephalitis (e.g., memory defects, depression, difficulty with organization of thoughts, movement disorders) may benefit from rehabilitation services, home care, or nursing home placement.

REFERRAL

- To a neurologist for initial workup and management
- To an infectious disease specialist for diagnostic and therapeutic plan
- To a rehabilitation service for long-term evaluation and convalescent services

PEARLS & CONSIDERATIONS

- West Nile virus encephalitis occurs primarily in elderly patients >65 yr of age.
- Rabies may occur months after contact with the rabid animal, and the exposure (especially bat rabies) may have been seemingly insignificant and even inapparent.
- Experimental therapies are worthy of consideration for some forms of viral encephalitis (e.g., immune plasma, ribavirin, interferons), and expert consultation should be obtained early on for possible treatment interventions with promising experimental therapies.

TABLE E1 Encephalitis (with a Focus on Immunocompetent Patients and Pathogens in the United States)

Etiology	Association with Encephalitis	Epidemiology	Clinical and Laboratory Hallmarks	Recommended Tests and "Pitfalls"
Viruses				
Adenovirus	Mostly anecdotal data; unclear neurotropic potential	Sporadic; children and immunocompromised persons at greatest risk	Respiratory symptoms common	Viral culture or PCR from respiratory site, CSF, or brain tissue
Eastern equine encephalitis virus	Proven neurotropic potential, but uncommon	Atlantic and Gulf U.S. states	Subclinical to fulminant; 50%-70% mortality	Serology
Enteroviruses (include coxsackieviruses and enterovirus 71)	Most common cause of encephalitis in pediatric population	Highest incidence in late summer and early fall but can occur year round; large outbreaks of enterovirus 71 infection in Asia have occurred.	Aseptic meningitis most common but also encephalitis; hand, foot, and mouth rash may be present; enterovirus 71 can cause rhombencephalitis	CSF PCR single best test but not always sensitive; to increase sensitivity of detection add serum/plasma, throat PCR, or culture.
Epstein-Barr virus	Relatively common	During acute infection	Infectious mononucleosis during acute infection, cerebellar ataxia, sensory distortion ("Alice-in-Wonderland" syndrome)	Serology and CSF PCR. Beware of PCR false-positive results (detection of low levels may represent latent infection) and false-negative results (not all cases are CSF positive).
Hendra virus	Less common	Endemic in Australia; associated with equine exposure	Nonspecific	Contact local health department or Special Pathogens Branch at CDC.
Hepatitis C	Mostly anecdotal data; unclear neurotropic potential; neurologic symptoms may be related to vasculitis	Hepatitis C–seropositive patients		CSF PCR
Herpes B virus	Proven neurotropic potential; rare	Transmitted by bite of Old World macaque	Vesicular eruption at site of bite followed by neurologic symptoms, including transverse myelitis	Culture and PCR of vesicles, CSF; contact CDC or Dr. Julia Hilliard.
Herpes simplex virus (HSV) types 1 and 2	Relatively common	HSV type 1 accounts for 5%-10% of encephalitis; typically a reactivation disease, HSV type 2 occurs in neonates.	Temporal lobe seizures (apraxia, lip smacking), olfactory hallucinations, behavioral abnormalities, but children often have extratemporal lesions as well	CSF PCR single best test, but false-negative results can occur; if HSE strongly suspected, repeat lumbar puncture within 3-7 days and recheck HSV PCR and intrathecal antibodies.
Human herpesvirus–6	Unknown, especially owing to difficult interpretation of CSF PCR false-positive results	Young children (≤2 yr) or immunocompromised patients, particularly bone-marrow-transplant recipients	May be associated with "roseola rash"	CSF PCR. Beware of false-positive findings due to chromosomal integration and latent infections.
Human metapneumovirus	Anecdotal evidence only	Newly described; almost exclusively in children	Often with associated respiratory symptoms	Respiratory tract PCR (most CSF PCR negative)
Human parechoviruses	Proven neurotropic potential but frequency unknown	Children <3 yr	In young infants periventricular white matter changes resemble hypoxic ischemic encephalopathy.	Parechovirus PCR (enterovirus PCR will not detect)
Influenza virus	Unclear neurotropic potential; good data to support flu-associated encephalopathy but unclear if encephalitis and unclear mechanism	Neurologic complications occur; sporadically reported during influenza seasons; higher numbers reported in Japan and Southeast Asia	Upper respiratory tract symptoms; CSF often acellular in 10% with bilateral thalamic necrosis	Respiratory tract culture, PCR, or rapid antigen; CSF and brain PCR infrequently positive
Japanese encephalitis virus	Relatively common (but only in endemic areas)	Mosquito-borne; most common worldwide cause of encephalitis; endemic throughout Asia; vaccine preventable	Seizures, parkinsonian features, acute flaccid paralysis variably seen. MRI classically shows thalamic and basal ganglia involvement.	CSF and serum antibodies
La Crosse virus	Relatively common	Mosquito-borne; endemic in U.S. East and Midwest; highest incidence in school-aged children	Varies from subclinical illness to seizures and coma	CSF and serum antibodies
Lymphocytic choriomeningitis virus	Rare	Highest incidence in fall and winter; rodent exposure	One of few viral causes of hypoglycorrhachia	Serology

Continued

TABLE E1 Encephalitis (with a Focus on Immunocompetent Patients and Pathogens in the United States)—cont'd

Etiology	Association with Encephalitis	Epidemiology	Clinical and Laboratory Hallmarks	Recommended Tests and "Pitfalls"
Measles virus	Less common in countries where vaccine is routinely used	Vaccine preventable; measles inclusion body encephalitis onset 1-6 mo after infection; SSPE can manifest >5 yr after infection.	Measles encephalitis nonspecific. SSPE has a subacute onset with progressive dementia, myoclonus, seizures, and, ultimately, death. EEG changes are often diagnostic.	Acute form: Measles IgM SSPE: Measles IgG in CSF and serum
Mumps virus	Less common	Vaccine preventable; used to be leading cause of encephalitis-meningitis, now rarely seen	Parotitis, orchitis, hearing loss; one of few viral causes of hypoglycorrhachia	Serology, throat swab PCR, CSF culture, or PCR
Murray Valley encephalitis virus	Less common	Highest incidence in Aboriginal children in Australia and New Guinea	Nonspecific presentation; case fatality 15%-30%	Serology (may cross react with other flaviviruses)
Nipah virus	Less common	Epidemics in Southeast Asia; contact with pigs	Myoclonus, dystonia, pneumonitis	Serology (Special Pathogens Branch, CDC)
Parainfluenza 1-4	Unknown neurotropic potential; anecdotal evidence	Worldwide	Associated with respiratory symptoms	Respiratory DFA or PCR; CSF PCR rarely positive
Parvovirus B19	Anecdotal evidence only	Sporadic cases	Variably associated with rash	IgM antibody, CSF PCR
Powassan virus	Less common	Tick-borne; endemic to New England, Canada	Nonspecific	Serology
Rabies virus	Uncommon in developed countries; relatively common in Africa, Asia, South America	Vaccine preventable; most common vector is bat (bites often unrecognized); dogs important source in developing countries; worldwide distribution	Paresthesia at site of bite Furious form: Hydrophobia, agitation, delirium, autonomic instability, coma Paralytic form: Ascending paralysis in 30% Two forms sometimes overlap	Multiple tests and assays needed for antemortem testing: Antibodies (serum, CSF), PCR of saliva or CSF, IFA of nuchal biopsy, or CNS tissue. Coordinate testing with health department.
Rotavirus	Correlation with seizures in young child but unclear association with encephalitis	Typically children; winter; vaccine preventable	Usually with diarrhea	Stool antigen, CSF PCR (CDC)
Rubella virus	Less common in countries where vaccine is routinely used	Vaccine preventable	Neurologic findings typically occur at same time as rash and fever	Serology, CSF antibodies
St. Louis encephalitis virus	Relatively common	Mosquito-borne; endemic to western U.S.; occasional outbreaks in central/eastern U.S.; highest incidence in adults >50 yr	Tremors, seizures, paresis, urinary symptoms, SIADH variably present	Serology (cross reacts with other flaviviruses)
Tick-borne encephalitis virus	Relatively common in affected geographic areas	Vaccine-preventable; transmitted via tick or ingestion of unpasteurized milk; endemic to Asia, Europe, and areas of former Soviet Union	Weakness ranging from mild paresis to acute flaccid paralysis	Serology
Vaccinia	Less common	Primarily associated with vaccination	Vaccinia rash (localized or disseminated)	CSF antibodies, serum IgM (natural infection)
Venezuelan equine encephalitis virus	Less common	Central and South America; sometimes in U.S. border states (Texas, Arizona)	Myalgias, pharyngitis, upper respiratory tract infection variably present	Serology, viral cultures (blood, oropharynx), CSF antibody
Varicella zoster virus	Relatively common	Acute infection (chickenpox) or reactivation (shingles)	Vesicular rash (disseminated or dermatome), cerebellar ataxia, large vessel vasculitis	DFA or PCR of skin lesions, CSF PCR, serum IgM (acute infection)
Western equine encephalitis virus	Less common	Onset in summer and early fall; western U.S. and Canada, Central and South America	Nonspecific	Serology
West Nile virus	Relatively common	Mosquito-borne; emerging cause of epidemic encephalitis in U.S., Europe; endemic in Middle East; highest incidence in adults >50 yr; documented transmission through organ and blood	Weakness and acute flaccid paralysis, tremors, myoclonus, parkinsonian features; MRI shows basal ganglia and thalamic lesions.	CSF IgM, serum IgM/IgG, paired serology (cross reactivity with West Nile virus and SLE)

TABLE E1 Encephalitis (with a Focus on Immunocompetent Patients and Pathogens in the United States)—cont'd

Etiology	Association with Encephalitis	Epidemiology	Clinical and Laboratory Hallmarks	Recommended Tests and "Pitfalls"
Bacteria				
Bartonella henselae and other *Bartonella* spp.	Relatively common	Often occurs after scratch or bite from kitten	Encephalopathy with seizures (often status epilepticus); peripheral lymphadenopathy; CSF is usually paucicellular.	Serology (acute usually diagnostic), PCR of lymph node; CSF PCR rarely positive
Borrelia burgdorferi	Less common	Tick-borne infection; in U.S. and mostly in New England and eastern Mid-Atlantic states	Facial nerve palsy (often bilateral), meningitis, radiculitis; may be associated with or follow erythema migrans rash.	Serology (serial EIA and Western blot), CSF antibody index, CSF PCR
Chlamydia spp.	Anecdotal evidence only	Associated with *C. psittaci* and *Chlamydophila pneumoniae*	Often with associated respiratory symptoms	NP swab, respiratory, or CSF PCR
Coxiella burnetti	Less common	Animal exposures, particularly placenta and amniotic fluid	Flulike symptoms	Serology
Ehrlichia/Anaplasma	Relatively common	Tick-borne bacteria causing human monocytic and human granulocytic ehrlichiosis (HME, HGE), respectively; HME endemic to southern and central U.S.; HGE endemic to northeastern U.S. and Midwest	Acute onset of fever and HA; rash seen in <30% of cases; leukopenia, thrombocytopenia, and elevated LFTs frequent manifestations	Morulae in white blood cells, PCR of whole blood, serology (seroconversion may occur several weeks after symptoms)
Mycoplasma pneumoniae	One of most frequently identified agents in case series but mostly anecdotal evidence	Worldwide distribution	Respiratory symptoms variably present, but pneumonia rare; often with white matter involvement consistent with ADEM	PCR of NP swab or respiratory culture, serum IgM; CSF PCR rarely positive
Mycobacterium tuberculosis	Relatively common	Most common in developing countries; disease of very young and very old or immunocompromised	Subacute basilar meningitis, lacunar infarcts, hydrocephalus; CSF often with low glucose, high protein levels; pulmonary findings often associated	CSF AFB smear, culture, PCR, respiratory cultures highly suggestive
Rickettsia rickettsii	Relatively common in affected geographic areas	Tick-borne infection in North America; highest incidence in southeast and south central U.S.	Acute onset of fever and headache; petechial rash in 85% of cases beginning 3 days after onset of symptoms	Serology (seroconversion may occur several weeks after symptoms), PCR or IHC on skin biopsy of rash
Treponema pallidum	Rare (especially in pediatrics)	Sexually transmitted disease; meningoencephalitis in early disseminated disease; progressive dementia in late disease	Protean manifestations, including temporal lobe focality (mimics HSV), general paresis, psychosis, dementia	CSF VDRL (sensitive but not specific), serum RPR with confirmatory FTA-ABS
Tropheryma whippelii	Rare (especially in pediatrics)		Progressive subacute encephalopathy, oculomasticatory myorhythmia pathognomonic; variable enteropathy, uveitis	CSF PCR, PAS-positive cells in CSF, small bowel biopsy
Protozoa				
Acanthamoeba spp.	Less common; more common in immunocompromised	Worldwide, inhalation of windblown soil	Subacute progressive	Contact CDC/Parasitology
Balamuthia mandrillaris	Less common	Worldwide (but most case reports in U.S. and South America), inhalation of windblown soil	Subacute progressive disease characterized by space-enhancing lesions, often with cranial nerve palsies and hydrocephalus (similar to tuberculosis)	Serology (research laboratories), brain histopathology, CDC laboratories Contact CDC/Parasitology for testing
Naegleria fowleri	Less common	Summer; swimming or diving in brackish water or poorly chlorinated pools	Anosmia, progressive obtundation; CSF resembles bacterial meningitis, but sterile	Mobile trophozoites on wet mount of warm CSF, brain histopathology
Toxoplasma gondii	Rare in normal hosts	Worldwide; cats definitive hosts but humans often infected via consumption of undercooked meats, unwashed produce		
Helminths				
Angiostrongylus cantonensis	Most common cause of eosinophilic meningitis worldwide; rare in U.S.	In the U.S. in Louisiana and Hawaii; South Pacific, Asia, Australia, and Caribbean	Meningitis or encephalitis; eosinophils in CSF; also associated with eosinophilic pneumonitis	Identification of worm in tissues

Continued

TABLE E1 Encephalitis (with a Focus on Immunocompetent Patients and Pathogens in the United States)—cont'd

Etiology	Association with Encephalitis	Epidemiology	Clinical and Laboratory Hallmarks	Recommended Tests and "Pitfalls"
Baylisascaris procyonis	Less common	North America, Europe, and Asia; pica, particularly near raccoon latrines	Obtundation, coma; significant CSF and peripheral eosinophilia	CSF and serum antibodies; contact CDC/Parasitology for testing
Gnasthostoma spinigerum	Relatively common in affected geographic areas	Southeast Asia, some areas of South/Central America; undercooked freshwater fish, chicken, or pork; also reported with reports of ingestion of frogs/snakes	Eosinophilic myeloencephalitis; can cause intermittent symptoms for 10-15 yr because larvae are long-lived	Identification of worm in tissues
Fungi				
Coccidioides spp.	Relatively common	Southwest U.S., northern Mexico, areas of Central and South America	Neurologic manifestations are result of disseminated disease; more often meningitis than encephalitis; CSF eosinophils sometimes seen	CSF fungal culture (but need to alert lab); CSF and serum antigen and antibody. EDTA-heat–treated antigen increases sensitivity of CSF and serum.
Histoplasma capsulatum	Relatively common	Eastern and central U.S., especially Mississippi, Ohio, and Missouri River valleys; grows on mold, bird, and bat droppings; especially found in caves, barns, or excavation areas	Neurologic manifestations are result of disseminated disease.	CSF fungal culture; CSF and serum antigen and antibody. EDTA-heat–treated antigen increases sensitivity of CSF and serum. Urine antigen
Blastomyces dermatitidis	Relatively common	Southeast, central, and midwestern U.S.; also in Canada, Africa, and India	Neurologic manifestations are result of disseminated disease.	CSF fungal culture; CSF and serum antigen and antibody. EDTA-heat–treated antigen increases sensitivity of CSF and serum.

BASIC INFORMATION

DEFINITION

Encephalopathy is a clinical syndrome of global cognitive impairment characterized by impaired arousal, inattention, and disorientation.

SYNONYMS

Acute confusional state
Altered mental status

ICD-10CM CODES

G93.40	Encephalopathy, unspecified
G93.41	Metabolic encephalopathy
G93.49	Other encephalopathy
G92	Toxic encephalopathy
E51.2	Wernicke encephalopathy
G04.30	Acute necrotizing hemorrhagic encephalopathy, unspecified
G04.31	Postinfectious acute necrotizing hemorrhagic encephalopathy
G04.32	Postimmunization acute necrotizing hemorrhagic encephalopathy
G04.39	Other acute necrotizing hemorrhagic encephalopathy
G93.49	Other encephalopathy
I67.4	Hypertensive encephalopathy
I67.83	Posterior reversible encephalopathy syndrome
J10.81	Influenza due to other identified influenza virus with encephalopathy
J11.81	Influenza due to unidentified influenza virus with encephalopathy
P91.60	Hypoxic ischemic encephalopathy [HIE], unspecified
P91.61	Mild hypoxic ischemic encephalopathy [HIE]
P91.62	Moderate hypoxic ischemic encephalopathy [HIE]
P91.63	Severe hypoxic ischemic encephalopathy [HIE]

EPIDEMIOLOGY & DEMOGRAPHICS

POINT PREVALENCE: 1.1% of adults in the general population >55 yr, 10% to 40% of hospitalized elderly, and 60% of nursing home patients >75 yr; 100,000 to 200,000 cases annually with anoxic encephalopathy

RISK FACTORS: Advanced age; cancer; AIDS; terminal illness; bone marrow transplant; postoperative state; poor nutritional status; acute or chronic cardiac, pulmonary, renal, or hepatic dysfunction; history of previous insult to the brain; epilepsy; drug abuse; alcoholism; overtreatment and undertreatment of pain; use of anticholinergics, benzodiazepines, narcotics, barbiturates, and neuroleptics

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Common to all encephalopathies is a fluctuating level of arousal, poor attention, and disorientation. Table 1 summarizes stages of encephalopathy in chronic liver disease.
- Some patients may appear agitated and others lethargic.
- Delusions (fixed false beliefs) and hallucinations are common.
- Asterixis (negative myoclonus) is common.
- Other physical findings, such as fever, ascites, jaundice, or tachycardia, may vary depending on the underlying cause of encephalopathy.
- Because toxins and metabolic disturbances are common causes of encephalopathy, the history should focus on exposure to toxins, especially medications, and symptoms suggesting a concurrent illness such as a urinary tract infection, pneumonia, sepsis, meningitis, or encephalitis. Clinical events precipitating hepatic encephalopathy in patients with cirrhosis are summarized in Box 1.

ETIOLOGY

The final common pathway of all causes of encephalopathy is widespread neuronal dysfunction from either a structural or functional cause. Many conditions are reversible and carry a good prognosis if treated in a timely manner.

- Organ failure (e.g., hepatic encephalopathy [Fig. 1], hypoxia, hypercapnia, uremia)
- Infection: Systemic (e.g., urinary tract, pneumonia, sepsis) or involving the central nervous system (e.g., meningitis, encephalitis)
- Toxin ingestion or withdrawal: Special consideration should be paid to alcohol, benzodiazepines, anticholinergics, neuroleptics, antibiotics (such as fluoroquinolones), and recreational drugs
- Metabolic disturbance: Hyperosmolar states, hypernatremia, hyponatremia, hyperglycemia, hypoglycemia, hypercalcemia, hypophosphatemia, acidosis, alkalosis, inborn errors of metabolism
- Endocrinopathy: Hyperthyroidism, hypothyroidism, Cushing syndrome, adrenal insufficiency, pituitary failure
- Neoplasm: Tumors of the central nervous system, primary or metastatic; effects of distant tumors (e.g., paraneoplastic limbic encephalitis)
- Nutritional deficiency, mostly in alcoholics and chronically ill patients, such as vitamin B_1 deficiency (Wernicke encephalopathy)
- Seizures: Postictal state, nonconvulsive status epilepticus, complex partial seizures, absence seizures
- Trauma: Concussion, contusion, subdural hematoma, epidural hematoma, diffuse axonal injury
- Vascular: Ischemic and hemorrhagic strokes, vasculitis, venous thrombosis
- Post-anoxic encephalopathy
- Psychiatric disease: Acute psychosis, depression with psychiatric features
- Acute demyelinating disease: Acute disseminating encephalomyelitis, tumefactive multiple sclerosis
- Other autoimmune diseases: Autoimmune encephalitis (e.g., anti-NMDA receptor encephalitis), lupus cerebritis, cerebral vasculitis (primary angiitis of the central nervous system or a secondary cerebral vasculitis)
- Other: Posterior reversible encephalopathy syndrome (PRES), hypertensive encephalopathy, postoperative status, sleep deprivation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis for encephalopathy is broad. It is typically helpful to distinguish toxic/metabolic causes from primary neurologic causes.

TABLE 1 Stages of Encephalopathy in Chronic Liver Disease (West Haven Criteria)

Stage	Clinical Signs
Stage I	Mental slowness, euphoria or anxiety, shortened attention span, impaired calculating ability
Stage II	Lethargy or apathy, inappropriate behavior, personality change, more obvious problems with calculations
Stage III	Lethargic, somnolent, marked confusion and disorientation, but responds to verbal stimuli
Stage IV	Coma, patient may or may not respond to noxious stimuli

Patients with chronic liver disease rarely, if ever, demonstrate cerebral edema, regardless of the stage of encephalopathy.
From Vincent JL, Abraham E, Moore FA et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.

BOX 1 Clinical Events Precipitating Hepatic Encephalopathy in Patients with Cirrhosis

Gastrointestinal hemorrhage
Infection (including spontaneous bacterial peritonitis)
Sepsis
Dehydration
Imbalance of electrolytes or acid-base
Renal failure
Drugs, toxins, medications (especially sedative-hypnotics or narcotics)
Illicit substances
Alcohol
Dietary indiscretion (excessive protein intake)

From Vincent JL, Abraham E, Moore FA et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.

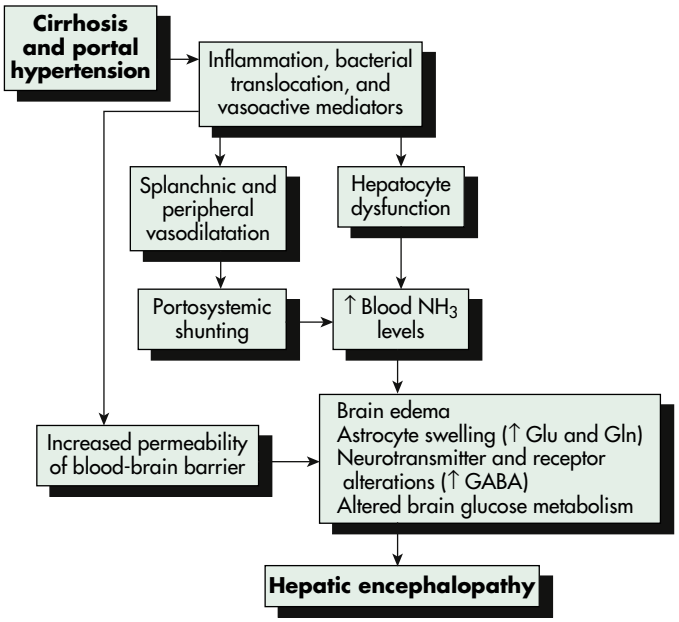

FIG. 1 Proposed pathophysiology of hepatic encephalopathy. *GABA*, Gamma-aminobutyric acid; *Gln*, glutamine; *Glu*, glutamate; *NH_3*, ammonia. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

- Dementia: Distinguished from encephalopathy by a history of slowly progressive cognitive decline over time (fluctuating cognitive function is rare except in Dementia with Lewy Bodies)
- Hypersomnia
- Aphasia: Distinguished from encephalopathy by virtue of its representing a specific disorder of language rather than a global disturbance of cognitive function
- Depression
- Psychosis: Some overlap with encephalopathy because delusions and hallucinations may be common to both
- Mania
- Vegetative state from cerebral injury; these patients appear awake (eyes are open) but there is no content to their consciousness
- Akinetic mutism: These patients do not talk and do not move; there is little fluctuation in their state, and there is no asterixis or other focal deficit
- Locked-in syndrome: May be distinguished from encephalopathy by the presence of fixed neurologic deficits (e.g., paralysis of all four limbs); however, the patient is aware of his or her environment

WORKUP

The best tool in the evaluation of encephalopathy is a good history and physical exam, which will help tailor the remainder of the diagnostic workup. Interview family members and other providers to identify preceding events, medication changes, and medical history. Evaluate focal deficits.

LABORATORY TESTS

- Comprehensive metabolic panel, amylase, lipase, ammonia, TSH, B_{12}
- Complete blood count with differential
- Drug screen and alcohol level (must order ethylene glycol separately if suspected)
- Lumbar puncture if meningitis, encephalitis, autoimmune process, or subarachnoid hemorrhage with negative imaging is suspected
- HIV, RPR
- Urinalysis and microscopy, urine culture, blood cultures
- Arterial blood gases

IMAGING STUDIES

The following imaging and diagnostic studies may be indicated depending on history and physical examination:

- Chest radiograph to rule out pneumonia
- Head CT to rule out intracranial hemorrhage, hydrocephalus, tumors
- Brain MRI with and without contrast and with diffusion-weighted images for suspected encephalitis, tumors, acute strokes, or acute autoimmune processes
- Magnetic resonance angiography/venography for strokes, arterial dissection, venous thrombosis
- Conventional angiography for CNS vasculitis and aneurysms
- EEG: Evaluate for subclinical status epilepticus

Rx TREATMENT

The encephalopathy itself is a symptom of these underlying problems. In general, it is best to avoid treating the symptom of encephalopathy with antipsychotics or sedatives. The best approach is to treat the underlying toxic or metabolic disturbance.

- Thiamine supplementation.
- Glucose for hypoglycemia.
- Antibiotics in cases of infections (choose an agent with good CNS penetration in cases of primary CNS infections; to prevent exacerbation of underlying problem, ensure also that the agent is not associated with causing encephalopathy, if possible).
- Insulin in hyperglycemic conditions (e.g., diabetic ketoacidosis, hyperosmolar nonketosis, and sepsis).
- Correct electrolyte disturbances properly.
- Treat organ failure and its sequelae; for example, implement appropriate therapy for hyperammonemia and uremia.
- Ensure hemodynamic stability (blood pressure and heart rate).
- Eliminate medications that can cause or exacerbate encephalopathy: Anticholinergic drugs, benzodiazepines and other sedative-hypnotics, neuroleptics, and narcotics.
- Consider acute intoxication with, or withdrawal from, drugs or alcohol and treat withdrawal appropriately.
- Consider serotonin syndrome and neuroleptic malignant syndrome in the appropriate clinical setting.

BASIC INFORMATION

DEFINITION/DIAGNOSTIC CRITERIA (DSM-5; ROME IV)

- Reverted passage of feces into inappropriate places (e.g., clothing, floor), whether involuntary or intentional
- At least one such event occurs each month for at least 3 mo
- The behavior is not attributable to the physiologic effects of a substance (e.g., laxatives) or another medical condition except through a mechanism involving constipation

In May 2016, Rome Foundation published the revised criteria for anorectal disorders. Encopresis is no longer named as a subclassification of functional anorectal disorders. Fecal incontinence (FI) and nonretentive fecal incontinence (NFI) are now the terms used. FI is defined as recurrent uncontrolled passage of fecal material in an individual with a developmental age of at least 4 yr for at least 3 mo. Diagnostic criteria for NFI include at least a 1-mo history of the following symptoms in a child with a developmental age older than 4 yr:

1. Defecation into places inappropriate to the sociocultural context;
2. No evidence of fecal retention;
3. After appropriate medical evaluation, the fecal incontinence cannot be explained by another medical condition.

SYNONYMS

Stool/fecal incontinence; soiling

ICD-10CM CODES

R15.9	Fecal incontinence
F98.1	Encopresis not due to a substance or known physiological condition; fecal incontinence (non-retentive) not due to an organic medical etiology

DSM-5 CODE

307.7	Encopresis with or without constipation and overflow incontinence

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Preschool age (though also occurs during school age and adolescence)
PREVALENCE (IN U.S.): 1.5% to 7.5% of children 4 to 12 yr old
PREDOMINANT SEX: More often in males (estimates range from 1.9:1 to 9:1)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most children are toilet-trained for stool by age 4. Constipation and withholding of stool are significant factors in 80% to 90% of cases ("retentive encopresis" or FI). In 10% to 20%, constipation is not a factor (NFI).
- When constipation is longstanding, soft or liquid stool may flow around the retained feces, resulting in overflow incontinence. This may occur several times per day and may mistakenly be construed as diarrhea.
- Children may report a lack of awareness of stool passage when longstanding constipation/impaction has resulted in loss of rectal tone and sensation. Furthermore, some children habituate to the odor.
- In NFI, physical examination is normal. Abdominal radiograph does not reveal fecal loading.

ETIOLOGY

- Approximately 96% of children have bowel movements between three times daily to once every other day. When bowel movements are less frequent, stool becomes drier and harder and much more uncomfortable or painful to pass. Children may avoid the discomfort or pain by avoiding elimination, resulting in worsening constipation and overflow incontinence.
- Constipation may begin gradually as a result of a decrease in elimination frequency, or more acutely after an illness or changes in diet.
- Toilet training practices that increase anxiety may also play a role in stool retention, the development of constipation, and eventual encopresis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hirschsprung disease
- Endocrine disease (hypothyroidism)
- Cerebral palsy
- Myelomeningocele
- Pseudoobstruction
- Anorectal lesions (rectal stenosis)
- Malformations
- Trauma
- Rectal prolapse
- Celiac disease
- Hypothyroidism
- Medications

WORKUP

- History: Frequency of elimination, character of the stool, associated pain, and presence of enuresis (with which it is frequently associated).
- Evaluate for other developmental or psychiatric problems.
- Common physical findings in retentive encopresis: Abdominal fecal mass, stool impacted rectum, loose anal sphincter, fecal material in the perianal area, anal tags or fissures.
- Perform a complete neurologic examination to exclude sensory-neural or spinal cord abnormalities.

LABORATORY TESTS

- Consider thyroid function tests, celiac screening tests, electrolytes, calcium, urinalysis, and urine culture.
- If concerned about the possibility of Hirschsprung disease, obtain rectal biopsy or anorectal manometry.

IMAGING STUDIES

Abdominal radiograph to determine presence of fecal impaction; MRI of spine to assess for neural tube defects or tethered cord

TREATMENT

ACUTE GENERAL Rx

- Disimpaction is a necessary first step, by oral or rectal route (or combination).
- For oral disimpaction, polyethylene glycol, magnesium citrate, or high doses of mineral oil are effective (avoid use of mineral oil in patients at risk for aspiration).
- Adding stimulant laxatives such as senna or bisacodyl can make oral disimpaction more effective.
- For rectal disimpaction, phosphate, saline, or mineral oil enemas are effective.
- When medical workup determines that constipation is not present (nonretentive encopresis/NFI), consider implementing toilet-training routines or referral to behavioral health provider.

CHRONIC Rx

- Prevent recurrence of constipation with oral stool softeners (e.g., polyethylene glycol or lactulose) or stool lubricants (mineral oil).
- In immediate post disimpaction period (1 mo after acute treatment), stimulant laxatives may be needed because bowel tone remains low; taper use as quickly as possible to avoid dependence.
- Family documentation of stool passage, including location and amount, on a chart or calendar helps inform medication changes and best times for toilet sitting.
- Praise and other small incentives for positive toileting routines and taking medication can help to maintain good bowel habits. Balanced diet and increased fiber intake/supplementation may also help.
- Formal behavioral treatment (education, reinforcement of treatment adherence and exercises to improve anal sphincter control) increases treatment success. Biofeedback to improve sphincter function is advocated by some, with 1-yr results comparable to behavioral treatment. Adjunctive Internet-based interventions that incorporate behavioral therapy and medical management are also beginning to show promise.

DISPOSITION

Encopresis may be self-limited or relatively brief in duration; may require prolonged maintenance therapy. Relapses are common.

REFERRAL

Behavioral family therapy should be considered for patients who do not respond to medical treatment within a few months or who have significant contributing psychiatric or family factors.

PEARLS & CONSIDERATIONS

- It is crucial to educate parents and children about constipation and encopresis and to defuse negative interactions.
- Emphasize that this can require prolonged maintenance therapy and that relapses are common.

AUTHORS: **Carolina S. Cerezo, MD, FAAP,** and **Wendy A. Plante, PhD**

BASIC INFORMATION

DEFINITION

Infective endocarditis is an infection of the endocardial surface of the heart or mural endocardium. Box 1 describes the modified Duke criteria for the diagnosis of infective endocarditis.

ACUTE ENDOCARDITIS: Usually caused by *Staphylococcus aureus, Streptococcus pyogenes, S. pneumoniae,* and *Neisseria* organisms; classic clinical presentation of high fever, positive blood cultures, vascular and immunologic phenomenon

SUBACUTE ENDOCARDITIS: Usually caused by viridans streptococci in the presence of valvular pathology; less toxic, often indolent presentation with lower fevers, night sweats, fatigue

ENDOCARDITIS IN INJECTION DRUG USERS: Often involving *S. aureus* or *Pseudomonas aeruginosa* with variation that may be geographically influenced; tricuspid or multiple valvular involvement; high mortality rate of 50% to 60%

PROSTHETIC VALVE ENDOCARDITIS (EARLY): Usually caused by *S. aureus* (leading cause of PVE) within 2 mo of valve replacement; other organisms include *S. epidermidis,* gram-negative bacilli, diphtheroids, *Candida* organisms

PROSTHETIC VALVE ENDOCARDITIS (LATE): Typically develops >60 days after valvular replacement; involved organisms similar to early prosthetic valve endocarditis, including viridans streptococci, enterococci, and group D streptococci

NOSOCOMIAL ENDOCARDITIS: Secondary to intravenous catheters, TPN lines, pacemakers; coagulase-negative staphylococci, *S. aureus,* and streptococci most common

Non-HACEK gram-negative bacillus endocarditis is not primarily a disease of injection drug users. More than half of all cases are associated with health care contact

SYNONYMS

Bacterial endocarditis
Subacute bacterial endocarditis (SBE)
Endocarditis

ICD-10CM CODES

I33.0 Acute and subacute infective endocarditis
I33.9 Acute endocarditis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Yearly incidence is 15 cases/100,000 persons and is increasing due to medical interventions in the elderly and an increase in implanted cardiac devices.

PEAK INCIDENCE: Females: Often <35 yr old; males: 45 to 65 yr old

NOSOCOMIAL ENDOCARDITIS: 14% to 28% of cases

PREVALENCE (IN U.S.): 0.3 to 3 cases/1000 hospital admissions. 40,000 to 50,000 new cases a yr in the U.S.

BOX 1 Modified Duke Criteria for the Diagnosis of Infective Endocarditis*

Major Criteria

- Positive blood cultures for infective endocarditis.
- Typical microorganism for infective endocarditis from two separate blood cultures in the absence of a primary focus: *Streptococcus viridans, Streptococcus bovis*
- HACEK group: *Haemophilus* species, *Actinobacillus actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens,* and *Kingella kingae*
- Community-acquired *Staphylococcus aureus* or enterococci
- Persistently positive blood cultures, defined as recovery of a microorganism consistent with infective endocarditis from blood cultures drawn more than 12 hr apart or all of three or the majority of four or more separate blood cultures, with first and last drawn at least 1 hr apart
- Single positive blood culture for *Coxiella burnetii* or antiphase IgG antibody titer >1:800
- Evidence for endocardial involvement
- TTE (TEE in prosthetic valve) showing oscillating intracardiac mass on a valve or supporting structures, in the path of regurgitant jet or on implanted material, in the absence of an alternative anatomic explanation, *or*
- Abscess, *or*
- New partial dehiscence of prosthetic valve.

Minor Criteria

- Predisposition (e.g., prosthetic valve, intravenous drug use).
- Fever: 38° C (100.4° F).
- Vascular phenomena.
- Immunologic phenomena.
- Microbiologic evidence: Positive blood culture but not meeting major criteria.

Ig, Immunoglobulin; *TEE,* transesophageal echocardiogram; *TTE,* transthoracic echocardiogram.
*Adapted from Li JS et al: Proposed modifications to the Duke criteria for the diagnosis of infective endocarditis, *Clin Infect Dis* 30:633-638, 2000.
From Ballinger A: *Kumar & Clark's essentials of clinical medicine,* ed 6, Edinburgh, 2012, WB Saunders.

PREDOMINANT SEX: Male < female
PREDOMINANT AGE: 45 to 65 yr

ENDOCARDITIS TRENDS

From 1998 through 2013 the population of patients with prosthetic valve endocarditis increased from 2% to 13.8%, as did cardiac device-related endocarditis, from 1.3% to 4.1%, whereas native valve endocarditis decreased from 74.5% to 68.4%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical manifestations of infective endocarditis are described in Table 1 and Table 2.
- Fever may be variable in presentation; may be high, hectic, or absent.
- Fever, chills, fatigue, and rigors occur in 25% to 80% of patients.
- Heart murmur may be absent in right-sided endocarditis.
- Embolic phenomenon with peripheral manifestations is found in 50% of patients.
- Skin manifestations include petechiae, Osler nodes (Fig. E1), splinter hemorrhages, Janeway lesions (Fig. E2).
- Splenomegaly is more common with subacute course.

ETIOLOGY

Staphylococcal infection is now the leading cause of native or prosthetic valve infection. Variation in incidence may occur that is influenced by the patient's risk for developing infection. Table 3 summarizes the microbiology of infective endocarditis. Risk factors include hemodialysis (8%), IV drug use (10%), mitral regurgitation (43%), aortic regurgitation (26%), and rheumatic heart disease (3.3%).

TABLE 1 Symptoms in Infective Endocarditis

Symptom	Patients Affected (%)
Fever	80-95
Chills	40-70
Weakness	40-50
Malaise	20-40
Sweats	20-40
Anorexia	20-40
Headache	20-40
Dyspnea	20-40
Cough	20-30
Weight loss	20-30
Myalgia/arthralgia	10-30
Stroke	10-20
Confusion/delirium	10-20
Nausea/vomiting	10-20
Edema	5-15
Chest pain	5-15
Abdominal pain	5-15
Hemoptysis	5-10
Back pain	5-10

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.

ACUTE ENDOCARDITIS:

- *Staphylococcus aureus* (MSSA and MRSA)
- *Staphylococcus lugdunensis*
- *Streptococcus pneumoniae*
- Streptococcal species and groups A through G
- *Haemophilus influenzae*

SUBACUTE ENDOCARDITIS:

- *Viridans streptococci* (alpha-hemolytic) including nutritionally variant species:

TABLE 2 Physical Findings in Infective Endocarditis

Finding	Patients Affected (%)
Fever	80-90
Heart murmur	75-85
New murmur	10-50
Changing murmur	5-20
Central neurologic abnormality	20-40
Splenomegaly	10-40
Petechiae/conjunctival hemorrhage	10-40
Splinter hemorrhages	5-15
Janeway lesions	5-10
Osler nodes	3-10
Retinal lesion or Roth spot	2-10

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.

1. *Abiotrophia* spp *and Granulicatella* spp;
- *S. bovis* (now called S. *gallollyticus*)
- Enterococci
- *S. aureus*

ENDOCARDITIS IN INJECTION DRUG USERS:
- *S. aureus*
- *P. aeruginosa*
- *Candida* spp.
- Enterococci

PROSTHETIC VALVE ENDOCARDITIS (EARLY):
- *S. epidermidis*
- *S. aureus*
- Gram-negative bacilli
- Group D streptococci

PROSTHETIC VALVE ENDOCARDITIS (LATE):
- *S. epidermidis*
- *Viridans streptococci*
- *S. aureus*
- Enterococci and group D streptococci

NOSOCOMIAL ENDOCARDITIS:
- Coagulase-negative staphylococci
- *S. aureus*
- Streptococci: Viridans, group B, enterococcus

HACEK ORGANISMS:
- Fastidious gram-negative bacilli
- ***H.*** *parainfluenzae*
- ***H.*** *aphrophilus*
- ***A.*** *actinomycetemcomitans*
- ***C****ardiobacterium hominis*
- ***E****ikenella corrodens*
- ***K****ingella kingae*

Other unusual pathogens:
- Q fever: *Coxiella burnetii*
- *Bartonella henselae* (etiologic agent of cat scratch disease)
- *Tropheryma whippelii* (Whipple disease)

RISK FACTORS
- Poor dental hygiene
- Long-term hemodialysis
- Diabetes mellitus
- HIV infection
- Mitral valve prolapse

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Brain abscess
- FUO
- Pericarditis
- Meningitis
- Rheumatic fever
- Osteomyelitis
- Salmonella
- TB
- Bacteremia
- Pericarditis
- Glomerulonephritis

WORKUP
Physical examination to evaluate for the previous physical findings followed by laboratory testing (see "Laboratory Tests"). Fig. 3 describes a diagnostic evaluation of suspected endocarditis. The modified Duke criteria for diagnosis of endocarditis defines "major criteria" as persistently positive blood cultures of organisms typical of endocarditis or endocardial involvement (new valvular regurgitation or positive echocardiogram). "Minor criteria" are defined as presence of predisposing condition or injection drug use, fever, embolic vascular pneumonia (e.g., glomerulonephritis, rheumatoid factor), or positive blood cultures not meeting major criteria. Definite endocarditis is two major criteria or one major criteria and three minor criteria or five minor criteria or presence of organisms by culture or histologic examination of a vegetation.

LABORATORY TESTS
- Blood cultures: Three sets in first 24 hr. Table 4 describes causes of culture-negative endocarditis.
- More culturing if patient has received prior antibiotic
- CBC (anemia possibly present, subacute)
- WBC (leukocytosis is higher in acute endocarditis)
- ESR and C-reactive protein (elevated)
- Positive rheumatoid factor (subacute endocarditis)
- Proteinuria, hematuria, RBC casts
- Serologies or PCR for more unusual pathogens (*B. henselae, C. burnetii, etc.*)

IMAGING STUDIES
- Echocardiogram: Two-dimensional. Transthoracic echocardiography (TTE) (Fig. E4) is noninvasive and more easily available but has less-than-optimal sensitivity (50% to 80%) for endocarditis.
- Transesophageal echocardiography (TEE): More sensitive in detecting vegetations and preferred diagnostic modality. It is especially helpful with prosthetic valves or in detecting perivalvular disease (Fig. E5). Echocardiographic features that suggest potential need for surgical intervention are summarized in Table 5.
- Electrocardiogram: Look for cardiac conduction abnormalities, injury pattern, or evidence of pericarditis—any such new findings are suggestive of myocardial abscess.

Rx TREATMENT

Initial IV antibiotic therapy (before culture results) is aimed at the most likely organism. The American Heart Association has developed guidelines based on the most frequently encountered bacteria. Tables 6 through 10 summarize treatment recommendations.

- **Native valve endocarditis** caused by penicillin-susceptible *S. viridians, S. gallolyticus* (previously called *S. bovis*), and other streptococci (MIC of penicillin ≤0.12 mcg/ml): Pen G 12 to 18 million U IV q24h continuous or divided q4h for 4 wk **or** ceftriaxone 2 g IV or IM q day for 4 wk for penicillin-allergic patients. Vancomycin at 30 mg/kg per 24 hr in two equally divided doses assuming normal kidney function, for 4 wk.
- **Native valve endocarditis** caused by strains of viridians streptococci and *S. gallolyticus (S. bovis)* relatively resistant to penicillin (MIC >0.12 mcg/ml): Pen G: 24 million units per 24 hr IV either continuously or in 4 or 6 equally divided doses for 4 wk **or** ceftriaxone 2 g per 24 hr IV or IM for 4 wk **plus** gentamicin 3 mg/kg per 24 hr IV or IM in one dose or in 2 to 3 equally divided doses for 2 wk or monotherapy with vancomycin 30 mg/kg per 24 hr IV in 2 equally divided doses for 4 wk not to exceed 2 g per 24 hr unless concentrations in serum too low.
- **Native valve endocarditis** due to *Staphylococcus:*
  1. **MSSA:** Nafcillin (or oxacillin) 12 per 24 hr IV in 4 or 6 equally divided doses for 6 wk **plus** optional addition of gentamicin 3 mg/kg per 24 hr IV or IM in 2 or 3 equally divided doses for 3 to 5 days **or** cefazolin 6 g per 24 hr IV in 3 equally divided doses for 6 wk, **plus** optional addition of gentamicin 3 mg/kg per 24 hr IV or IM in 2 or 3 equally divided doses for 3 to 5 days. A newer antibiotic daptomycin has an indication for right-sided endocarditis with MSSA at 6 mg/kg IV q24h.
  2. **MRSA:** Vancomycin 30 mg/kg per 24 hr in 2 equally divided doses for 6 wk; not to exceed 2 g per 24 hr unless concentrations in serum are low.
- For culture-negative native valve endocarditis one of the following regimens is suggested: Ampicillin-sulbactam: 12 g per 24 hr IV in 4 equally divided doses for 4 to 6 wk **plus** gentamicin 3 mg/kg per 24 hr IV or IM in 3 equally divided doses for 4 to 6 wk **or** vancomycin 30 mg/kg per 24 hr IV in 2 equally divided doses for 4 to 6 wk; not to exceed 2 g per 24 hr unless concentrations in serum low **plus** gentamicin 3 mg/kg per 24 hr IV or IM in 3 equally divided doses for 4 to 6 wk **plus** ciprofloxacin 1000 mg per 24 hr orally or 800 mg per 24 hr IV in 2 equally divided doses for 4 to 6 wk.
- For treatment of native valve endocarditis due to HACEK organisms: Ceftriaxone 2 g per 24

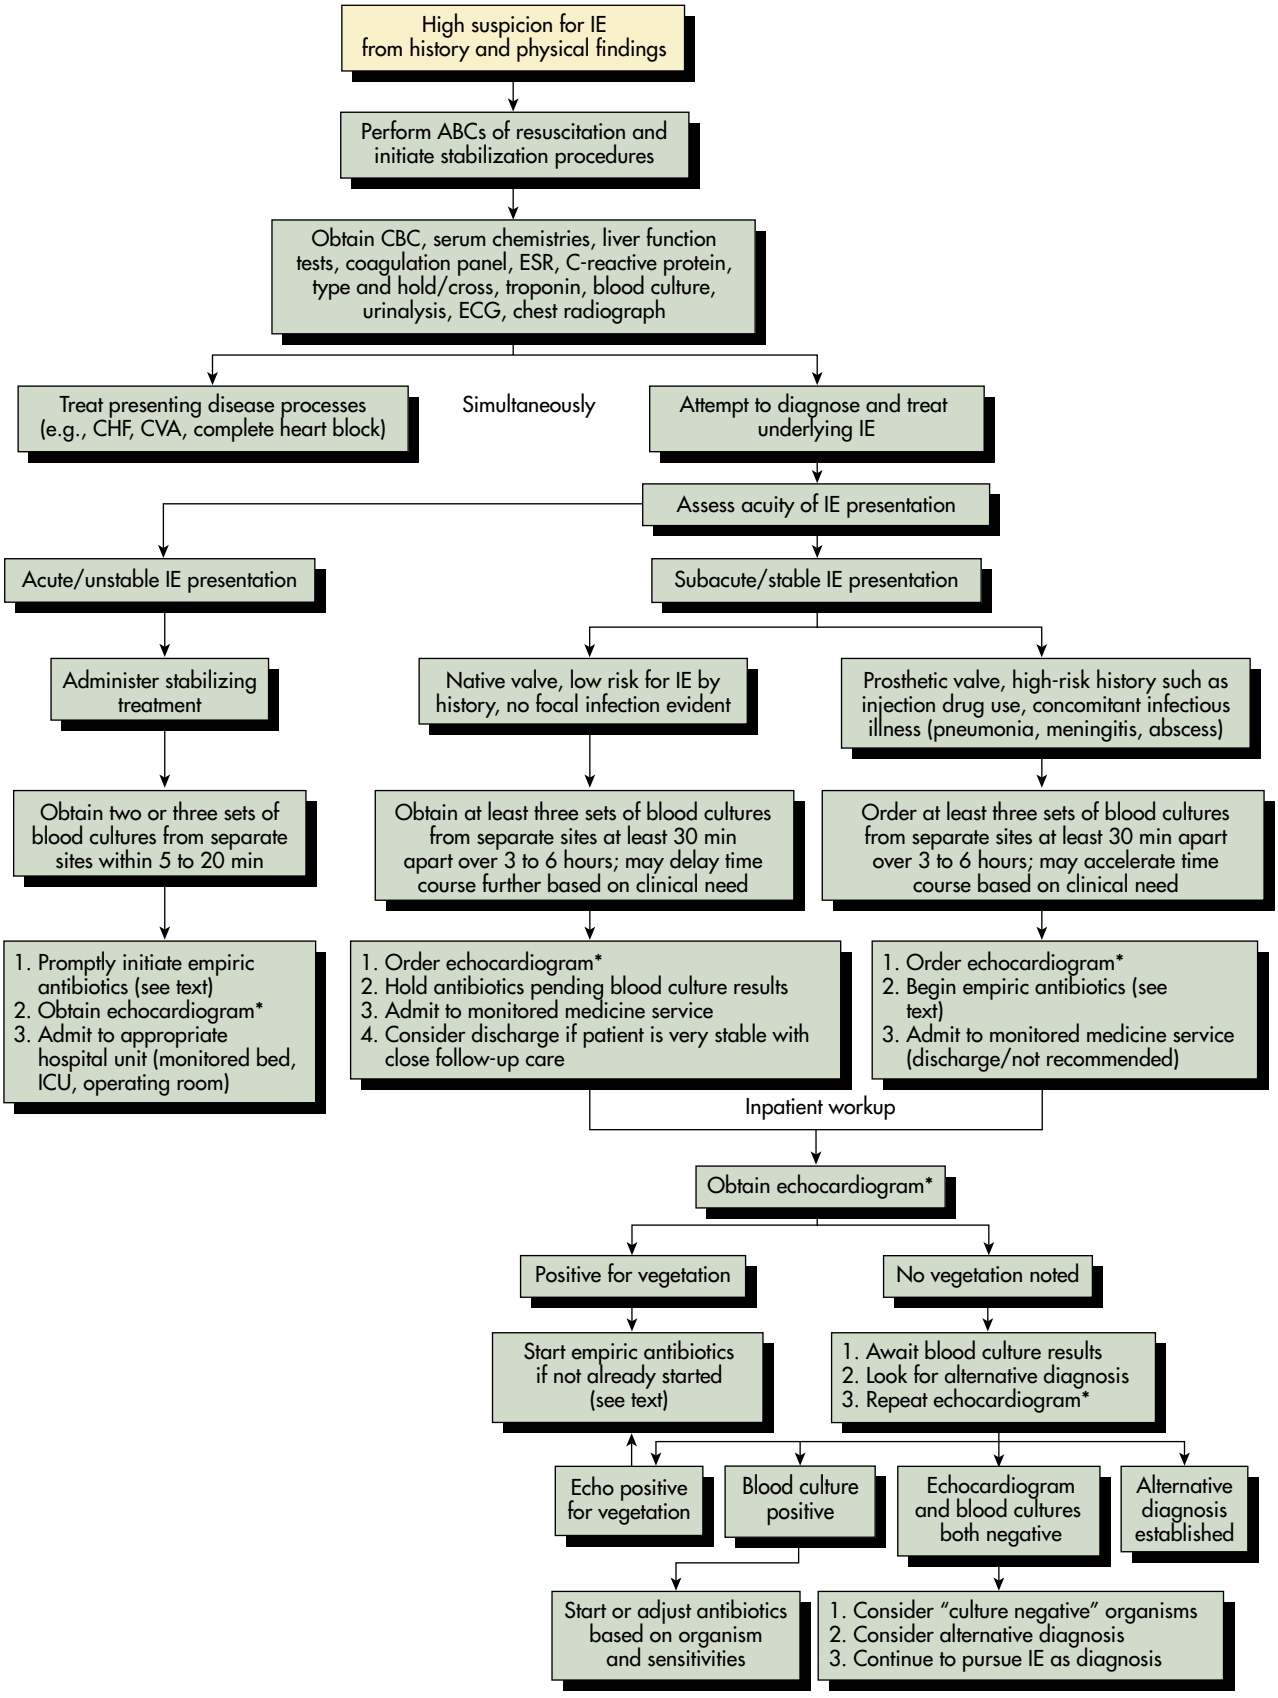

FIG. 3 Diagnostic algorithm for the emergency department management of patients in whom infective endocarditis *(IE)* is suspected. *Echocardiography can be performed via either the transthoracic *(TTE)* or transesophageal *(TEE)* technique. TEE is more invasive but is more sensitive for detecting vegetations and complications of IE, such as perivalvular abscesses; it is recommended for prosthetic valves; for situations in which optimal visualization by TTE will be difficult, such as emphysema and morbid obesity; for high suspicion of IE but normal TTE findings; and for high suspicion of a complication of IE, such as perivalvular abscess. Normal findings with either technique do not exclude IE if clinical suspicion is high. Echocardiograms can be repeated in an attempt to identify problems such as vegetations and abscesses that may not be noted initially. *ABCs,* Airway, breathing, and circulation; *CBC,* complete blood count; *CHF,* congestive heart failure; *CVA,* cerebrovascular accident; *ECG,* electrocardiogram; *ESR,* erythrocyte sedimentation rate; *ICU,* intensive care unit. (From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.)

*Formerly *Streptococcus bovis.*
HACEK, Haemophilus spp., *Aggregatibacter* spp., *Cardiobacterium hominis, Eikenella corrodens, and Kingella* spp.
From Zipes DP: *Braunwald's Heart Disease, A textbook of Cardiovascular Medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 4 Causes of Culture-Negative Endocarditis

Organism	Epidemiology and Exposures	Diagnostic Approaches
Aspergillus and other noncandidal fungi	Prosthetic valve	Lysis-centrifugation technique; also culture and histopathologic examination of any emboli
Bartonella spp.	*B. henselae:* Exposure to cats or cat fleas *B. quintana:* Louse infestation; homelessness, alcohol abuse	Most common cause of culture-negative IE in U.S.; serologic testing (may cross-react with *Chlamydia* spp.); PCR assay of valve or emboli is best test; lysis-centrifugation technique may be useful
Brucella spp.	Ingestion of unpasteurized milk or dairy products; livestock contact	Blood cultures ultimately become positive in 80% of cases with extended incubation time of 4-6 wk; lysis-centrifugation technique may expedite growth; serologic tests are available
Chlamydia psittaci	Bird exposure	Serologic tests available but exhibit cross-reactivity with *Bartonella;* monoclonal antibody direct stains on tissue may be useful; PCR assay now available
Coxiella burnetii (Q fever)	Global distribution; exposure to unpasteurized milk or agricultural areas	Serologic tests (high titers of antibody to both phase 1 and phase 2 antigens); also PCR assay on blood or valve tissue
HACEK spp.	Periodontal disease or preceding dental work	Although traditionally a cause of culture-negative IE, HACEK species are now routinely isolated from most liquid broth continuous monitoring blood culture systems without prolonged incubation times
Legionella spp.	Contaminated water distribution systems; prosthetic valves	Serology available; periodic subcultures onto buffered charcoal yeast extract medium; lysis-centrifugation technique; PCR assay available
Nutritionally variant streptococci	Slow and indolent course	Supplemented culture media or growth as satellite colonies around *Staphylococcus aureus* streak; antimicrobial susceptibility testing often requires processing specialized microbiology laboratory
Tropheryma whipplei (Whipple disease)	Typical signs and symptoms include diarrhea, weight loss, arthralgias, abdominal pain, lymphadenopathy, central nervous system involvement; IE may be present without systemic symptoms	Histologic examination of valve with periodic acid–Schiff stain; valve cultures may be done using fibroblast cell lines; PCR assay on vegetation material

HACEK, Haemophilus spp., *Aggregatibacter* spp., *Cardiobacterium hominis, Eikenella corrodens*, and *Kingella* spp.; *IE*, infective endocarditis; *PCR*, polymerase chain reaction.
From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases*, ed 8, Philadelphia, 2015, WB Saunders.

hr IV or IM in 1 dose for 4 wk **or** ampicillin-sulbactam 12 g per 24 hr IV in 4 equally divided doses for 4 wk **or** ciprofloxacin 1000 mg per 24 hr orally or 800 mg per 24 hr IV in 2 equally divided doses for 4 wk.

- **Patients with prosthetic valves** endocarditis:
- Methicillin-susceptible strains: Nafcillin or oxacillin 12 g per 24 hr IV in 6 equally divided doses for at least 6 wk **plus** rifampin 900 mg per 24 hr IV or orally in 3 equally divided doses for at least 6 wk **plus** gentamicin 3 mg/kg IV or IM in 2 or 3 equally divided doses for 2 wk.
- Methicillin-resistant strains: Vancomycin 30 mg/kg per 24 hr in two equally divided doses for at least 6 wk **plus** rifampin 900 mg per 24 hr IV or orally in three equally divided doses for at least 6 wk **plus** gentamicin 3 mg/kg per 24 hr IV or IM in two or three equally divided doses for 2 wk.

Antibiotic therapy after identification of the organism should be guided by susceptibility testing, preferably by formal testing by MIC (minimum inhibitory concentration).

TABLE 5 Echocardiographic Features That Suggest Potential Need for Surgical Intervention

Vegetation

Persistent vegetation after systemic embolization
Anterior mitral valve leaflet vegetation, particularly if it is highly mobile with size >10 mm*
One or more embolic events during the first 2 wk of antimicrobial therapy*
Increase in vegetation size despite appropriate antimicrobial therapy*†

Valvular Dysfunction

Acute aortic or mitral insufficiency with signs of ventricular failure†
Heart failure unresponsive to medical therapy†
Valve perforation or rupture†

Perivalvular Extension

Valvular dehiscence, rupture, or fistula†
New heart block†‡
Large abscess or extension of abscess despite appropriate antimicrobial therapy†

*Surgery may be required because of risk of embolization.
†Surgery may be required because of heart failure or failure of medical therapy.
‡Echocardiography should not be the primary modality used to detect or monitor heart block.
From Zipes DP: *Braunwald's Heart Disease, A textbook of Cardiovascular Medicine*, ed 11, Philadelphia, 2019, Elsevier.

TABLE 6 Therapy of Native Valve Endocarditis Caused by Highly Penicillin-Susceptible Viridans Group Streptococci and *Streptococcus gallolyticus*

Regimen	Dosage* and Route	Duration (wk)	Class	LOE	Comments
Aqueous crystalline penicillin G sodium	12-18 million U/24 hr IV either continuously or in four or six equally divided doses	4	IIa	B	Preferred in most patients >65 years of age or patients with impairment of 8th cranial nerve function or renal function
or					
Ceftriaxone sodium	2 g/24 hr IV/IM in one dose	4	IIa	B	
Aqueous crystalline penicillin G sodium	12-18 million U/24 hr IV either continuously or in six equally divided doses	2	IIa	B	2-wk regimen not intended for patients with known cardiac or extracardiac abscess or for those with creatinine clearance of <20 ml/min, impaired 8th cranial nerve function, or *Abiotrophia, Granulicatella*, or *Gemella* spp. infection; gentamicin dosage should be adjusted to achieve peak serum concentration of 3-4 μg/ml and trough serum concentration of <1 μg/ml when three divided doses are used; there are no optimal drug concentrations for single daily dosing‡
or					
Ceftriaxone sodium	2 g/24 hr IV/IM in one dose	2	IIa	B	
plus					
Gentamicin sulfate†	3 mg/kg/24 hr IV/IM in one dose	2			
Vancomycin hydrochloride§	30 mg/kg/24 hr IV in two equally divided doses, not to exceed 2 g/24 hr unless concentrations in serum are inappropriately low	4	IIa	B	Vancomycin recommended only for patients unable to tolerate penicillin or ceftriaxone; vancomycin dosage should be adjusted to a trough concentration range of 10-15 μg/ml

MIC ≤0.12 μg/ml.
IM, Intramuscular; *IV,* intravenous; *LOE*, level of evidence; *MIC,* minimum inhibitory concentration.
*Dosages recommended are for patients with normal renal function.
†Other potentially nephrotoxic drugs (e.g., nonsteroidal antiinflammatory drugs) should be used with caution in patients receiving gentamicin therapy.
‡Data for once-daily dosing of aminoglycosides for children exist, but no data for treatment of IE are available.
§Vancomycin dosages should be infused over at least 1 hr to reduce the risk of histamine-release "red man" syndrome.
From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

TABLE 7 Therapy of Native Valve Endocarditis Caused by Strains of Viridans Group Streptococci and *Streptococcus gallolyticus* Relatively Resistant to Penicillin

Regimen	Dosage* and Route	Duration (wk)	Class	LOE	Comments
Aqueous crystalline penicillin G sodium	24 million U/24 hr IV either continuously or in four to six equally divided doses	4	IIa	B	Patients with endocarditis caused by penicillin-resistant (MIC ≥0.5 μg/ml) strains should be treated with regimen recommended for enterococcal
or					
Ceftriaxone sodium	2 g/24 hr IV/IM in one dose	4	IIa	B	
plus					
Gentamicin sulfate†	3 mg/kg/24 hr IV/IM in one dose	2			
Vancomycin hydrochloride§	30 mg/kg/24 hr IV in two equally divided doses, not to exceed 2 g/24 hr, unless serum concentrations are inappropriately low	4	IIb	C	Vancomycin‡ therapy recommended only for patients unable to tolerate penicillin or ceftriaxone therapy

Minimum inhibitory concentration (MIC) >0.12 μg/ml to <0.5 μg/ml.
IM, Intramuscular; *IV,* intravenous; *LOE*, level of evidence.
*Dosages recommended are for patients with normal renal function.
†See Table 6 for appropriate dosage of gentamicin.
‡See Table 6 for appropriate dosage of vancomycin.
From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

TABLE 8 Therapy for Endocarditis of Prosthetic Valves or Other Prosthetic Material Caused by Viridans Group Streptococci and *Streptococcus gallolyticus*

Regimen	Dosage* and Route	Duration (wk)	Class	LOE	Comments
Penicillin-Susceptible Strain (MIC ≤0.12 μg/ml)					
Aqueous crystalline penicillin G sodium	24 million U/24 hr IV either continuously or in four to six equally divided doses	6	IIa	B	Penicillin or ceftriaxone together with gentamicin has not demonstrated cure rates superior to those for monotherapy with penicillin or ceftriaxone for patients with highly susceptible strain; gentamicin should not be administered to patients with creatinine clearance of <30 ml/min.
or					
Ceftriaxone	2 g/24 hr IV/IM in one dose	6	IIa	B	
with or without					
Gentamicin sulfate†	3 mg/kg/24 hr IV/IM in one dose	2			
Vancomycin hydrochloride‡	30 mg/kg per 24 h IV in two equally divided doses	6	IIa	B	Vancomycin therapy recommended only for patients unable to tolerate penicillin or ceftriaxone.
Penicillin–Relatively or Fully Resistant Strain (MIC >0.12 μg/ml)					
Aqueous crystalline penicillin sodium	24 million U/24 hr IV either continuously or in four to six equally divided doses	6	IIa	B	
or					
Ceftriaxone	2 g/24 hr IV/IM in one dose	6	IIa	B	
plus					
Gentamicin sulfate	3 mg/kg/24 hr IV/IM in one dose	6			
Vancomycin hydrochloride	30 mg/kg/24 hr IV in two equally divided doses	6	IIb	C	Vancomycin therapy is recommended only for patients unable to tolerate penicillin or ceftriaxone.

IM, Intramuscular; *IV,* intravenous; *LOE,* level of evidence; *MIC,* minimum inhibitory concentration.
*Dosages recommended are for patients with normal renal function.
†See Table 6 for appropriate dosage of gentamicin.
‡See text and Table 6 for appropriate dosage of vancomycin.
From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

TABLE 9 Therapy for Endocarditis Caused by Staphylococci in the Absence of Prosthetic Materials

Regimen	Dosage* and Route	Duration (wk)	Class	LOE	Comments
Oxacillin-Susceptible Strains					
Nafcillin or oxacillin†	12 g/24 hr IV in four to six equally divided doses	6	IIa	B	For complicated right-sided IE and for left-sided IE; for uncomplicated right-sided IE, 2 wk (see text)
For penicillin-allergic (nonanaphylactoid type) patients:					Consider skin testing for oxacillin-susceptible staphylococci and questionable history of immediate-type hypersensitivity to penicillin
Cefazolin	6 g/24 hr IV in three equally divided doses	6	IIa	B	Cephalosporins should be avoided in patients with anaphylactoid-type hypersensitivity to β-lactams; vancomycin should be used in these cases‡
Oxacillin-Resistant Strains					
Vancomycin‡	30 mg/kg/24 hr IV in two equally divided doses	6	IIa	B	Adjust vancomycin dosage to a trough serum concentration of 10-15 μg/ml (see text for vancomycin alternatives)

IE, Infective endocarditis; *IV,* intravenous; *LOE,* Level of evidence.
*Dosages recommended are for patients with normal renal function.
†Penicillin G 24 million U/24 hr IV in four to six equally divided doses may be used in place of nafcillin or oxacillin if strain is penicillin-susceptible (MIC ≤0.1 μg/ml) and does not produce beta-lactamase.
‡For specific dosing adjustment and issues concerning vancomycin, see Table 6 footnotes.
From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

DISPOSITION

- The patient may need outpatient IV antibiotic therapy, and arrangements need to be made to ensure safe vascular access and continuity of care with outpatient IV therapy team.
- Long-term follow-up is essential after therapy has ended; relapse of endocarditis may occur.
- Prophylaxis with antibiotics will be needed before dental procedures as a previous episode of endocarditis increases the risk of recurrent endocarditis associated with transient bacteremia from dental procedures.

REFERRAL

- To an infectious disease specialist.
- To a cardiologist or a cardiac surgeon if evidence of heart failure, refractory infection, myocardial abscess, valve disruption, or major embolic events occur.
- The timing and indications for surgical intervention to prevent systemic embolism in infective endocarditis remain controversial. Trials have shown that early surgery in patients with infective endocarditis and large vegetations significantly reduced death and embolic events by decreasing the risk of systemic embolism.

TABLE 10 Therapy for Endocarditis of Prosthetic Valves or Other Prosthetic Material Caused by Staphylococci

Regimen	Dosage* and Route	Duration (wk)	Class	LOE	Comments
Oxacillin-Susceptible Strains					
Nafcillin or oxacillin	12 g/24 hr IV in six equally divided doses	≥6	IIa	B	Penicillin G 24 million U/24 hr IV in four to six equally divided doses may be used in place of nafcillin or oxacillin if strain is penicillin susceptible (MIC ≤ 0.1 μg/ml) and does not produce beta-lactamase; vancomycin should be used in patients with immediate-type hypersensitivity reactions to beta-lactam antibiotics (see Table 6 for dosing guidelines); cefazolin may be substituted for nafcillin or oxacillin in patients with nonimmediate hypersensitivity reactions to penicillins
Plus					
Rifampin	900 mg/24 hr IV/PO in three equally divided doses	≥6			
Plus					
Gentamicin†	3 mg/kg/24 hr IV/IM in two or three equally divided doses	2			
Oxacillin-Resistant Strains					
Vancomycin	30 mg/kg/24 hr in two equally divided doses	≥6	IIa	B	Adjust vancomycin to achieve a trough serum concentration of 10-15 μg/ml (see text for gentamicin alternatives)
plus					
Rifampin	900 mg/24 hr IV/PO in three equally divided doses	≥6			
plus					
Gentamicin	3 mg/kg/24 hr IV/IM in two or three equally divided doses	2			

IM, Intramuscular; *IV,* intravenous; *LOE,* level of evidence; *MIC,* minimum inhibitory concentration; *PO,* oral.
*Dosages recommended are for patients with normal renal function.
†Gentamicin should be administered in close proximity to vancomycin, nafcillin, or oxacillin dosing.
From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

PEARLS & CONSIDERATIONS

- Serologies and/or PCR exist for more unusual zoonotic causes of endocarditis such as *Bartonella henselae* (cat exposure), *Coxiella burnetii* (farm animals), *Brucella* spp (unpasteurized milk or cheese), and *Tropheryma whipllei* (soil and farm animals).
- 1-yr mortality has not improved and remains at 30%.

COMMENTS

- For endocarditis prophylaxis refer to Section V.
- In regards to antibiotic prophylaxis before dental procedures in patients with orthopedic implants, the 2013 guidelines from the American Academy of Orthopedic Surgeons (AAOS) and the American Dental Association (ADA) advises clinicians to consider discontinuing the practice of routinely prescribing prophylactic antibiotics for patients with hip and knee prosthetic joint implants undergoing dental procedures.
- *Streptococcus viridians* are a large group of commensal bacteria that are either alpha hemolytic on blood agar plates or nonhemolytic. Common members of this family include *S. mutans*, *S. anginosus*, *S. mitis*, *S. sanguis*, *S. oralis,* and *S. salivarius.* These tend to be oral/dental flora and most highly penicillin susceptible.
- Recent European trials have shown that in patients with endocarditis in the left side of the heart who were in stable condition, changing to oral antibiotic treatment was noninferior to continued intravenous antibiotic treatment.[1] Additional trials will be necessary before changing current parenteral antibiotic guidelines to include oral antibiotic regimens.

Endometrial Cancer ALG PTG

BASIC INFORMATION

DEFINITION

Endometrial carcinoma (EC) is the malignant transformation of endometrial glands with stromal invasion. The changes are typified by irregular nuclear membranes, nuclear atypia, mitotic activity, loss of glandular pattern, loss of intervening stroma, and irregular cell size. The two main histologic subcategories of EC (Table 1), low-grade endometrioid (type 1) and high-grade endometrioid and nonendometrioid EC (type 2), show unique molecular aberrations and differing clinical behaviors.

SYNONYMS

Uterine cancer (some forms)
Carcinoma of the endometrium
EC

ICD-10CM CODES

C54.1 Malignant neoplasm of endometrium
C54.9 Malignant neoplasm of corpus uteri, unspecified
C55 Malignant neoplasm of uterus, part unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: In 2015, 53,911 new cases of uterine cancer were diagnosed. This corresponds to an incidence of 27 cases per 100,000 women. Incidence was greater among white and black women compared with American Indian/Alaska Native, Hispanic, and Asian Pacific Islander women. It is the most common gynecologic malignancy in the U.S. A woman's lifetime risk for development of endometrial cancer is between 2% and 3%.

PREDOMINANCE: Median age at diagnosis: 62 yr; only 5% occur in women <40 yr; 5-yr survival >80%

RISK FACTORS: Obesity, diabetes, nulliparity, early menarche and late menopause, unopposed estrogen therapy, tamoxifen use, oligoovulation with chronic unopposed estrogen exposure such as with polycystic ovary syndrome (PCOS), endometrial atypical hyperplasia, endometrial polyps (malignancy is found in 3.6% of endometrial polyps), family history. Other risk factors include a personal history of ovarian, breast, or colonic cancer, as well as certain genetic syndromes, such as Lynch syndrome and Cowden syndrome. The relative risk for endometrial cancer is summarized in Table 2.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Abnormal uterine bleeding or postmenopausal bleeding in 90%
- Pyometra or hematometra
- Abnormal Pap smear: Endometrial cells, atypical glandular cells, or adenocarcinoma
- Incidental finding at hysterectomy

ETIOLOGY

Endogenous or exogenous chronic unopposed estrogen stimulation of the endometrium

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Endometrial atypical hyperplasia
- Other genital tract malignancy
- Uterine polyps
- Atrophic vaginitis
- Granulosa cell tumor
- Fibroid uterus
- Adenomyosis

WORKUP

- Complete history and physical examination
- Endometrial biopsy or dilation and curettage (Table 3)
- Assessment of operative risk
- Staging (Tables 4, 5, and 6)

TABLE 1 Pathogenetic Subsets of Endometrial Carcinoma

Parameter	Type I	Type II
Age	50s-60s	60s-70s
Obesity	Common	Uncommon
Estrogenic stimuli	Common	Uncommon
Endometrium	Anovulatory	Atrophic
Precursor	Endometrial intraepithelial neoplasia	Presumed EmGD
Transition	Slow	Unknown
Type	Endometrioid	Papillary serous or mixed
Molecular genetics	MSI, *PTEN* mutation; loss of PAX2	p53 mutation, 1p deletions; loss of PAX2
Familial	Hereditary nonpolyposis colonic cancer syndrome	
Spread	Lymph nodes	Peritoneum
Concurrent ovarian	Common	Uncommon
Prognosis	Good	Poor

EmGD, Endometrial glandular dysplasia; *MSI,* microsatellite instability.
From Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

TABLE 2 Risk Factors for Endometrial Cancer

Factor	Relative Risk
Overweight (lb):	
• 20-50	3.0
• 50+	10.0
Nulliparous:	
• vs. one child	2.0
• vs. five children	5.0
Late menopause (>52 vs. 49 yr)	2.4
Diabetes mellitus	2.7
Unopposed estrogen therapy	6.0
Tamoxifen therapy	2.0
Sequential oral contraceptives	7.0
Combination oral contraceptives	0.5
Cowden syndrome (*PTEN* mutation)	Three- to fivefold increased risk
Hereditary nonpolyposis colonic cancer syndrome	40%-60% lifetime risk
Family member with endometrial cancer	3.4

From Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

TABLE 3 Differential Diagnosis of Endometrial Carcinoma (Curettings)

Parameter	Mimicking	Differential Diagnosis
Gland architecture	Cancer	Telescoping artifact; stromal collapse breakdown; sectioning artifacts
	Benign	Microglandular mucinous carcinoma; surface endometrioid carcinoma
Nuclear atypia	Cancer	Surface or glandular repair; Arias-Stella changes (hormonal therapy); radiation effect
Papillary changes	Cancer	Exfoliation artifact; stromal breakdown with papillary changes; papillary syncytial changes
	Benign	Papillary mucinous carcinoma

From Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

Grade 1	VBT and/or pelvic RT
Grade 2	Pelvic RT and VBT
Grade 3	Pelvic RT and VBT ± chemotherapy
Stage III_A	Chemotherapy ± pelvic RT or tumor-directed RT ± chemotherapy or pelvic RT ± VBT
Stage III_B-III_C	Chemotherapy and/or tumor-directed RT
Stage IV_A-IV_B	Chemotherapy ± RT

ARF, Adverse risk factors (age, positive lymphovascular space invasion, tumor size, lower uterine or cervical involvement); *RT,* radiation therapy; *VBT,* vaginal brachytherapy.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 5 Revised FIGO Staging for Endometrial Cancer (Adopted 2009)

Stages*	Characteristic
I	Tumor confined to the corpus uteri
I_A	No or less than half myometrial invasion
I_B	Invasion equal to or more than half of the myometrium
II	Tumor invades cervical stroma but does not extend beyond the uterus†
III	Local or regional spread of the tumor
III_A	Tumor invades serosa of the corpus uteri or the adnexa‡
III_B	Vaginal or parametrial involvement‡
III_C	Metastases to pelvic or paraaortic lymph nodes‡
III_{C1}	Positive pelvic nodes
III_{C2}	Positive paraaortic lymph nodes with or without positive pelvic lymph nodes
IV	Tumor invades bladder or bowel mucosa, or distant metastasis
IV_A*	Tumor invasion of bladder or bowel mucosa
IV_B	Distant metastases, including intraabdominal or inguinal lymph nodes

*G1, G2, or G3.
†Endocervical glandular involvement should be considered only as stage I and no longer as stage II.
‡Positive cytology has to be reported separately without changing the stage.
FIGO, Fédération Internationale de Gynécologie et d'Obstétrique (International Federation of Gynecology and Obstetrics).
From Lobo RA et al: *Comprehensive gynecology,* ed 7, Philadelphia, 2017, Elsevier.

- Fig. 1 is a diagnostic algorithm for diagnosing endometrial carcinoma for women with abnormal uterine bleeding

LABORATORY TESTS

- Complete blood count
- Prothrombin time and partial thromboplastin time if bleeding is heavy
- Chemistry profile including liver function tests
- Consider CA-125 level

IMAGING STUDIES

- Chest x-ray
- CT scan if concern for metastatic disease, and/or pelvic ultrasound (Fig. E2)
- Transvaginal ultrasound (Fig. E3) in postmenopausal women with vaginal bleeding

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Surgery is the mainstay of treatment, with or without adjuvant radiation and/or chemotherapy, depending on tumor histology, stage, and grade. Laparoscopic surgery for early-stage EC is as safe and effective as laparotomy. Robotic laparoscopy procedures have increased significantly in recent yrs for this indication.
- Surgery generally consists of pelvic washings, total hysterectomy and bilateral salpingo-oophorectomy, selective pelvic and periaortic lymphadenectomy, and omental biopsy depending on stage, grade, and histology.
- Brachytherapy and/or teletherapy are added in an advanced stage.
- Chemotherapy (carboplatin, paclitaxel) may be used for patients with high-risk endometrial cancer. Hormonal therapy (progestins alone or in combination with tamoxifen, selective estrogen-receptor modulators, aromatase inhibitors, synthetic steroid derivatives, and gonadotropin-releasing hormone analogues) may also be considered in cases where palliation, rather than cure, is the main intent of treatment, or in patients with multiple coexisting medical conditions who may not be surgical candidates.
- Hormonal therapy, commonly a levonorgestrel intrauterine device, is an option for some young women with early-stage, low-grade EC who wish to preserve fertility. This choice should be discussed with a gynecologic oncologist.

ACUTE GENERAL Rx

- A thorough workup should be completed before any therapy for EC.
- Surgery hysterectomy with bilateral salpingo-oophorectomy is the treatment of choice.

CHRONIC Rx

- Physical and pelvic examination every 3 mo for 2 yr, then every 6 mo for 2 yr, and annually thereafter with imaging as clinically indicated
- Hormone replacement (combination) a consideration in low-risk patients (stage I or early stage II)

DISPOSITION

- Survival is generally defined by the stage of the disease and histology.
- The majority of cases present early, and the 5-yr survival is generally good (Fig. E4).
- Some histologic types (clear cell, papillary serous) have worse survival rates, as they tend to be more aggressive with higher rates of metastatic disease at the time of diagnosis.

PEARLS & CONSIDERATIONS

Any woman with postmenopausal bleeding or abnormal uterine bleeding with risk factors for endometrial cancer needs evaluation by a gynecologist and either endometrial biopsy and/or pelvic ultrasound. When endometrial cancer is diagnosed, the patient should be cared for by a gynecologic oncologist and undergo surgical staging in a minimally invasive procedure when possible.

BASIC INFORMATION

DEFINITION

Endometriosis is defined as the presence of functioning endometrial glands and stroma outside the uterine cavity. It is a chronic, estrogen-dependent condition that causes dysmenorrhea and pelvic pain.

ICD-10CM CODES

N80.0	Endometriosis of uterus
N80.1	Endometriosis of ovary
N80.2	Endometriosis of fallopian tube
N80.3	Endometriosis of pelvic peritoneum
N80.4	Endometriosis of rectovaginal septum and vagina
N80.5	Endometriosis of intestine
N80.6	Endometriosis in cutaneous scar
N80.8	Other endometriosis
N80.9	Endometriosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Endometriosis affects 10% of reproductive-aged women.
- Women with dysmenorrhea: 40% to 60%.
- Subfertile women: 28% to 50%.
- Incidence peaks at approximately 40 yr.

MOST COMMON AGE AT DIAGNOSIS: 25 to 29 yr.

GENETICS:

- Familial association: If first-degree relative is affected, the patient has a seven- to tenfold increased risk of having the disease.
- Polygenic-multifactorial inheritance pattern.
- 6.9% occurrence rate in first-degree female relatives.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Classic triad is dysmenorrhea, dyspareunia, and infertility.
- Presence of pelvic pain does not correlate with the total area of endometriosis (stage of disease), type of lesion, or volume of disease but is correlated with the depth of infiltration.
- Other symptoms include abnormal bleeding (premenstrual spotting, menorrhagia), cyclic abdominal pain, intermittent constipation/diarrhea, dyschezia, dysuria, hematuria, and urinary frequency.
- Rare manifestations: Catamenial hemothorax, bloody pleural effusion, massive ascites occurring during menses.
- Most severe discomfort is associated with lesions >1 cm in depth.
- Bimanual examination may reveal tender uterosacral ligaments, cul-de-sac nodularity, induration of the rectovaginal septum, fixed retroversion of the uterus, adnexal mass, and generalized or localized tenderness.

ETIOLOGY

- Reflux and direct implantation theory: Retrograde menstruation with implantation of viable endometrial cells to surrounding pelvic structures (Sampson theory)
- Coelomic metaplasia theory: Transformation of multipotential cells of the coelomic epithelium into endometrium-like cells
- Vascular dissemination theory: Transport of endometrial cells to distant sites by the uterine vascular and lymphatic systems
- Autoimmune disease theory: Disorder of immune surveillance allows growth of endometrial implants

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ectopic pregnancy
- Acute appendicitis
- Chronic appendicitis
- Pelvic inflammatory disease (PID)
- Pelvic adhesions
- Hemorrhagic cyst
- Hernia
- Irritable bowel syndrome
- Uterine leiomyomata
- Adenomyosis
- Nerve entrapment syndrome
- Interstitial cystitis

WORKUP

- Thorough history and physical examination including ultrasound.
- Definitive diagnosis of endometriosis can be made only by histologic confirmation during surgery (gold standard).
- Fig. 1 illustrates a diagnostic and management algorithm for endometriosis.

SURGICAL STAGING

- American Society for Reproductive Medicine classification system for endometriosis (ASRM revised 1996) is the most widely accepted staging system.
- Value: Uniform recording of operative findings.
- Limitations
  1. Not a good predictor of successful pregnancy after treatment.
  2. Does not correlate well with the symptoms of pain, dyspareunia, or infertility.

Stage I	Minimal
Stage II	Mild
Stage III	Moderate
Stage IV	Severe

LABORATORY TESTS

Cancer antigen 125 (CA125): Limited overall value in the diagnosis of endometriosis

- Also elevated in ovarian epithelial neoplasm, myomas, adenomyosis, acute PID, ovarian cysts, pancreatitis, chronic liver disease, menstruation, and pregnancy.
- CA125 value >35 U/ml: Positive predictive value of 0.58 and a negative predictive value of 0.96 for the presence of endometriosis.

IMAGING STUDIES

- Ultrasound: For evaluating adnexal mass; ultrasound characteristics may suggest endometriomas versus other benign or malignant ovarian conditions but persistent solid or cystic-solid ovarian masses require definitive tissue diagnosis with laparoscopy.
- MRI:
  1. Highly accurate in detecting endometriomas.
  2. Limited sensitivity in detecting diffuse pelvic endometriosis, especially if sessile lesions.
- CT scan may show adnexal masses of varying density (Fig. 2).

TREATMENT

NONPHARMACOLOGIC THERAPY

Expectant management (observation for 5 to 12 mo) for stage I or stage II endometriosis-associated infertility. Evaluation should take place if the couple meets the diagnostic criteria for infertility.

ACUTE GENERAL Rx

Nonsteroidal antiinflammatory drugs for symptomatic relief of dysmenorrhea.

CHRONIC Rx

PHARMACOLOGIC MANAGEMENT:

Estrogen-progesterone:

- State of "pseudopregnancy" created by continuous (discarding pill pack when placebo pills remaining and starting active pills from new pill pack) use of combination oral contraceptives for minimum of 6 mo and continuing indefinitely.

Progestins:

- Medroxyprogesterone acetate 10 to 30 mg orally qd and occasionally up to 100 mg orally qd.
- Alternatively, 100 mg IM q2wk for four doses, followed by 200 mg IM monthly for 4 mo.
- Comparison with danazol: Progestins cost less, have a more tolerable side-effect profile, and have comparable efficacy with regard to pain relief and so are often the first-line drug. Very little justification for the use of danazol.

Gonadotropin-releasing hormone (GnRH) agonists:

- Induces medical menopause.
- Use usually limited to 6 to 12 mo due to hypoestrogenic effects such as osteopenia or osteoporosis but can be given longer in certain circumstances, particularly when paired with estrogen add-back therapy. Referral to specialist strongly advised.
- Elagolix is an oral GnRH antagonist that provides partial to nearly full estrogen suppression. Dosage is 150 mg once daily or 200 mg twice daily. It is effective in improving dysmenorrhea and nonmenstrual pain, but is associated with hypoestrogenic side effects (hot flashes, hyperlipidemia, decreased bone density).
- Leuprolide acetate depot 3.75 mg IM monthly or 11.25 mg IM q3mo or nafarelin 400 mcg nasal puffs bid or goserelin 3.6 mg SC monthly.
- Add-back therapy for protection against vasomotor symptoms and bone loss: Norethindrone acetate 5 mg PO qd alone

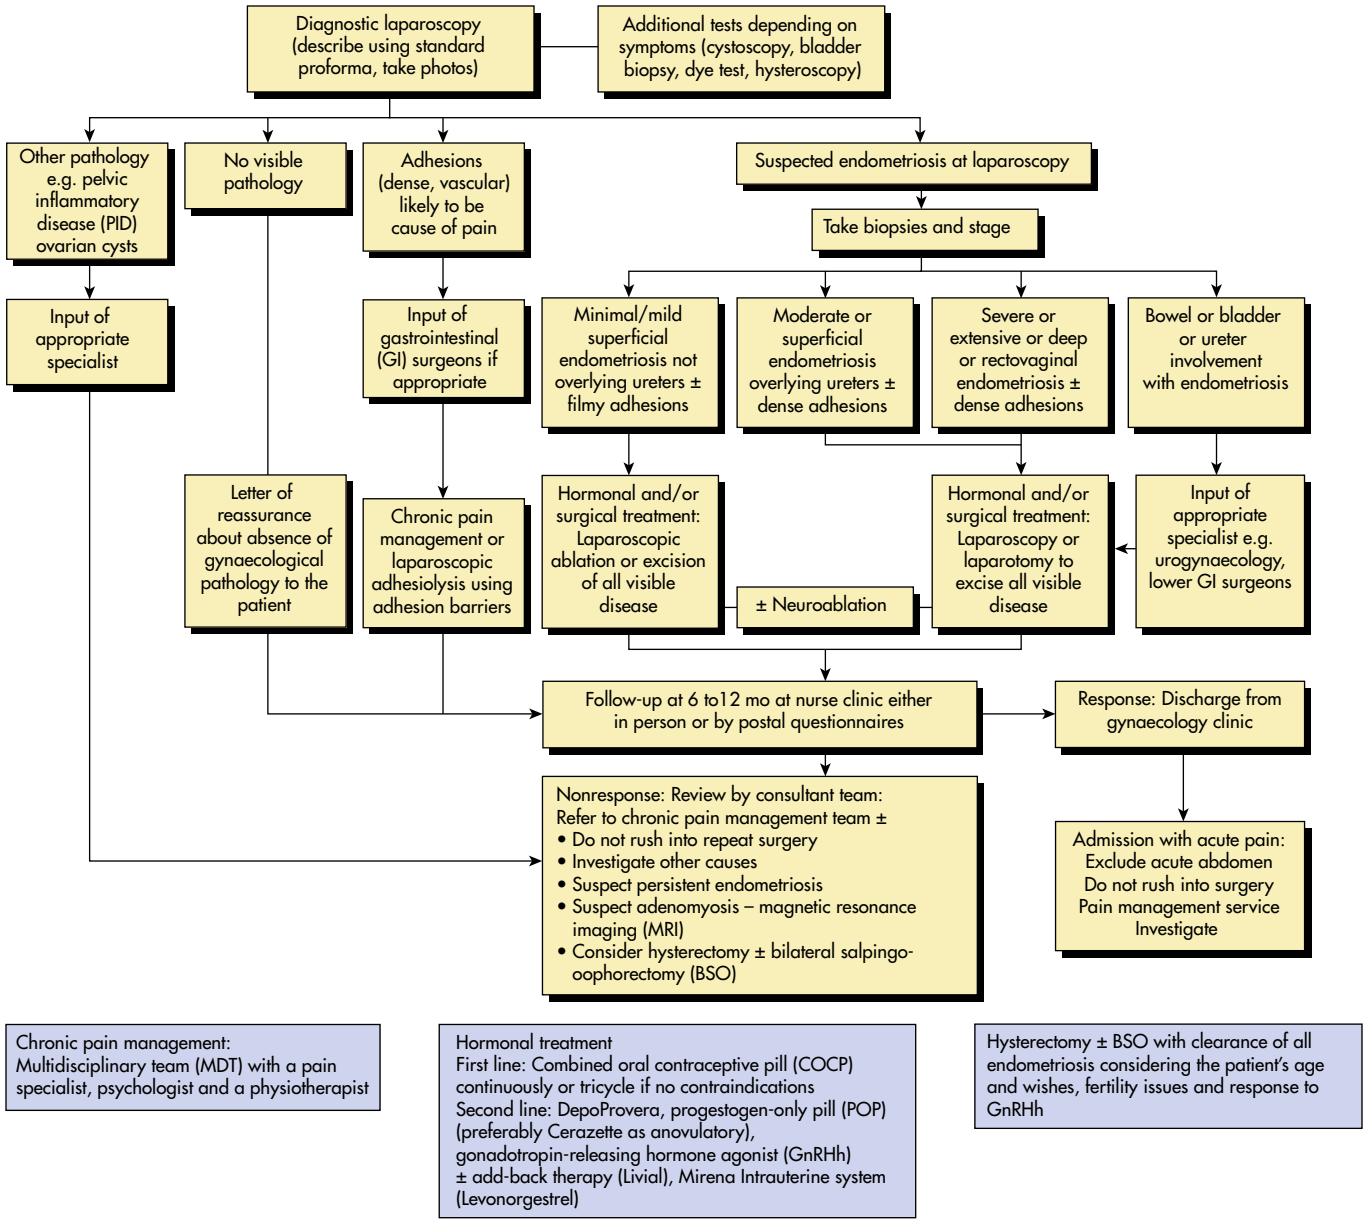

FIG. 1 An example of a management pathway for patients with endometriosis after laparoscopy.
(From Magowan BA: *Clinical obstetrics & gynecology,* ed 4, 2019, Elsevier.)

FIG. 2 Computed tomographic scan demonstrates adnexal masses of varying density, subsequently proven to be endometriomas. (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, WB Saunders.)

or in combination with conjugated estrogen 0.625 mg orally qd.
- Add-back therapy allows gonadotropin-releasing hormone (GnRH) agonist use to be extended to 1 yr based on limited studies available.

Alternative therapies for inhibition of estrogen action currently under investigation are:
- Aromatase inhibitors: Anastrozole, letrozole
- SERM: Raloxifene
- Agents enhancing cell-mediated immunity are cytokines (interleukin-12 and interferon-α2b)
- Immunomodulators (loxoribine, levamisole)
- Antiinflammatory: Pentoxifylline

SURGICAL MANAGEMENT:

Conservative:
- Directed at enhancing fertility or treating pain unresponsive to first-line medical treatment.
- Usually accomplished through laparoscopy.
- Removal or destruction of endometriotic implants by excision, electrocautery, or laser.
- Cystectomy for endometrioma; must remove cyst wall to be effective long-term.
- Laparoscopic uterosacral nerve ablation (LUNA) for midline pain such as dysmenorrhea or dyspareunia (evidence does not support its use).
- Unless pregnancy is desired, patient is usually started on GnRH agonist therapy or continuous OCP immediately after surgery.
- For those desiring pregnancy, surgery alone results in significant increase in fertility.

Definitive:
- Directed at relieving endometriosis-associated pain.
- Total abdominal hysterectomy with bilateral salpingo-oophorectomy and complete excision or ablation of endometriosis.
- Thorough abdominal exploration to ensure removal of all disease.
- Must be prepared to manage possible gastrointestinal and urinary tract endometriosis.
- 90% effective in pain relief; patient must be counseled that pain relief is not guaranteed.
- Estrogen replacement therapy (ERT) to be considered in all women undergoing definitive surgical management; after ERT, recurrence rate is 0% to 5% in women with endometriosis confined to the pelvis but 18% in women with bowel involvement.
- Concern for malignant degeneration exists in implants if unopposed estrogen is used after definitive surgical therapy.

MANAGEMENT OF ENDOMETRIOSIS-ASSOCIATED INFERTILITY:

Conservative surgery:
- Yields significantly higher pregnancy rate than does expectant management, in part because of correction of mechanical factors such as adhesions.

Assisted reproductive technologies:
- Can be used to circumvent unknown mechanism of endometriosis-associated infertility.
- Superovulation with clomiphene citrate or human menopausal gonadotropins; clomiphene citrate results in threefold pregnancy rate over expectant management.
- Further improvement with intrauterine insemination combined with superovulation.
- In vitro fertilization if above procedures are unsuccessful.

DISPOSITION

Tends to recur unless definitive surgery is performed, and should be considered a chronic condition.

REFERRAL

To a reproductive endocrinologist for advanced surgical management or infertility management

PEARLS & CONSIDERATIONS

COMMENTS

Patient information can be obtained through the following organizations: Endometriosis Association, 8585 North 76th Place, Milwaukee, WI 53223, 414-355-2200 or 800-992-ENDO; Women's Reproductive Health Network, P.O. Box 30167, Portland, OR 97230-9067 or 503-667-7757.

Endometritis

BASIC INFORMATION

DEFINITION

Endometritis is defined as inflammation of the endometrium and can occur postpartum or postabortal. Endometritis can also be unrelated to pregnancy (in an acute or chronic state); however, this chapter is primarily in reference to postpartum endometritis.

SYNONYMS

Endomyometritis
Endoparametritis
Metritis with pelvic cellulitis

ICD-10CM CODES

O85	Puerperal sepsis
O86	Other puerperal infections
O86.11	Cervicitis following delivery
O86.12	Endometritis following delivery
O86.13	Vaginitis following delivery
O86.19	Other infection of genital tract following delivery
O86.89	Other specified puerperal infections
N71.0	Acute inflammatory disease of uterus
N71.1	Chronic inflammatory disease of uterus

EPIDEMIOLOGY & DEMOGRAPHICS

- Overall rate of postpartum uterine infection: Estimated between 1% and 6%, as high as 13% when associated with chorioamnionitis
- Most common genital tract infection after delivery
- Usually presents early in postpartum period; more commonly seen after cesarean section or operative vaginal delivery than spontaneous vaginal delivery
- Additional risk factors include preterm delivery, prolonged labor, prolonged rupture of membranes, chorioamnionitis, multiple cervical examinations, and internal maternal or fetal monitoring

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Postpartum oral temperature >38° C (after first 24 hours)
- Symptoms of abdominal pain, fevers, chills, purulent or foul-smelling lochia, heavier vaginal bleeding
- On physical exam, tachycardia, localized uterine or parametrial tenderness, purulent or malodorous lochia; physical examination revealing uterine or parametrial tenderness

ETIOLOGY

Endometritis is usually polymicrobial including aerobic and anaerobic organisms: Group A or B streptococci, *Staphylococcus aureus* and *Bacteroides* species, *Neisseria gonorrhoeae, Chlamydia trachomatis,* enterococci, *Gardnerella vaginalis, Escherichia coli,* and *Mycoplasma.* Table E1 summarizes categories of endometritis and common pathogens.

TABLE E1 Endometritis

Category	Pathogen
Purpura sepsis	Staphylococcus, clostridia
Chronic (or acute and chronic) plasmacytic endometritis (CPE)	Chlamydia, gonorrhea, enteric organisms
Granulomatous endometritis	Tuberculosis, herpes simplex virus (HSV) infection, cytomegalovirus (CMV) infection, idiopathic
Xanthogranulomatous endometritis	Unknown
Lymphocytic endometritis	
Reactive endometritis	
Endometrial polyp	
Submucosal leiomyoma	
Intrauterine device (IUD)	
Ablation related	

From Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

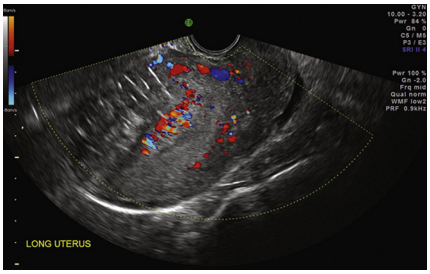

FIG. E1 Endometritis. Patient with uterine tenderness and fever 7 days after classic cesarean section for premature rupture of membranes, chorioamnionitis, and fundic presentation at 27 wks' gestational age. Sagittal transvaginal ultrasonography shows increased vascularity within the endometrium, which can be seen with endometritis. Linear echogenic foci within the anterior myometrium likely represent air and suture material in the vertical uterine incision. Patient's symptoms resolved with antibiotics. (From Fielding JR et al: *Gynecologic imaging*, Philadelphia, 2011, Saunders.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Chorioamnionitis (intrapartum intra-amniotic infection)
- Pelvic inflammatory disease
- Sepsis
- Urinary tract infection or pyelonephritis
- Wound infection or abscess
- Septic pelvic thrombophlebitis

WORKUP

Laboratory Tests:

- Complete blood count with differential
- If concerned for systemic infection, consider blood cultures or urine cultures
- Consider lactate if concerned for sepsis

IMAGING STUDIES

- Ultrasound (Fig. E1) may be useful if retained products are considered a possible source of infection.
- Consider CT imaging if concern for intraabdominal abscess.

Postpartum endometritis is overall a clinical diagnosis and based on documented fever (>38.0° C), with leukocytosis (WBC >15,000), abdominal pain, uterine tenderness, and purulent, malodorous vaginal discharge, with no other clear source of infection

TREATMENT

ACUTE GENERAL Rx

IV regimens:

- Clindamycin and gentamicin +/- ampicillin (considered "gold standard")
- Clindamycin and aztreonam
- Extended-spectrum penicillins: Piperacillin-tazobactam, ampicillin-sulbactam, ticarcillin-clavulanate
- Cephalosporins: Cefoxitin, cefotetan, cefotaxime
- Metronidazole, ampicillin, and gentamicin
- Carbapenems: Imipenem-cilastatin, meropenem, ertapenem
- Vancomycin: Consider adding to above regimens

Regimen should be continued for at least 24 to 48 hr after substantial clinical improvement. If response is not adequate (Table E2), broaden your differential and consider other sources of infection.

DISPOSITION

With appropriate antibiotic therapy, 95% to 98% cure rate. Patient can be discharged once 24 hours afebrile, and oral antibiotics are not typically indicated or recommended.

REFERRAL

For patients who do not respond within 48 to 72 hr of appropriate antibiotic therapy, obtain an infectious disease consultation or gynecologic consultation.

AUTHORS: **Siri M. Holton, MD,** and **Rachel Wright Heinle, MD, FACOG**

TABLE E2 Identified Causes of Poor Response to Antibiotic Therapy in Patients with Endometritis

Cause	Approximate Prevalence (%)
Infected mass, including abscess, hematoma, septic pelvic thrombophlebitis, pelvic cellulitis, retained placenta	40-50
Resistant organisms, commonly enterococci, in a patient receiving clindamycin-aminoglycoside or a cephalosporin	20
Additional cause, including catheter phlebitis, inadequate dose of antibiotics	10
No cause evident but response to empirical change in antibiotic therapy	20-30

From Gorbach SL: *Infectious diseases,* ed 2, Philadelphia, 1998, Saunders.

End-Stage Kidney Disease

BASIC INFORMATION

DEFINITION

End-stage kidney disease (ESKD) refers to chronic kidney disease (CKD) that is treated with renal replacement therapy (RRT), i.e., dialytic therapy or kidney transplantation.

SYNONYMS

End-stage renal disease
ESKD
Dialysis dependency
Renal replacement therapy
Chronic irreversible renal failure

ICD-10CM CODES

N18.6	End-stage renal disease
Z99.2	Dependence on renal dialysis
Z94.0	Kidney transplant status

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: According to the U.S. Renal Data System (USRDS), there were 124,675 incident cases of ESKD in the U.S. in 2016.

- 87.3% of incident individuals began RRT with hemodialysis (HD)
- 9.7% of incident individuals began RRT peritoneal dialysis (PD)
- 2.8% of incident individuals began RRT with a preemptive kidney transplant
- There has been an increase in incident PD cases more recently
- There is a significant cost difference among modalities, with average Medicare spending for HD at $90,971 per patient-yr versus PD at $76,177 per patient-yr

The incidence of ESKD differs among countries; the highest incidences are noted in Taiwan, the U.S., and the Jalisco region of Mexico.

PREVALENCE: According to the USRDS, there were 726,331 prevalent cases of ESKD in 2016. The number of prevalent cases has increased by approximately 20,000/yr.

- 63.1% of all prevalent ESKD patients in the U.S. were treated by HD.
- 7.0% of all prevalent ESKD patients were treated by PD.
- 29.6% of all prevalent ESKD patients had a functioning kidney transplant.

ESKD prevalence varies greatly by country, with Hong Kong, the Jalisco region of Mexico, and Guatemala having >50% PD utilization. Home HD use is highest in New Zealand and Australia.

PREDOMINANT SEX AND AGE: The incidence and prevalence of ESKD increases with age, but individuals can experience ESKD at any age. Older patients are more likely to be dialyzed with HD than PD. Males constitute 59% of prevalent ESKD patients.

GENETICS: Genome-wide association studies (GWAS) have shown several genes that are associated with the development of CKD and progression to ESKD. The *APOL1* gene is most strongly implicated. Single-nucleotide polymorphisms of the following genes are associated with greater risk for the development of ESKD: *UMOD, PRKAG2, ANXA9, DAB2,* and *SHROOM3.*

RISK FACTORS: Risk factors for the development of ESKD include proteinuria, higher body mass index, diabetes mellitus, high blood pressure, higher serum creatinine, male gender, lower educational status, and African American descent.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical presentations of uremia are myriad. Signs and symptoms may include hypertension, edema, uremic frost, asterixis, ankle clonus, altered mentation, pallor, and pericardial friction rub. Classic uremic symptoms include anorexia, dysgeusia, aversion to meat, nausea or vomiting, hiccups, pruritus, weight loss, reversal of sleep cycles, and loss of energy.

ETIOLOGY

The most common causes of ESKD in the U.S. are, in order of frequency, diabetes, hypertension, glomerulonephritis, and cystic diseases.

DIAGNOSIS

WORKUP

The diagnosis of ESKD is made in the setting of CKD, manifested by an elevated creatinine concentration and decrease of the glomerular filtration rate, typically <10 ml/min/1.73 m^2. Dialysis is initiated when uremia, volume overload refractory to diuretic therapy, or electrolyte abnormalities refractory to medical therapy is present. The workup of CKD is discussed elsewhere (see "Chronic Kidney Disease"). The ongoing workup of the consequences of ESKD include measures of anemia, iron metabolism, metabolic acidosis, and mineral and bone disease.

LABORATORY TESTS

Laboratory tests that warrant monitoring in ESKD include electrolytes, blood urea nitrogen, creatinine, glucose, calcium, phosphorus, intact parathyroid hormone, 25-hydroxyvitamin D, hemoglobin, ferritin, and transferrin saturation.

TREATMENT

- A patient with HD will require vascular access for dialysis, which may be a catheter, graft, or fistula (Table 1).
  1. A tunneled dialysis catheter is usually subcutaneously tunneled into the right internal jugular vein.
  2. An arteriovenous graft or fistula should be palpated regularly to ensure flow, which is noted by the presence of bruit and thrill. If the thrill is absent, this may indicate access thrombosis that is promptly addressed by percutaneous or surgical intervention.
  3. The most common arteriovenous fistulas are radiocephalic, brachiocephalic, and brachiobasilic. It is important in patients with CKD and ESKD to preserve veins in nondominant upper extremities by avoiding unnecessary venipunctures and intravenous lines, including central venous catheters and peripherally inserted central catheters.
- Patients who require dialysis have two primary options for RRT: HD and PD.
  1. In HD, the bloodstream is cannulated and diverted through a hemodialyzer that filters the plasma phase of blood running countercurrent to a dialysate.
     a. Dialysis kinetics are based primarily on diffusion down a concentration gradient, and the dialysate composition is produced such that solutes that are to be removed from the body (e.g., potassium) are in low concentration and solutes that are delivered during dialysis (e.g., bicarbonate) are at greater concentrations (Table 2).
     b. Dialysis is effective only for the clearance of non–protein-bound molecules.
     c. Blood flow rate varies from 300 to 400 ml/min. Dialysate flow rate ranges from 500 to 800 ml/min.
     d. Small solutes such as potassium will equilibrate quickly, whereas larger solutes such as beta 2-microglobulin take longer to equilibrate.
     e. Convective clearance also occurs because of solute drag, which accom-

TABLE 1 Hemodialysis Vascular Access

Vascular Access	Description	Benefits	Drawbacks
Tunneled catheter	Tunneled under skin to reduce communication from skin flora with blood	Immediate use	High infection risk High thrombosis risk
Arteriovenous graft	Tube made of biocompatible material attached end to side to artery and vein	Ready to use when swelling resolves (~2 wk) Able to use in most patients	High stenosis/thrombosis rate Moderate infectious risk
Arteriovenous fistula	Vein cross-cut attached end to side to artery High-pressure flow dilates and thickens vein	Lowest infectious risk Longest lasting with least thromboses	Maturation time Primary patency

TABLE 2 Composition of Typical Hemodialysis and Peritoneal Dialysis Solutions

Component	Concentration in Hemodialysis Solutions	Concentration in Peritoneal Dialysis Solutions
Sodium	135-145 mEq/L	132 mEq/L
Potassium	1-3 mEq/L	0 mEq/L
Calcium	2.5-3.5 mEq/L	2.5-3.5 mEq/L
Chloride	95-110 mEq/L	95-105 mEq/L
Magnesium	0.5-1 mEq/L	0.5 mEq/L
Bicarbonate	32-40 mEq/L	
Lactate		35-40 mEq/L
Acetate	2.5-5 mEq/L	
Glucose	200 mg/dl	1500-4250 mg/dl

panies ultrafiltration, the method of fluid removal.

2. In PD, the blood flow originates from the richly vascular parietal and visceral peritoneum, and the semipermeable membrane is the peritoneal membrane.
   a. A tunnelled catheter is placed to be able to infuse and drain dialysate directly into the peritoneum, and solute transfer occurs via convection or diffusion across concentration gradients.
   b. PD can be performed manually throughout the day or overnight via an automated cycler device.
   c. Peritoneal dialysate is dextrose based and hypertonic. The hypertonicity produces ultrafiltration, and the concentration of dextrose is used to create a hypertonic dialysate that ultrafilters plasma fluid across the peritoneal membrane.

- In patients who are indicated for RRT, withholding dialysis is not without risk.
  1. Patient with hyperkalemia are at risk for sudden cardiac death from hyperkalemia, and patients with metabolic acidosis are at risk for cardiovascular compromise, bone demineralization, and other electrolyte and mineral disturbances.
  2. Patients with untreated uremia are at risk for confusion, altered mentation, and coma.
  3. Uremia may cause platelet dysfunction and increased risk for bleeding.
  4. Patients with late-stage CKD are typically hypertensive. If hypertension is untreated, the risks for accelerated heart disease and/or stroke increase.
- In addition to the provision of dialysis, the management of the patient with ESKD also involves close attention to other related conditions, including anemia, mineral and bone disease, and cardiovascular disease.
  1. Patients receiving dialysis experience anemia for several reasons, including erythropoietin deficiency, gastrointestinal bleeding, functional and absolute iron deficiency, increased red blood cell fragility, and blood loss from HD.
     a. Management of anemia in CKD depends on the primary causative factor.
     b. Iron utilization is estimated using ferritin (>100 ng/ml) and transferrin saturation (>20%). Patients who do not meet these parameters are managed with intravenous iron or a trial of oral iron. Intravenous iron may be administered without a trial of oral iron. In patients who are iron repleted, erythropoiesis-stimulating agents are used to increase hemoglobin. Large randomized controlled trials demonstrate an association between increased cancer death and stroke with attainment of hemoglobin levels >11g/dl. The target hemoglobin range for a dialysis patient is 9 to 11 g/dl.
- Patients with ESKD are at risk for several different metabolic bone diseases.
  1. Secondary hyperparathyroidism of renal origin, which is aggravated by metabolic acidosis. The intact PTH level is characteristically elevated in these individuals (>600 pg/ml).
  2. Adynamic bone disease, which occurs more frequently in individuals with diabetes. Typically, the intact PTH level is low (<150 pg/ml) in these patients who typically have diabetes.
  3. Mixed uremic osteodystrophy, which has characteristics of hyperdynamic and adynamic bone remodeling.
  4. Osteopenia.
  5. The gold standard diagnosis for establishing a histologic diagnosis is via bone biopsy. Bone lesion parameters are reported as turnover, mineralization, and volume.
  6. Patients who do not undergo bone biopsy are managed by serologic markers, calcium, phosphate, and intact parathyroid hormone.
  7. PD has a higher risk for adynamic bone disease, whereas patients receiving HD are at greatest risk for osteitis fibrosis cystica and mixed lesions.
- Patients with ESKD are considered to have a coronary heart disease equivalent and are at increased risk for mortality from cardiovascular causes. However, data are lacking regarding the efficacy of cardiovascular risk modification.
  1. Studies of statin therapy in patients with ESKD have not shown a reduction in cardiovascular mortality.
  2. Levels of cardiac biomarkers such as troponin-I and N-terminal pro-B-type natriuretic peptide (NT-proBNP) can be chronically elevated in patients with ESKD. Interpretation of these biomarkers must be considered in the context of clinical findings.
  3. Hemoglobin A1c levels are not equivalent to comparable levels in non-CKD patients. The levels of patients with ESKD should be considered greater by ~0.3% than reported.
- Because multiple medications are renally excreted or nephrotoxic, careful attention must be paid to dosing and choice of medications. Commonly used medications that should be used with caution in patients with ESKD include low-molecular-weight heparin, morphine, oxycodone, gabapentin, pregabalin, digoxin, bisphosphonates, metformin, and electrolyte-containing solutions, including milk of magnesium, magnesium citrate, aluminum hydroxide, and magnesium hydroxide.

DISPOSITION

Morbidity and mortality remain exceptionally high for patients who require RRT.

- Dialysis patients in 2016 had a mortality rate of 164 deaths per 1,000 patient-yr.
- This rate has been improving, with net reductions in mortality from 2001 to 2016 of 28% for HD patients and 43% for PD patients.
- HD patients have greater earlier mortality, and PD patients have greater delayed mortality.
- 5-yr survival probability rates are 42% for HD patients and 52.1% for PD patients. It is likely that this discrepancy is related to patient selection factors, not inherent differences within modalities.

Enteropathic Arthritis

BASIC INFORMATION

DEFINITION

Enteropathic arthritis (EA) is an inflammatory joint disease associated with inflammatory bowel diseases (IBD) such as Crohn disease (CD), ulcerative colitis (UC), and microscopic colitis. Less frequently, EA is associated with other gastrointestinal disorders, including Whipple disease, celiac disease, and bowel-associated dermatitis-arthritis syndrome related to bypass surgery or intestinal disease. EA is included in the family of spondyloarthropathies (SpA), which have features of peripheral inflammatory arthritis, axial spondylitis and sacroiliitis, enthesitis, dactylitis, uveitis, and rashes. Arthritis is the most common extraintestinal manifestation of IBD.

SYNONYMS

IBD-related spondyloarthropathy
Enteroarthritis
Arthritis associated with gastrointestinal disease

M07.69	Enteropathic arthropathies, multiple sites

EPIDEMIOLOGY & DEMOGRAPHICS

Peripheral arthritis occurs in 5% to 15% of patients with IBD in most studies and is slightly more common in CD than in UC. Spinal involvement occurs in 10% to 20% of cases and may be the only articular manifestation or be accompanied by peripheral arthritis.

PREDOMINANT SEX AND AGE: Males and females equally affected. Inflammatory back pain usually presents before the age of 45 yr. Onset of peripheral arthritis is usually between 25 and 45 yr of age.

RISK FACTORS:

- Active large bowel disease
- Family history of IBD
- Cigarette smoking
- Genetics
- Complicating intestinal manifestations such as abscesses and perianal disease

GENETICS: The presence of *HLA-B27* is the strongest association with SpA. Recent genome-wide association studies demonstrated a genetic overlap between IBD and SpA, implicating *NOD2 (CARD15)* and interleukin 23 receptor *(IL23R)* as susceptibility genes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Two types of joint involvement in IBD: Peripheral and/or axial. Peripheral: Affects peripheral joints, predominantly lower limb joints. Axial: Affects the spine in the form of sacroiliitis with or without spondylitis; can be similar to ankylosing spondylitis or other idiopathic SpA (e.g., psoriatic arthritis, reactive arthritis, undifferentiated SpA).
- Axial involvement is found more commonly in CD than in UC. Axial disease is independent of IBD activity. Can have asymptomatic sacroiliitis.
- Peripheral arthritis is the most frequent extra intestinal finding in both CD and UC. Peripheral and spinal disease equally affects both sexes (Table 1).
- Type 1 peripheral arthropathy (pauciarticular, fewer than five joints): Usually acute and self-limited asymmetric inflammatory arthritis; commonly affects large joints of legs such as the knee; occurs early in the course of IBD and commonly parallels the disease activity or flares of IBD, generally self-limiting.
- Type 2 peripheral arthropathy (polyarticular, five or more joints): Affects mainly the metacarpophalangeal, proximal interphalangeal, knee and ankle joints; bilateral and symmetric; may be migratory, nonerosive. Symptoms may take a more chronic course, independent of IBD activity.
- Main complaints are inflammatory back pain, buttock pain, joint pain, and swelling (with prolonged morning stiffness and fatigue); symptoms worse with rest or inactivity and improve with exercise.
- Examination reveals evidence of synovitis, progressive limitation of spinal mobility.
- Periarticular and other extraintestinal manifestations include enthesitis (inflammation of tendon insertion sites into bone such as Achilles or plantar fascia), dactylitis (flexor tenosynovitis of a finger or toe causing sausage like swelling of digit), uveitis, and psoriasis.
- Uveitis in IBD is more often bilateral and more prone to chronicity.
- Erythema nodosum, pyoderma gangrenosum can be associated with skin lesions in IBD.

ETIOLOGY

In genetically predisposed individuals with intestinal disease, the co-occurrence of joint inflammation provides important support to the theory that dysbiosis in the gut microbiome can link colitis to the development of EA.

TABLE 1 Enteropathic Arthritis

Feature	Peripheral Arthritis	Sacroiliitis, Spondylitis
Crohn Disease		
Frequency in CD	10%-20%	2%-7%
HLA-B27 associated	No	Yes
Pattern	Transient, symmetrical	Chronic
Course	Related to activity of CD	Unrelated to activity of CD
Effect of surgery	Remission of arthritis uncommon	No effect
Effect of anti-TNF therapy	Effective	Effective
Ulcerative Colitis		
Frequency in UC	5%-10%	2%-7%
HLA-B27 associated	No	Yes
Pattern	Transient	Chronic
Course	More common in pancolitis than proctitis; related to activity of UC	Unrelated
Effect of surgery	Remission of arthritis	No effect

CD, Crohn disease; *HLA,* human leukocyte antigen; *TNF,* tumor necrosis factor; *UC,* ulcerative colitis.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypertrophic osteoarthropathy
- Osteonecrosis (avascular necrosis)
- Septic arthritis
- Other idiopathic seronegative spondyloarthropathies (e.g., reactive arthritis, psoriatic arthritis, ankylosing spondylitis)
- Behçet syndrome
- Rheumatoid arthritis

WORKUP

Diagnosis mainly relies on clinical features and imaging data. There is no gold standard for diagnosis.

LABORATORY TESTS

- Laboratory testing: Markers of inflammation such as sedimentation rate and C-reactive protein (CRP) may reflect underlying disease activity of bowel disease and thus may not be useful to track for EA activity. CBC can reveal leukocytosis, anemia, thrombocytosis suggestive of inflammatory response.
- Synovial fluid is nonspecific; shows mild to marked inflammation: WBC 1500 to 50,000/mm^3.
- Serologic tests for rheumatoid arthritis are negative (rheumatoid factor, cyclic-citrullinated peptide antibodies), and lupus-related antinuclear antibodies are absent.
- Tests for other intestinal diseases based on clinical suspicion: Whipple diagnosis is based on histology with Periodic acid–Schiff (PAS)-positive cells, serology for *T. whipplei*, and culture; celiac disease immunoglobulin A (IgA) antitissue transglutaminase and anti-endomysial antibodies along with diagnostic villous atrophy on small bowel biopsy; microscopic colitis diagnosed only through histology from colonoscopy showing collagenous colitis or lymphocytic colitis.
- Calprotectin measured in the serum or in the stools has been used to identify subclinical bowel inflammation in patients with SpA. Individuals who had both CRP and calprotectin elevated had an increased frequency of bowel inflammation compared to patients who had low levels of these proteins.

IMAGING STUDIES

- Plain x-ray of the spine and pelvis may appear normal in early disease but with progression may show evidence of sacroiliitis, spondylitis, ankyloses.
- X-ray of peripheral joints may show soft tissue swelling, periostitis, or joint effusion.
- MRI may be used to assess early changes of spondyloarthritis when plain x-rays are negative. MRI is the most sensitive method of detecting sacroiliitis in IBD patients.
- Musculoskeletal ultrasonography is a noninvasive, safe, and easily reproducible means of detecting early pathologic changes in SpA patients. It can identify characteristic features of enthesitis, bone erosions, synovitis, bursitis, and tenosynovitis.

Rx TREATMENT

- Effective treatment of underlying IBD is helpful in controlling the peripheral arthritis. The goal of treatment of EA is reducing inflammation to relieve suffering and prevent joint deformity and disability.
- When IBD and SpA coexist, treatment strategy should also address extraintestinal and extraarticular features such as enthesitis, dactylitis, uveitis, and psoriasis, with need for tailored consideration of certain limited biologic options.
- Avoidance of NSAIDs due to controversial increased risk of exacerbation of intestinal disease.

NONPHARMACOLOGIC THERAPY

Rest, physical therapy, and exercise such as swimming

ACUTE GENERAL Rx

- There has been concern that NSAIDs exacerbate IBD and that NSAID-related adverse events such as ulcers and GI bleeding may mimic IBD flares. COX-2 inhibitors may be preferred to traditional NSAIDs, but similar concerns and cautions apply.
- Intraarticular steroid injections may help treat joint synovitis.
- Systemic steroids can help reduce polyarticular joint and IBD activity but should be used at the lowest effective dose and ideally for only short courses.

CHRONIC Rx

- Immunomodulatory agents such as sulfasalazine, azathioprine, 6-mercaptopurine, methotrexate, and cyclosporine can be used to treat active IBD, peripheral arthritis, and associated skin conditions. Peripheral joint disease responds better to these agents than axial disease. Tumor necrosis factor (TNF) inhibitors, particularly infliximab, adalimumab, and certolizumab, are useful to treat both arthritis (axial or peripheral) and severe, refractory IBD. Golimumab is also in use for refractory IBD and is used for arthritis. Etanercept is not effective to control IBD.
- The axial disease associated with IBD is treated similar to other SpA. Medications approved for other SpAs, such as ustekinumab (anti-IL12/23), secukinumab (anti-IL17A), ixekizumab (anti-IL17), and Janus kinase (JAK) inhibitors, may be effective therapies for EA, although their effectiveness for IBD is not clear. Anti-IL17 is usually avoided with IBD, given possible worsening of IBD.
- The choice of biologic requires the consideration of extraarticular and extraintestinal features such as skin disease or uveitis. The latter can be treated with infliximab or adalimumab, both of which also treat the IBD.
- For highly active IBD, particularly UC, colectomy has been found to ameliorate peripheral joint inflammatory disease but does not influence axial involvement.
- Interdisciplinary approach and active cooperation between rheumatologist and gastroenterologist through combined clinics, for example, are essential.

REFERRAL

Rheumatology and gastroenterology

PEARLS & CONSIDERATIONS

- When a single joint is affected, consider joint aspiration to rule out septic arthritis. Signs of infection may be atypical in those receiving anti-inflammatory or immunosuppressive medications.
- Other extraintestinal manifestations of enteropathic arthritis include skin and mucous membrane involvement, anterior uveitis, Hashimoto thyroiditis, genitourinary involvement (nephrolithiasis), aortic insufficiency, and cardiac conduction abnormalities. These are often seen in patients with prolonged disease activity and positive *HLA-B27*.

BASIC INFORMATION

DEFINITION

Enuresis refers to the voiding of urine into clothes or in bed that is either voluntary or involuntary in individuals who are expected to be continent (>5 yr of age). The diagnosis is made if voiding occurs at least twice a wk for 3 mo. Primary enuresis refers to enuresis without a period of continence, whereas secondary enuresis occurs after a 6-mo period of normal bladder control.

SYNONYMS

Urinary incontinence
Bedwetting
Nocturia

ICD-10CM CODES

N39.44	Nocturnal enuresis
F98.0	Enuresis not due to a substance or known physiological condition

DSM-5 CODES

307.6

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Ages 5 to 10 yr. 5 to 7 million children in the U.S. have enuresis.

PREVALENCE (IN U.S.):

- Age 5 yr: 7% of males and 3% of females
- Age 10 yr: 3% of males and 2% of females
- Ages 15 and older: 1% of males and females

PREDOMINANT SEX: Twice as many males as females at all ages

PREDOMINANT AGE: Highest prevalence at age 5 with a steady decrease thereafter at a rate of approximately 12% to 15% per yr

GENETICS:

- Approximately 75% of children with enuresis have a first-degree relative with enuresis.
- Almost twice as common in monozygotic than dizygotic twins.

RISK FACTORS:

- Developmental delays
- Behavior problems and attention deficit hyperactivity disorder (ADHD)
- Younger age
- Male
- Positive family history

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Three enuresis subtypes are defined in DSM-5:

1. Nocturnal only (also known as monosymptomatic enuresis): Occurs in each sleep stage in proportion to the time spent in the particular stage. May occur during transition from deep sleep to rapid eye movement (REM) and is without other lower urinary tract symptoms.
2. Diurnal only (also referred to as nonmonosymptomatic or urinary incontinence): More frequent in girls and rarely after age 9 yr; voiding occurs in early afternoon on school days. Within this subtype, individuals have "urge incontinence" with sudden symptoms of urgency and detrusor instability or "voiding postponement" where individuals ignore urges until the point of incontinence.
3. Combined nocturnal and diurnal.

ETIOLOGY

- Enuresis often correlates with other maturational delays, particularly language, motor skills, and social development.
- May be related to toilet training issues, stress (secondary enuresis), inability to concentrate urine, altered smooth muscle physiology, small bladder capacity, or dysfunction of the arousal system.
- Diurnal enuresis associated with a higher rate of urinary tract infections.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The pathophysiology of primary enuresis involves the inability to awaken from sleep in response to full bladder, or a decreased functional capacity of the bladder with possible excessive nighttime urine production.
- May be associated with encopresis and sleep disorders such as sleep terrors; much less likely to be a primary psychological disorder.
- Organic causes of enuresis include diabetes mellitus, diabetes insipidus, bladder outlet obstruction, small bladder capacity, detrusor instability, urethral valves, meatal stenosis, cerebral palsy, spina bifida, pelvic mass, impacted stool, sedating medications, nocturnal seizures, urinary tract infections, kidney disease, hyperthyroidism, pinworms, and obstructive sleep apnea.

WORKUP

- History and physical examination to rule out anatomic abnormalities, look for signs of obstructive sleep apnea. Fluid intake, voiding diaries, and stooling histories may be useful. Family history of enuresis, particularly for nocturnal enuresis.
- Children frequently experience shame, so gentleness and care must be exercised when questioning or examining the child.
- Observation of voiding is useful to assess for weak stream.

LABORATORY TESTS

- Urinalysis with specific gravity and urine culture if white cells or nitrites to rule out infection
- Serum studies to rule out diabetes, electrolyte abnormalities, or renal dysfunction

IMAGING STUDIES

- In complicated cases, or if there is evidence of obstructive sleep apnea, sleep studies may be useful.
- If an anatomic abnormality is suspected, urologic imaging, including voiding cystourethrogram and renal sonogram is possibly indicated: An abdominal x-ray may demonstrate stool retention; MRI of the spine if evidence of abnormalities of lower spine or perineum is found on examination.

TREATMENT

NONPHARMACOLOGIC THERAPY

Behavioral treatment:

- Scheduled voiding to reduce the frequency of enuretic episodes.
- Motivational therapy including sticker or star charts to reward child for dry nights.
- Alarm and pad technique: 66% response rate (compared with 4% of control participants), although about half relapse.
- Punishment for enuresis is not effective.

ACUTE GENERAL Rx

Education and motivational therapy

CHRONIC Rx

- Alarm pad is first-line treatment.
- Desmopressin (DDAVP) administered orally at bedtime significantly reduces the incidence of bedwetting with complete response in 30% of patients and another 40% with dramatic reduction in symptoms. Relapse rate is as high as 70% after discontinuation. Of note, the intranasal preparation is associated with a greater risk for water intoxication and is not recommended.
- Tricyclic antidepressants (imipramine): Efficacy supported by randomized control trials. Use with care in children, given the side effect profile.
- Serotonin reuptake inhibitors: Lack of adequate trials is notable.
- Indomethacin suppositories may reduce normal prostaglandin inhibitory effects on antidiuretic hormone.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Weak or limited evidence for complementary treatment interventions, including psychotherapy, hypnosis, chiropractic care, acupuncture, and medicinal herbs

DISPOSITION

- After age 5 yr, the rate of spontaneous remissions is approximately 12% to 15% per yr.
- The disorder usually resolves by adolescence. However, effective treatment spares considerable misery.
- Fewer than 1% will have enuresis as adults.

REFERRAL

- If coexisting, a psychiatric condition complicates the course of treatment.
- Referral to a pediatric urologist is indicated for primary enuresis refractory to therapy and for selected secondary causes (e.g., urinary tract malformations, neurologic disorders).

PEARLS & CONSIDERATIONS

Illness, hospitalization, and family stressors may precipitate recurrent enuresis after a period of dryness.

Eosinophilic Esophagitis (EoE) PTG

BASIC INFORMATION

DEFINITION

Eosinophilic esophagitis is a chronic, antigen- and immune-mediated disease, which requires these inclusion criteria after secondary causes of esophageal eosinophilia are excluded:

1. Inflammation secondary to eosinophilic infiltration within the esophagus (confirmed with at least 15 eosinophils per high power field (HPF) detected on biopsy of mucosa taken at mid and distal esophagus)
2. Symptoms related to esophageal dysfunction Mucosal eosinophilia is isolated to the esophagus and persists after a proton pump inhibitor (PPI) trial

SYNONYMS

Esophageal eosinophilia
EoE
EE

ICD-10CM CODE
K20.0 Eosinophilic esophagitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): One to 20 new cases per 100,000 inhabitants per yr, increased from last year
PREVALENCE: Between 13 and 49 cases per 100,000 inhabitants
PREDOMINANT SEX: Male predominance (ratio ~3:1)
PREDOMINANT AGE: Peak of disease activity at age 35 to 39
PEAK INCIDENCE: Older children; in adults, ages 30 to 50
GENETICS:

- Association between thymic stromal lymphopoietin *(TSL)* gene mutation and risk for EoE
- Higher risk in those with homozygous pattern for the mutation
- *TSL* gene found on Yp11.3 chromosome
- Association with polymorphism on eotaxin-3 (CCL-26)

RISK FACTORS/ETIOLOGY: Genetic, host immune, and environmental

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Adults: Dysphagia to solid foods, food impaction, heartburn, noncardiac chest pain, increased time to consume meals, concurrent allergic disease (asthma, eczema, rhinitis, atopic dermatitis, seasonal/food allergies)
- Children: Vomiting, regurgitation, nausea, epigastric/abdominal pain, chest pain, water brash, globus, decreased appetite, gagging, choking, refusal of food, possible atopy
- Often associated with asthma, rhinitis, dermatitis, and other atopic conditions

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gastroesophageal reflux disease
- PPI-responsive esophageal eosinophilia (PPI-REE)—see "Acute General Rx"
- Celiac disease
- Eosinophilic gastroenteritis
- Crohn disease
- Hypereosinophilic syndrome
- Achalasia
- Vasculitis/pemphigus/connective tissue diseases
- Infectious (fungal/viral)
- Graft-versus-host disease
- Pemphigus
- Connective tissue disease

WORKUP

- Esophagogastroduodenoscopy (EGD) with at least two to four biopsies from distal and mid/proximal esophagus after a PPI trial
- Confirmation: Persistence of symptoms *and* ≥15 eosinophils/HPF on pathology (Fig. 1) although esophagus is normal in ~5% to 10% of patients
- Other histological findings can include basal zone hyperplasia, dilated intracellular spaces, and subepithelial fibrosis
- Endoscopic findings can include white mucosal papules, which represent eosinophilic microabscesses, linear furrows, esophageal narrowing with stricture, mucosal tearing, and esophageal trachealization (Fig. 2), esophageal rings, felinization of esophagus. Felinization of the esophagus is a radiologic term used to describe 1 to 2 mm transverse folds found circumferentially along the entire lumen of the esophagus that appear transiently on EGD and barium studies, possibly attributed to thickened and contracted muscularis mucosae

LABORATORY TESTS

- Forty percent to 50% have elevated peripheral eosinophilia
- Fifty percent to 60% have elevated serum immunoglobulin E (IgE) levels

IMAGING STUDIES

Esophagram can reveal rings and strictures.

TREATMENT

NONPHARMACOLOGIC THERAPY

Three strategies of dietary therapy:

- Empiric six-food elimination diet (eliminates milk, soy, egg, wheat, nuts, and seafood) For patients with response, foods can be reintroduced one at a time for 6 wk
- Total elimination of all food allergens with elemental or amino acid–based formula

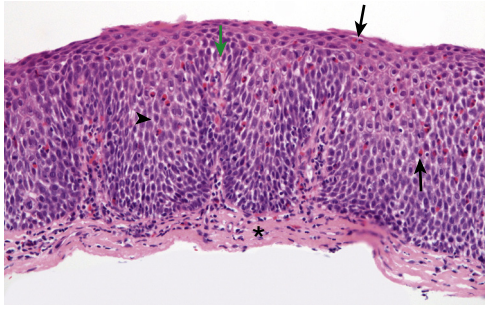

FIG. 1 H&E staining of an esophageal specimen from a patient with eosinophilic esophagitis. *Arrows* point to eosinophils, including some at the surface. *Arrowhead* points to dilated intercellular spaces. *Asterisk* marks the lamina propria, showing inflammation and fibrosis. *Green arrow* points to elongated papillae. There is also marked basal layer hyperplasia, with the basal layer reaching almost to the luminal surface. *H&E*, hematoxylin and eosin. (From Feldman M et al *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

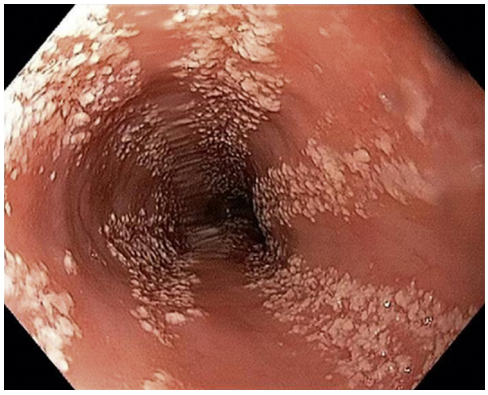

FIG. 2 Endoscopic view of eosinophilic esophagitis with furrowing and exudates. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

- Targeted elimination diet guided by allergy testing, typically skin prick testing or patch testing
- Dilation if stricture is present and/or patient is refractory to therapy with the goal of creating a tear in the mucosa

ACUTE GENERAL Rx

- An 8-wk trial of PPI therapy to exclude PPI-responsive esophageal eosinophilia should be initiated after an initial EGD with biopsy based on clinical symptoms with subsequent EGD (with biopsies).
  1. If eosinophilia persists on biopsy despite PPI use, diagnosis is EoE
  2. If eosinophilia is reduced on repeat biopsies, patient is considered to have proton pump inhibitor-responsive esophageal eosinophilia (PPI-REE), not EoE
- An EGD (with biopsies) should be performed initially if a critical stricture is present (e.g., patient presents with food impaction).
- If EoE is confirmed, patient should be tried on aerosolized topical glucocorticoids (fluticasone or budesonide) and/or dietary elimination.
  1. Topical steroids shown to be most effective:
     a. Swallowed fluticasone 880 to 1760 mcg/day in a divided dose bid (adult dosing)
        (1) Delivered by meter-dosed inhaler without a spacer.
        (2) Medication is sprayed into the patient's mouth and then swallowed.
        (3) Patient should **not** inhale when the medication is being delivered.
        (4) Patient should not eat or drink for 30 to 60 min following administration.
     b. Swallowed budesonide 2 mg daily, typically in divided doses
        (1) Administered using a nebulizer: Patient then instructed to swallow accumulated liquid
        (2) Administered as viscous slurry: Mixing 1 mg/2 ml nebulizer ampules with sucralose (5 1-g packets per 1 mg of budesonide)
        (3) Patient should not eat or drink for 30 to 60 min after taking the budesonide suspension

CHRONIC Rx

- If patient is responsive to PPI therapy, EoE has been excluded and patient can be continued on PPI therapy with surveillance of symptoms.
- If patient is responsive to aerosolized topical steroids and/or dietary modification, continue steroids at lowest dose and/or continue dietary elimination.
- If lack of response to initial therapy:
  1. Assess compliance.
  2. Restrict diet further.
  3. Increase steroid dose or consider alternative steroid.
  4. Switch from dietary modification to steroid therapy and vice versa.
  5. Consider second-line agents or clinical trials.
  6. Reevaluate diagnosis and secondary causes of esophageal eosinophilia (see "Differential Diagnosis" earlier).
- Chronic histologic and symptomatic surveillance is recommended.
- If dysphagia persists, endoscopic dilation is recommended for amelioration of symptoms.

DISPOSITION

Follow-up by gastroenterologist is important to gauge progression or regression of disease.

REFERRAL

Referrals to gastroenterologists, allergists, and dieticians allow for a multidisciplinary approach to diagnosis and management of EoE.

PEARLS & CONSIDERATIONS

COMMENTS

- EoE can be confused with PPI-REE, and patients should undergo a PPI trial before confirmation of EoE and utilization of topical steroids, step-up elimination diet, or esophageal dilation.
- Endoscopic surveillance of disease with or without symptoms is important.
- While esophageal dilation is the mainstay of therapy in patients with esophageal strictures, narrowing of esophagus, and esophageal rings, dilation will not reduce the risk of recurrence as eosinophilic burden is unaffected.

Eosinophilic Fasciitis

BASIC INFORMATION

DEFINITION

Eosinophilic fasciitis (EF) is a rare inflammatory disease of the skin and subcutaneous tissue characterized by erythema, edema, and eosinophilia in peripheral blood that was first described by Lawrence Shulman in 1974. This condition starts with acute onset of symmetrical erythema, edema, and induration of the trunk or an extremity and later may progress to sclerosis of the dermis and subcutaneous fascia leading to contractures.

SYNONYMS

Shulman syndrome
Diffuse fasciitis with eosinophilia

ICD-10CM CODE
M35.4 Diffuse (eosinophilic) fasciitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Exact incidence of EF is unknown.
- Women are 1.3 to 2.1 times as likely as men to be affected.
- Mean age of onset: 47 to 57 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Early stage:
  1. Acute onset of limb (typically symmetrical) or trunk erythema and edema
  2. Peripheral eosinophilia
- Late stage:
  1. Indurated collagenous thickening of the subcutaneous fascia
  2. Peripheral eosinophilia often absent
- Cutaneous: Peau d'orange, Groove sign (visible indentation of superficial vein; Fig. E1)
  1. Face, hands, and feet are typically spared
- Musculoskeletal: Limited joint mobility (joint contractures in 50% to 60% of patients)
- Neuropathies: Cranial and peripheral neuropathies (carpal tunnel syndrome, mononeuritis multiplex)
- Constitutional: Myalgia, muscle weakness, fatigue, weight loss
- Hematologic: Up to 10% of EF cases have been associated with hematologic disorders such as aplastic anemia, myeloproliferative disorders, lymphoma, leukemia, and multiple myeloma
- Patients with EF often lack visceral involvement or history of Raynaud phenomenon

ETIOLOGY

The etiology is unknown. A proposed mechanism of disease is a nonspecific immune-mediated inflammation of the fascia triggered by stress (exercise, trauma), exposures (medications, radiation therapy, burns), infection (*Borrelia burgdorferi*), autoimmune disease, or hematologic disorder. Most cases are considered idiopathic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Localized scleroderma: Morphea, linear
- Systemic scleroderma
- Scleroderma-like disorders: Nephrogenic systemic fibrosis, scleromyxedema, scleredema
- Hypereosinophilic syndrome
- Deep vein thrombosis
- Cellulitis
- Graft-versus-host disease

WORKUP

- Diagnosis by histopathology with fascial thickening and fibrosis is considered gold standard.
- Universally accepted, validated diagnostic criteria are lacking.
- Proposed diagnostic criteria (two major or one major and two minor) by Pinal-Fernandez et al (2014):
  1. Major:
     a. Swelling, induration, and thickening of the skin and subcutaneous tissue that is symmetrical or nonsymmetrical, diffuse (extremities, trunk, and abdomen), or localized (extremities)
     b. Fascial thickening with accumulation of lymphocytes and macrophages with or without eosinophilic infiltration (determined by full-thickness wedge biopsy of clinically affected skin)
  2. Minor:
     a. Eosinophilia $>0.5 \times 10^9$/L
     b. Hypergammaglobulinemia >1.5 g/L
     c. Muscle weakness and/or elevated aldolase levels
     d. Groove sign and/or peau d'orange
     e. Hyperintense fascia on MR T2-weighted images
- Exclusion criteria: Diagnosis of systemic sclerosis

LABORATORY TESTS

- Peripheral eosinophilia in 64% to 86% of cases in early stage
- Elevated erythrocyte sedimentation rate and/or elevated aldolase usually correlates with disease activity
- Creatinine kinase usually normal
- Hypergammaglobulinemia (35%) of unclear significance

IMAGING STUDIES

- Consider MRI during initial work-up:
  1. Noninvasive
  2. Identifies presence of fascia edema and inflammation
  3. Can guide appropriate site for biopsy or be used if biopsy nondiagnostic
- Consider PET-CT (though limited data based on case reports)

TREATMENT

ACUTE GENERAL Rx

- Given the rarity of EF, no randomized controlled trials have been performed to date.
- Corticosteroids (prednisone 0.5 to 1 mg/kg/d) are considered mainstay of treatment.
- Based on a recent retrospective review from 2016 of the largest cohort of EF patients to date, complete response is more likely with combination of corticosteroids and methotrexate compared to other treatment combinations, corticosteroid therapy, or treatment without corticosteroids.
- Other potential agents based on case reports include mycophenolate mofetil (MMF), intravenous immunoglobulin (IVIG), cyclosporine, azathioprine, infliximab, rituximab, and sirolimus as well as UVA phototherapy or extracorporeal photochemotherapy.

CHRONIC Rx

- Treatment duration is unknown. Patients are monitored for clinical response, and medications are decreased/discontinued accordingly.
- Patients with incomplete response may require increased doses of corticosteroids.

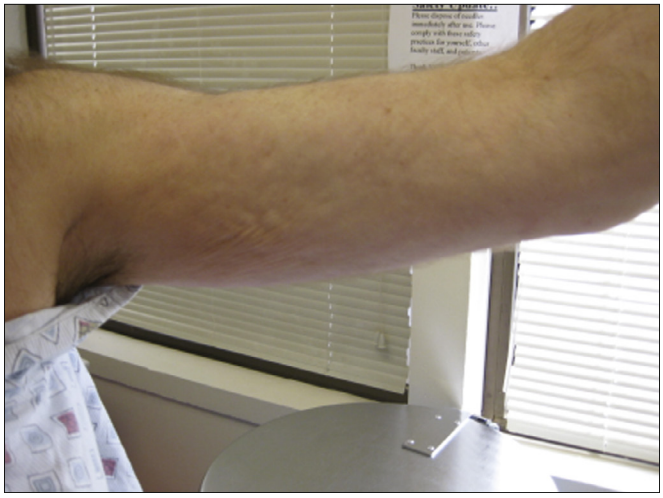

FIG. E1 The "groove sign" of eosinophilic fasciitis. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

DISPOSITION

- Improved outcomes with early treatment.
- Long-term prognosis is unknown but is generally good.
- Relapse can occur after cessation of steroids.

REFERRAL

Dermatology should be consulted for full skin-to-muscle biopsy. May require surgical evaluation to reduce contracture and maintain function.

PEARLS & CONSIDERATIONS

COMMENTS

- Physical therapy is a crucial, but often overlooked, part of managing EF.
- Patients should be started on prophylaxis for opportunistic infections when on long-term corticosteroids or immunosuppression.

Eosinophilic Granulomatosis with Polyangiitis

BASIC INFORMATION

DEFINITION

Eosinophilic granulomatosis with polyangiitis (EGPA), formerly known as Churg-Strauss syndrome (CSS) and also as allergic granulomatosis and angiitis, refers to a multisystem granulomatous vasculitis characterized by severe asthma, chronic rhinosinusitis, and hypereosinophilia. Classification criteria and definition for EGPA are described in Table E1.

SYNONYMS

Allergic angiitis
Allergic granulomatosis
Allergic granulomatosis and angiitis
Churg-Strauss syndrome (CSS)
EGPA

ICD-10CM CODES

M31.30 Wegener granulomatosis without renal involvement

EPIDEMIOLOGY & DEMOGRAPHICS

- Overall incidence of 2.4 cases per 1 million persons in the U.S. Among patients with asthma, the annual incidence of EPGA is estimated to average 34.6 per 1 million patients.
- Usually occurs at a mean age of 40 yr, and is uncommon in those ≥65 yr. It is rare in children but presents in an aggressive form with cardiopulmonary involvement when it does occur.
- No gender predominance.
- Rarest of the ANCA-associated vasculitis but most common of the p-ANCA vasculitides.
- Cardiac or GI involvement and age ≥65 yr are indicators of worse prognosis.
- With treatment, 1-yr survival rate is approximately 90%, and 5-yr survival is 62%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The clinical picture of EPGA typically consists of three partially overlapping phases, which may or may not be sequential:

- Prodromal phase:
  1. Severe adult-onset asthma, with or without allergic rhinitis, atopic dermatitis, sinusitis, headache, cough, and wheezing
  2. Precedes development of systemic vasculitis by several yrs
- Eosinophilic/tissue infiltration phase:
  1. Peripheral eosinophilia and eosinophilic infiltration of the lungs, myocardium, and GI tract, with or without granulomas
  2. Signs and symptoms of cough, fever, anorexia, weight loss, sweats, malaise, nausea, vomiting, abdominal pain, and diarrhea
  3. Forty percent of EGPA patients present with asthma, pulmonary opacities, and hypereosinophilia in this phase
- Systemic vasculitic phase:
  1. Development of necrotizing vasculitis that is clinically apparent primarily in peripheral nerves, skin, and kidneys, although any organ can be affected
  2. Signs and symptoms include fever, fatigue, weight loss
- Skin involvement is common and seen in >50% of patients. It can be divided into three categories:
  1. Erythematous maculopapules (can resemble erythema multiforme)
  2. Hemorrhagic lesions (associated with wheals)
  3. Cutaneous and subcutaneous nodules on extensor surfaces

ETIOLOGY

Etiology unknown but believed to be an autoimmune-mediated process (see "Comments")

DIAGNOSIS

- Clinical findings and biopsy showing eosinophilic vasculitis.
- The American College of Rheumatology (ACR) has established the criteria for EGPA diagnosis in patients without vasculitis (Table E1). The presence of any four or more of the six criteria yields a sensitivity of 85% and a specificity of 99.7%. For patients with vasculitis, the presence of asthma and eosinophilia is 90% sensitive and 99% specific for EGPA.

DIFFERENTIAL DIAGNOSIS

- Polyarteritis nodosa (PAN)
- Granulomatosis with polyangiitis and microscopic polyangiitis (GPA, formerly known as Wegener granulomatosis)
- Goodpasture syndrome
- Loeffler syndrome
- Hypereosinophilia syndrome
- Rheumatoid arthritis
- Leukocytoclastic vasculitis

Although similar and at times grouped with patients with PAN or GPA, EGPA differs in that:

- EGPA vasculitis involves small-sized arteries, veins, and venules.
- EGPA, unlike PAN, predominantly involves the lung.
- Kidney involvement is much less common in EGPA than in GPA. Pulmonary lesions in GPA usually involve the upper respiratory tract rather than the peripheral lung parenchyma in EGPA.
- EGPA shows necrotizing vasculitis along with eosinophilic granulomas.

LABORATORY TESTS

- Complete blood count with differential: Eosinophilia >10% is an American College of Rheumatology (ACR) diagnostic criterion.
- Blood urea nitrogen and creatinine may be mildly elevated, suggesting renal involvement.
- Urinalysis may show mild hematuria and proteinuria.
- 24-hour urine for protein; >1 g/day is a poor prognostic factor.
- Perinuclear antineutrophilic cytoplasmic antibody (P-ANCA) is found in 40% to 60% of patients. Negative ANCA does not rule out EGPA.
- Antiproteinase 3 (PR3) antibody positivity.
- IgE is commonly elevated.
- Elevation of aspartate aminotransferase, alanine aminotransferase, and creatinine phosphokinase may indicate liver or muscle (skeletal or cardiac) involvement.
- Rheumatoid factor may be positive.
- Biopsy helps confirm the diagnosis. Surgical lung biopsy is the gold standard. Transbronchial biopsy is rarely helpful. Necrotizing vasculitis and extravascular necrotizing granulomas, usually with eosinophilic infiltrates, are suggestive of EGPA. The presence of eosinophils in extravascular tissues is most specific for EGPA.

IMAGING STUDIES

- Chest radiograph is abnormal in eosinophilic and vasculitic phases: Asymmetrical bilateral patchy migratory infiltrates, interstitial lung disease, small pleural effusions, or nodular infiltrates (Fig. E1).
- Lung lesions in EGPA are noncavitating, as opposed to those in GPA.
- Paranasal sinus films may reveal sinus opacification, which is an ACR diagnostic criterion.
- Angiography is sometimes done in patients with mesenteric ischemia or renal involvement.

TABLE E1 Classification Criteria and Definition for Churg-Strauss Syndrome

Diagnosis Criteria	
American College of Rheumatology (Preferred; Requires 4 of 6)	**Lanham (Requires All 3)**
Asthma	Asthma
Eosinophilia (>10% total WBC count)	Eosinophilia (>10% WBC count or >1.5 × 10^9)
Neuropathy (mono- or polyneuropathy)	Systemic vasculitis affecting at least two or more extrapulmonary sites
Pulmonary infiltrates (migratory or transitory)	
Paranasal sinus abnormality (pain, tenderness, or radiologic abnormality)	
Extravascular eosinophils (in a biopsy containing an artery, arteriole, or venule)	

WBC, White blood cell.
From Hochberg MC, et al: *Rheumatology,* ed 5, St. Louis, 2011, Mosby.

TREATMENT

NONPHARMACOLOGIC THERAPY

Oxygen therapy in severe asthmatic exacerbations

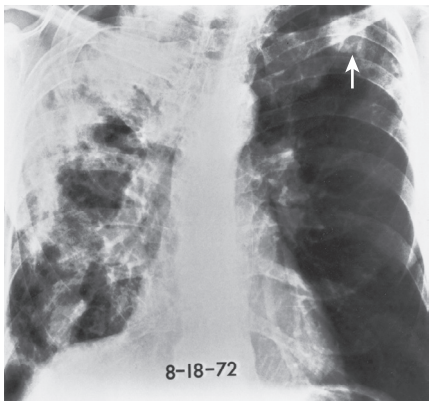

FIG. E1 Allergic angiitis and granulomatosis. Posteroanterior chest radiograph demonstrates peripheral air space consolidation in the right lung and a nodule *(arrow)* in the left upper lobe in this asthmatic patient. (From McLoud TC [ed]: *Thoracic radiology: the requisites,* St Louis, 1998, Mosby.)

PHARMACOLOGIC THERAPY

The following five factors suggest poor prognosis (five-factor score) and determine the aggressiveness of the immune suppressive therapy:

1. Proteinuria >1 g/day
2. Creatinine >1.58 mg/dl
3. Cardiovascular involvement
4. GI tract involvement
5. CNS involvement

ACUTE GENERAL Rx

- Corticosteroids are the treatment of choice if no poor prognostic factors are present. Prednisone 0.5 to 1.5 mg/kg/day is the starting dose and is continued for 6 to 12 wk and then tapered to 10 mg/day at 1 yr as clinical disease resolves. Response to steroids may be dramatic. Patients with extensive disease may require IV corticosteroids.
- A drop in the patient's eosinophil count and the ESR indicates a response to treatment. P-ANCA does not reliably correspond with disease activity.
- For severe disease, cyclophosphamide is used in combination with corticosteroids.

CHRONIC Rx

- In patients with one or more poor prognostic factors, immunosuppressant agents (cyclophosphamide 1 to 2 mg/kg/day) are used with corticosteroids as first-line therapy. The ideal duration of cyclophosphamide ranges from 6 to 12 mo.
- In patients who do not respond to corticosteroid treatment or in EGPA relapse, cyclophosphamide therapy is indicated as a second-line therapy.
- Azathioprine (2 mg/kg/day) or high-dose IV immunoglobulin has shown benefit in patients with severe disease and in patients unresponsive to corticosteroids.
- Corticosteroids, in combination with interferon-alpha, have also been used in refractory cases but may be difficult to tolerate.
- Patients with persistent symptoms of asthma will require long-term corticosteroids even if vasculitis is no longer present.
- Maintenance therapy using methotrexate (15 to 25 mg/wk) or azathioprine (2 mg/kg/day) is an alternative to cyclophosphamide.

DISPOSITION

- Clinical remission is obtained in more than 90% of patients after treatment. Relapse is common on cessation of therapy (~26%).
- Five-yr survival rate with treatment is between 60% and 90% and decreases to 50% at 7 yr. Asthma generally remains persistent, and ischemic damage to peripheral nerves can be permanent.
- The 5-yr survival rate of untreated EPGA is 25%.
- Death usually occurs from progressive refractory vasculitis, myocardial involvement (~50% of deaths), or severe GI involvement (mesenteric ischemia, pancreatitis).

REFERRAL

- A pulmonary referral for diagnosis and management is appropriate.
- Patients should be followed up closely by rheumatology. Patients usually need long-term immunosuppressive medications.

PEARLS & CONSIDERATIONS

COMMENTS

- EGPA is distinguished from other vasculitides by the nearly universal presence of adult-onset asthma that typically precedes all other symptoms. Family history is often negative for allergies or asthma.
- Vasculitis may not present until several yrs after the prodromal phase.
- Up to 77% of patients in the prodromal phase of EGPA require oral steroids for asthma control.
- Patients often have constitutional symptoms of weight loss, fever, and malaise before specific organ involvement is clinically evident.
- Peripheral nerve involvement from vasculitis of the vasa vasorum commonly manifests as mononeuritis multiplex. Patients may present with sudden foot or wrist drop, along with sensory deficits in the distribution of one or more distal nerves.
- Most patients with GI involvement are symptomatic. Gastroenteritis, acute abdomen, cholecystitis, hemorrhage, bowel perforation, and mesenteric ischemia have all been reported in patients with EGPA.
- Most patients with EGPA respond to corticosteroid treatment and do not require cytotoxic therapy.
- Symptoms of GPA typically appear as oral corticosteroids are being decreased or discontinued for the treatment of asthma and not triggered by leukotriene receptor-1 antagonists, as previously reported.
- Compared with GPA, patients more often present with history of atopy, asthma, or allergic rhinitis. When present, eosinophilia in EGPA is often >1000 eosinophils/mm^3 compared with GPA, in which eosinophilia is much milder (<500 eosinophils/mm^3).
- The heart is involved in up to 60% of patients with EGPA and represents a major cause of mortality.

BASIC INFORMATION

DEFINITION

Eosinophilic pneumonias (EPs) are a group of disorders characterized by pulmonary infiltrates, eosinophilia of the pulmonary parenchyma or airways, and in some cases, peripheral blood eosinophilia. They manifest by different radiologic and clinical syndromes.

SYNONYMS

EP
Simple pulmonary eosinophilia
Chronic eosinophilic pneumonia
Acute eosinophilic pneumonia
Eosinophilic granulomatosis with polyangiitis (formerly Churg-Strauss syndrome)
Idiopathic hypereosinophilic syndrome
Allergic bronchopulmonary aspergillosis
Parasite-induced, fungal-induced, and drug-induced pulmonary eosinophilia

ICD-10CM CODE

J82 Pulmonary eosinophilia, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

Vary depending on the specific cause

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever, cough, and shortness of breath
- Vary depending on the specific cause

ETIOLOGY

SIMPLE PULMONARY EOSINOPHILIA (LÖFFLER SYNDROME):

- Often associated with helminth infections, which can cause pulmonary eosinophilia by transpulmonary passage of larvae, pulmonary parenchymal invasion, or hematogenous spread.
- Can also be seen as the result of a hypersensitivity reaction to infectious organisms or drugs.
- Presents as transient pulmonary infiltrates and peripheral eosinophilia.
- Symptoms are usually mild and self-limited and include fever, cough, and dyspnea.
- Treatment includes removing the offending agent and antimicrobial therapy if appropriate.

IDIOPATHIC ACUTE EP:

- Acute onset of fever, cough, dyspnea (<1 mo).
- Often presents with acute respiratory failure (PaO_2 <60%), requiring intensive care.
- Bilateral diffuse infiltrates on chest radiograph.
- High-resolution computed tomography (CT) scan of the chest typically demonstrates patchy ground glass and reticular opacities; small bilateral pleural effusions are also common.
- Bronchoalveolar lavage (BAL) eosinophilia >25%.
- Absence of infection or other known causes of eosinophilic pneumonia.
- Associations: Recent onset of tobacco smoking, drugs, occupational exposures, exposure to World Trade Center dust, and military exposures in the Middle East.
- Steroids lead to rapid improvement, although there is no consensus about ideal dosing strategy.
- Relapse is uncommon, and prognosis is excellent if promptly treated.

IDIOPATHIC CHRONIC EP:

- Often occurs in middle age and is more commonly seen in women and nonsmokers.
- Associated with asthma.
- Absence of infection or other cause.
- Presentation over weeks to months.
- Symptoms include productive cough, dyspnea, weight loss, night sweats, and fever.
- Chest radiograph typically shows bilateral pulmonary infiltrates.
- "Photographic negative" pulmonary edema (peripheral or pleural based opacities) is highly suggestive but only present in 25% of cases.
- High-resolution CT of the chest may reveal atelectasis, pleural effusions, lymphadenopathy, and septal thickening.
- Pulmonary function tests are nonspecific and often show mixed restrictive and obstructive pattern. Reduced diffusion capacity is also common.
- Peripheral blood eosinophilia is almost always present.
- Diagnose by BAL (almost all cases have >25% eosinophils). Lung biopsy is rarely needed but typically shows interstitial and alveolar infiltrate with eosinophils.
- Treatment with glucocorticoids is typically rapidly effective.
- Relapses are common when glucocorticoids are tapered or discontinued and prolonged steroid courses are often required.
- Case reports suggest inhaled steroids and omalizumab may be helpful in patients with prolonged steroid dependence.
- Prognosis is typically excellent.

ALLERGIC BRONCHOPULMONARY ASPERGILLOSIS (ABPA):

- Hypersensitivity reaction to *Aspergillus fumigatus*
- Frequently associated with asthma and cystic fibrosis
- Often presents as severe, persistent asthma, resistant to treatment. Symptoms also include fever, myalgias, cough, wheezing, expectoration of brown-black mucous plugs, and rarely hemoptysis
- A patient with chronic asthma with a component of bronchiectasis and pulmonary infiltrates should be evaluated carefully for ABPA
- Imaging typically shows recurrent (sometimes migratory) infiltrates, central bronchiectasis, and endobronchial mucous impaction ("finger in glove")
- Laboratory tests commonly show peripheral eosinophilia, elevated serum IgE, and elevated sputum and BAL eosinophilia
- Pulmonary function tests commonly show reversible airflow obstruction
- Major diagnostic criteria:
  1. History of asthma or cystic fibrosis
  2. Positive skin test to *Aspergillus* or increased *Aspergillus fumigatus*–specific IgE
  3. Precipitating serum antibodies to *Aspergillus*
  4. Radiographic opacities consistent with ABPA
  5. Serum eosinophilia >500 cells/ml

The disease has been characterized by a staging system. Patients do not necessarily proceed from one stage to another.

Stage I	Acute phase
Stage II	Remission
Stage III	Exacerbation
Stage IV	Glucocorticoid-dependent ABPA
Stage V	End-stage (fibrotic) ABPA

- Treatment: Systemic corticosteroids are the mainstay of treatment. Antifungals may provide additional benefit in modulating airway fungal burden and are recommended for use in patients with relapse or glucocorticoid-dependent disease.
- Development of bronchiectasis portends a worse prognosis.
- Response to therapy and activity of disease may be monitored by measuring IgE levels, which typically will decrease by 35% to 50% when a patient is in remission.

TROPICAL PULMONARY EOSINOPHILIA:

- Onset of asthma, fever, paroxysmal cough and bronchospasm, marked peripheral blood eosinophilia
- Basilar reticulonodular and interstitial infiltrates
- High serum IgE levels
- Presumed etiology: Filariasis *(Wuchereria bancrofti* and *Brugia malayi)*
- Treatment is with diethylcarbamazine

EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA):

- Formerly known as Churg-Strauss syndrome.
- Eosinophilic granulomatous inflammation and necrotizing vasculitis of small- to medium-size vessels that involves many organ systems in the setting of asthma.
- Patients present with signs of asthma and atopy including cough, dyspnea, wheezing, sinusitis, and allergic rhinitis; other symptoms depend on other organs involved.
- Labs reveal peripheral blood eosinophilia, elevated IgE.
- 40% of patients will have a positive ANCA (p-ANCA more common than c-ANCA).
- Imaging may show patchy opacities, consolidation, or nodules.
- Pulmonary function test may reveal airflow obstruction.
- Organ systems involved include lungs, heart, skin, peripheral nervous system, GI tract, and kidneys.

- Pathogenesis is not clearly known.
- Untreated mortality is high, but remission is common with treatment.
- Treatment includes steroids and other immunosuppressive agents.

HYPEREOSINOPHILIC SYNDROME:

- A disease of persistently elevated peripheral eosinophils (>6 mo) of unknown etiology with tissue hypereosinophilia, resulting in end organ damage.
- Can involve multiple organs, including the heart, lungs, nervous system, and GI tract.
- Cardiac disease can be severe, including valvular disease and myocardial fibrosis.
- Presentation often depends on the organ systems involved but can include fever, cough, weight loss, wheezing, or CNS abnormalities.
- In addition to the idiopathic form, may have a myeloproliferative etiology.
- Lungs are affected in 25% of patients.
- Chest imaging may show opacities, consolidation, or lymphadenopathy.
- Diagnosis of exclusion.
- Check echocardiogram.
- Treat with steroids if symptomatic or evidence of end-organ dysfunction (particularly cardiac disease).
- Patients with myeloproliferative disease associated hypereosinophilic syndrome with *FIP1L1-PDGFRA* fusion gene mutations typically have an aggressive course and are treated with imatinib.

DRUG- OR TOXIN-INDUCED EOSINOPHILIC PNEUMONIA:

- Can have several different clinical presentations, including simple pulmonary eosinophilia, chronic eosinophilic pneumonia, acute eosinophilic pneumonia, or drug reaction with eosinophilia and systemic symptoms (DRESS).
- Described causes of drug- or toxin-induced EP: Most commonly associated with antibiotics and NSAIDs. Others include amiodarone, bleomycin, captopril, iodine, methotrexate, venlafaxine, sulfa-containing drugs, illicit drugs, dust exposure, and so on.
- Consider DRESS when pulmonary symptoms are also associated with skin eruption and fevers.
- Imaging findings are nonspecific and can include bilateral infiltrates.
- Diagnostic evaluation often includes BAL to exclude infection or other lung disease.
- Laboratory evaluation rarely diagnostic.
- Treatment includes removal of the offending agent and sometimes steroids.

Dx DIAGNOSIS

- Diagnosis varies depending on specific cause of pneumonia.
- Usually involves chest radiograph (Fig. E1), CT, peripheral eosinophil count, BAL, and possibly lung biopsy.

DIFFERENTIAL DIAGNOSIS

- Bacterial pneumonia
- Tuberculosis

FIG. E1 Chest radiograph shows pattern of peripheral pulmonary infiltrates characteristic of chronic eosinophilic pneumonia. (From Weinberger SE: *Principles of pulmonary medicine,* ed 7, Philadelphia, 2019, Elsevier.)

- Fungal pneumonia
- Parasitic infection *(Ascaris, Strongyloides)*
- Idiopathic pulmonary fibrosis
- Bronchiolitis obliterans and organizing pneumonia
- Hypersensitivity pneumonitis
- Radiation pneumonitis
- Bronchogenic carcinoma
- Rheumatoid lung disease
- Sarcoidosis

WORKUP

Physical examination, laboratory tests, imaging, bronchoscopy

LABORATORY TESTS

- WBC counts are often normal
- Often peripheral blood eosinophilia
- Elevated eosinophil count on BAL
- Consider ANCA, stool O+P, parasite serologies, IgE, *Aspergillus* precipitins, rheumatologic serologies as appropriate based on history and examination

IMAGING STUDIES

Chest radiograph may show a variety of infiltrates depending on the cause of EP. CT demonstrates a more characteristic pattern and distribution of parenchymal opacities than chest radiography.

Rx TREATMENT

- Varies depending on the cause.
- Remove offending agent or treat with appropriate antibiotic.
- Steroids may be helpful in many cases; doses and length of treatment depend on etiology of symptoms and response to treatment.
- There have been recent case reports of successful use of omalizumab (Xolair) as a steroid-sparing agent in the treatment of chronic eosinophilic pneumonia, although this practice is not well examined in the literature to date.
- Supportive respiratory care.

DISPOSITION

Depends on etiology. Prognosis is good if offending agent can be removed or an infectious etiology treated. Glucocorticoids have a good effect, but relapse often recurs with tapering in chronic idiopathic cases.

REFERRAL

To pulmonologist if a BAL or lung biopsy is needed to establish the diagnosis

! PEARLS & CONSIDERATIONS

- History (including travel) and physical examination are most important. Temporal association of eosinophilia and pulmonary abnormalities is an important diagnostic clue.
- Coccidioidomycosis and *Aspergillus* can present as eosinophilic lung disease and are important to recognize because steroid therapy can produce progressive infection.
- *Aspergillus* from respiratory specimens does not always indicate true infection and may be colonization.

- Blood eosinophilia >1 × 10^9 eosinophils/L or BAL >25% is helpful in narrowing diagnosis.
- Integrating the clinical, radiologic, and pathologic findings facilitates the initial and differential diagnoses of various eosinophilic lung diseases.

BASIC INFORMATION

DEFINITION

Epicondylitis is an overuse injury of the common extensor tendon origin at the lateral epicondyle (tennis elbow) and common flexor tendon origin at the medial epicondyle (golfer elbow). The term *epicondylitis* is a misnomer because the tendon, rather than the epicondyle, is primarily involved in this degenerative process, and histologic changes are characterized by angiofibroblastic hyperplasia, rather than inflammatory changes.

SYNONYMS

Tennis elbow (lateral epicondylitis)
Golfer elbow (medial epicondylitis)
Elbow tendinosis
Elbow tendinopathy
Epicondylalgia
Elbow tendinitis

ICD-10CM CODES

M77.00	Medial epicondylitis, unspecified elbow
M77.10	Lateral epicondylitis, unspecified elbow
M77.01	Medial epicondylitis, right elbow
M77.02	Medial epicondylitis, left elbow
M77.11	Lateral epicondylitis, right elbow
M77.12	Lateral epicondylitis, left elbow
M77.0	Medial epicondylitis
M77.1	Lateral epicondylitis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE

- 1% to 3% of the general population.
  1. 90% of cases of tennis elbow are not related to playing tennis. Recreational tennis players who play >2 h/d have two to four times greater risk of developing epicondylitis compared with the general population.
  2. Smoking, obesity, repetitive movement for more than 2 h daily, and forceful activity are risk factors in the general population.
- The lateral side is involved more often than the medial.

PREDOMINANT AGE AND SEX:

- Affects middle-aged women more often than men.
- More common in individuals 40 to 60 yr old.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Main symptom is pain in lateral or medial elbow.
  1. Pain is typically related to activity.
  2. Physical examination maneuver to provoke pain: Wrist extension against resistance tests for lateral epicondylitis and wrist flexion against resistance for medial epicondylitis. Local tenderness is experienced over the affected epicondyle (Figs. E1 and E2).

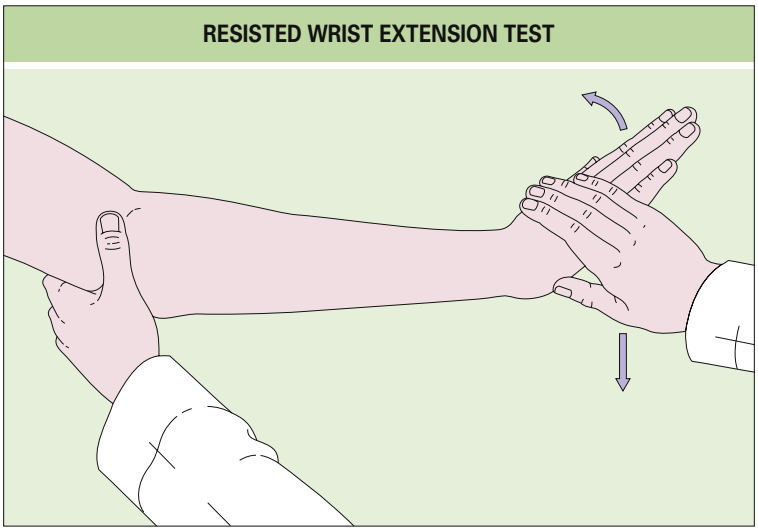

FIG. E1 Resisted wrist and long finger extension. Patients with lateral epicondylitis normally experience increased pain as this test is performed. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

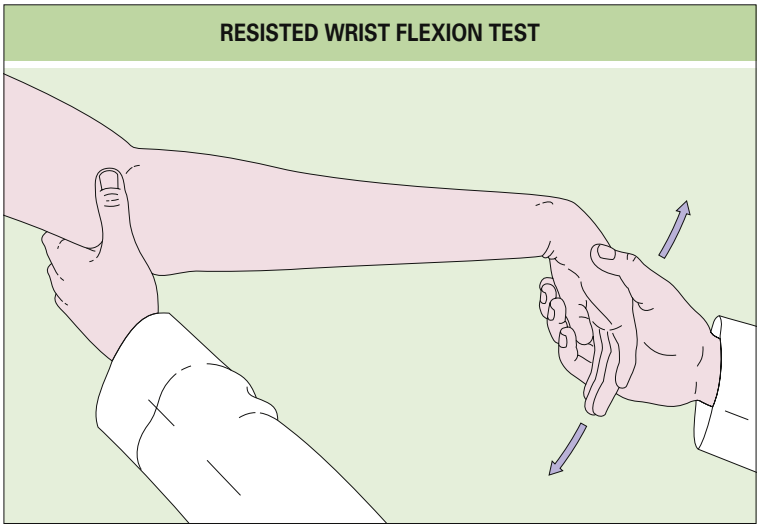

FIG. E2 Resisted wrist flexion with the elbow in extension. This normally increases medial elbow pain in patients with medial epicondylitis. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

ETIOLOGY

- Epicondylitis is thought to be secondary to repetitive microtrauma, leading to degeneration, tendinosis, and possibly tendon tear, which results in a robust angiogenic and fibroblastic response.
- The pathology is defined by a disorganization of normal collagen by invading fibroblasts in association with an immature vascular reparative response and the **absence of inflammatory cells,** which is termed *angiofibroblastic tendinosis.*
- Although classic inflammatory changes are not present, cytokines have been shown to play a role in the cause of epicondylitis.

GENETICS

Patients with BstUI and DpnII variants of the *COL5A1* gene are at increased risk for development of lateral epicondylitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intraarticular elbow pathology (osteoarthritis, osteochondritis dissecans, loose body)
- Radial tunnel syndrome (compression of the posterior interosseous nerve)
- Cubital tunnel syndrome (compression of the median nerve)
- Medial collateral ligament instability
- Valgus extension overload
- Ulnar neuritis
- Tumors
- Avascular necrosis
- Thoracic outlet syndrome
- Cervical radiculopathy

IMAGING STUDIES

- Plain radiography is useful for chronic cases to evaluate for osteoarthritis, exostosis, or other bony abnormalities.

- Ultrasound may show tendinosis as hypoechoic swelling of the involved tendon, possible hyperechoic calcification, and bony abnormality. Power or color Doppler signal is variable.
- MRI is the gold standard in detecting epicondylitis. MRI is the most sensitive test, showing tendon thickening and high T2 signal intensity.

Rx TREATMENT

- Rest, activity modification, and overuse prevention.
- Athletes may benefit from technique modifications.
- Ice packs and heat may be beneficial.
- Nonsteroidal antiinflammatory drugs (NSAIDs) can be used topically or orally but usually provide only short-term relief.
- Local steroid/lidocaine injection (Fig. E3) can be considered, but recent trials have called into question the long-term efficacy of corticosteroid injections for epicondylitis.
- Wrist brace or splint.
- Physical therapy with isometric strengthening exercises. Tendon fenestration (tenotomy or dry needling) has been deployed in ultrasound-guided treatment of lateral epicondylitis with some success. A recent small study reports short-term benefit of Kinesiotaping and extracorporeal shock wave therapy (ESWT) in treatment of lateral epicondylitis.
- Acupuncture has been found to be beneficial in some cases.
- Local injection of platelet-rich plasma has been investigated to a limited extent for use in the treatment of lateral epicondylitis with some evidence of improvement in pain and function.
- Autologous blood and prolotherapy are also currently used in clinical practice.
- Injection of botulinum toxin A at the myotendinous junction has been found to be helpful in a small randomized controlled trial.
- Patients with refractory symptoms after 6 mo of nonoperative management may benefit from surgical intervention.

DISPOSITION

- Epicondylitis is self-limited in most cases. Resolution of symptoms may take months to years.
- Prognosis is worse in the following situations:
  1. The dominant hand is involved.
  2. Patient experiences high physical strain at work.
  3. Duration of symptoms is more than 3 mo.
  4. Patient experiences severe pain at presentation and concomitant neck pain.

REFERRAL

If symptoms do not respond to a 6-mo trial of conservative therapy, surgical referral is appropriate.

PEARLS & CONSIDERATIONS

- The lateral epicondyle may be harder to localize than bony medial epicondyle.
- The diagnosis can frequently be made with physical examination and history alone.
- The majority of cases are self-resolving.

BASIC INFORMATION

DEFINITION

Epidermolysis bullosa (EB) is a rare disorder presenting in adults with the development of blisters on the hands, feet, elbows, knees, and other body regions after mild trauma. It represents a group of genetic disorders characterized by mechanically fragile skin with a propensity to develop blisters and/or erosions. There are four major types: dystrophic (DEB), junctional (JEB), simplex (EBS), and ***Kindler syndrome.*** They differ in the ultrastructural site within which cutaneous blisters form. Kindler syndrome is an extremely rare form characterized by trauma-induced blistering, photosensitivity, progressive poikiloderma, cutaneous atrophy, and mucosal inflammation. Characteristics of major forms of EBS, basal are summarized in Table E1. The characteristics of the major forms of JEB are described in Table E2.

SYNONYMS

EB
Kindler syndrome

ICD-10CM CODES

L12.30	Acquired epidermolysis bullosa, unspecified
Q81.2	Epidermolysis bullosa dystrophica
Q81.0	Epidermolysis bullosa simplex
Q81.9	Epidermolysis bullosa, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE AND INCIDENCE: The estimated overall prevalence and incidence of EB in the U.S. are 11.1 per 1 million population and 19.6 per 1 million live births, respectively. The approximate prevalences and incidences, respectively, of the major types of EB are as follows: EB simplex, 6.0 and 7.9; junctional EB, 0.5 and 2.7; dominant dystrophic EB, 1.5 and 2.1; and recessive dystrophic EB, 1.4 and 3.0.

GENETICS: The most common forms of EB simplex (EBS) are transmitted in an autosomal dominant manner. Table E3 summarizes the various clinical phenotypes and inheritance.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

EB is marked by development of painful blisters on the hands, feet (Fig. E1), elbows, and knees after mild trauma. Extensive blistering (Fig. E2) may occur. EB may also be complicated by atrophic scarring, milia formation, and nail dystrophy. Fig. E3 illustrates helpful cutaneous findings in patients with EB.

Table E4 summarizes major extracutaneous complications of EB.

ETIOLOGY

This is an inherited disorder (see Table E3).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bullous pemphigoid
- Pemphigus vulgaris
- Linear IgA bullous dermatosis

TABLE E1 Characteristics of Major Forms of Epidermolysis Bullosa Simplex, Basal

Type	Clinical Manifestations
EBS, localized (formerly Weber-Cockayne)	Easy blistering on palms and soles
	May be focal keratoderma of palms and soles in adults
	25% show oral mucosal erosions
	Rarely show reticulated pigmentation, especially on arms and trunk and punctate keratoderma (EBS with mottled pigmentation)
EBS, generalized, intermediate (formerly Koebner)	Generalized blistering
	Variable mucosal involvement
	Focal keratoderma of palms and soles
	Nail involvement in 20%
	Improves with advancing age
EBS, generalized, severe (formerly Dowling-Meara)	Most severe in neonate, infant; improves beyond childhood
	Large, generalized blisters; later, smaller (herpetiform) blisters
	Mucosal blistering, including esophageal
	Nails thickened, shed but regrow
	May have natal teeth
EBS with mottled pigmentation	Reticulated hyperpigmentation, especially on arms and trunk
	Punctate keratoses and keratoderma

EBS, Epidermolysis bullosa simplex.
From Paller AS, Mancini AJ (eds): *Hurwitz clinical pediatric dermatology,* ed 5, Philadelphia, 2016, Elsevier, Table 13.2, p. 319, in Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

TABLE E2 Characteristics of Major Forms of Junctional Epidermolysis Bullosa

Type	Clinical Manifestations
JEB, generalized severe (formerly Herlitz)	50% of patients die by 2 yr old
	Blisters heal with atrophic scarring but no milia
	Periungual and fingerpad blistering, erythema
	Blistering of oral and esophageal mucosae
	Laryngeal and airway involvement with early hoarseness
	Later, perioral granulation tissue with sparing of lips
	Anonychia
	Dental enamel hypoplasia, excessive caries
	Growth retardation
	Anemia
JEB, generalized, intermediate (formerly non-Herlitz)	Less severe, but similar manifestations to Herlitz type, including dental, nail, and laryngeal involvement
	Granulation tissue is rare
	Perinasal cicatrization
	Less mucosal involvement
	Alopecia
	Anemia, but not as severe as JEB, generalized severe
JEB, localized	Localized blisters without residual scarring or granulation tissue
	Minimal mucosal involvement
	Dental and nail abnormalities as in JEB, generalized severe
JEB, generalized with pyloric atresia	Usually lethal in neonatal period
	Generalized blistering, leading to atrophic scarring
	May be born with large areas of cutis aplasia
	No granulation tissue
	Nail dystrophy or anonychia
	Pyloric atresia, genitourinary malformations
	Rudimentary ears
	Dental enamel hypoplasia (survivors)
	Variable anemia, growth retardation, mucosal blistering

JEB, Junctional epidermolysis bullosa.
From Paller AS, Mancini AJ (eds): *Hurwitz clinical pediatric dermatology,* ed 5, Philadelphia, 2016, Elsevier, Table 13.4, p. 321, in Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

TABLE E3 Epidermolysis Bullosa: Simplex, Junctional, and Dystrophic Subtypes and Kindler Syndrome

Entities with a lighter background represent rare variants.

EPIDERMOLYSIS BULLOSA: SIMPLEX, JUNCTIONAL AND DYSTROPHIC SUBTYPES AND KINDLER SYNDROME		
Subtype	**Inheritance**	**Defective protein(s)**
Suprabasal intraepidermal cleavage		
Acral peeling skin syndrome	AR	Transglutaminase 5
EB superficialis	Unknown	Unknown
Acantholytic EBS	AR	Desmoplakin; plakoglobin
Skin fragility syndromes		
Desmoplakin deficiency (skin fragility–woolly hair syndrome)	AR	Desmoplakin
Plakoglobin deficiency	AR	Plakoglobin
Plakophilin deficiency (skin fragility–ectodermal dysplasia syndrome)	AR	Plakophilin 1
Basal intraepidermal cleavage		
EBS, localized (formerly Weber–Cockayne)	AD	Keratins 5 and 14
EBS, generalized severe (formerly Dowling–Meara)		
EBS, generalized intermediate		
EBS with mottled pigmentation	AD	Keratin 5
EBS, migratory circinate		
EBS, AR-KRT14	AR	Keratin 14
EBS due to KLHL24	AD	Kelch-like protein 24
EBS with muscular dystrophy	AR	Plectin
EBS with pyloric atresia	AR	Plectin; $\alpha_6\beta_4$ integrin
EBS-Ogna	AD	Plectin
EBS, AR-BP230 deficiency	AR	Bullous pemphigoid antigen 1 (BP230)
EBS, AR-exophilin 5 deficiency	AR	Exophilin 5
Intra-lamina lucida cleavage		
JEB, generalized severe (formerly Herlitz)	AR	Laminin 332
JEB, generalized intermediate	AR*	Laminin 332; collagen XVII
JEB with pyloric atresia	AR	$\alpha_6\beta_4$ integrin
JEB, late onset	AR	Collagen XVII
JEB with respiratory and renal involvement	AR	α_3 integrin subunit
JEB, localized	AR	Collagen XVII; $\alpha_6\beta_4$ integrin
JEB, inversa	AR	Laminin 332
JEB-laryngo-onycho-cutaneous syndrome	AR	Laminin α3 chain (an isoform)
Sublamina densa cleavage		
DDEB, generalized	AD	Collagen VII
Other DDEB variants: acral, pretibial, pruriginosa, nails only		
DDEB, bullous dermolysis of the newborn		
RDEB, generalized severe (formerly Hallopeau–Siemens)	AR	
RDEB, generalized intermediate		
RDEB, inversa		
Other RDEB variants: localized, pretibial, pruriginosa, centripetalis		
RDEB, bullous dermolysis of the newborn		
Mixed cleavage planes		
Kindler syndrome	AR	Kindlin-1
*One case with AD inheritance has been reported.		

AD, Autosomal dominant; *AR,* autosomal recessive; *DDEB,* dominant dystrophic EB; *EB,* epidermolysis bullosa; *EBS,* epidermolysis bullosa simplex; *JEB,* junctional epidermolysis bullosa; *RDEB,* recessive dystrophic EB.

From Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

FIG. E1 Localized epidermolysis bullosa simplex. A and **B,** Bullae arising on the toes and plantar surfaces at sites of lateral or rotary traction. The majority of blisters occur in acral sites. (**A,** From Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier. **B,** Courtesy Julie V. Schaffer, MD)

- Porphyria cutanea tarda
- Chemical burn
- Thermal burn
- Blisters due to trauma (friction blisters)
- Cicatricial pemphigoid

WORKUP

An approach to the laboratory diagnosis of EB is illustrated in Fig. E4.

LABORATORY TESTS

Skin biopsy and serum for direct and indirect immunofluorescence can detect skin basement membrane–specific autoantibodies.

Rx TREATMENT

ACUTE GENERAL Rx

- Nutritional support, avoidance of trauma
- Topical antibiotics, sterile dressing
- Dressings frequently used in patients with EB are described in Table E5
- Systemic corticosteroids
- Dapsone
- Azathioprine
- Colchicine
- Cyclosporine

CHRONIC Rx

The management of long-term complications of EB is summarized in Table E6.

REFERRAL

Dermatology in all cases

PEARLS & CONSIDERATIONS

COMMENTS

Workup for inflammatory bowel disease and ELISA for type VII collagen-specific autoantibodies should also be considered.

TABLE E5 Dressings Frequently Used in Patients with Epidermolysis Bullosa

Dressing Type	Use	Examples®,™
Soft silicone dressings ("low-tack")	• Suitable as primary or secondary dressings in many types of EB • May have a foam backing for mechanical protection or to wick exudate away from the wound	Mepitel, Mepilex, Mepilex Transfer, Mepilex Border
Nonadherent lipido-colloid dressings	• Suitable for primary contact	UrgoTul
Hydrogel dressings	• Provide moisture to drier wounds to facilitate healing • May provide relief from pain or itch	Flexigel, Curagel, ActiFormCool
Foam dressings	• Useful to absorb moderate amounts of wound exudate	Mepilex, Allevyn
Absorptive dressings	• Useful to absorb heavy amounts of wound exudate	Eclypse, Sorbion Sana
Silver-containing dressings	• Clinically infected or highly colonized wounds • Avoid prolonged use due to risk of silver absorption	UrgoTul SSD, Mepilex AG
Other antimicrobial dressings	• Clinically infected or highly colonized wounds	PolyMem, Cutimed Sorbact, Activon Tulle, Suprasorb X + PHMB

EB, Epidermolysis bullosa.
From Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

TABLE E6 Management of Long-Term Complications of Epidermolysis Bullosa

Complication	Prevention and Monitoring/Detection	Management
Oral and Gastrointestinal		
Excessive caries	• Diligent oral hygiene • Antiseptic and fluoride mouthwashes • Periodic evaluation and cleaning by a dentist	• Restorative dentistry
Microstomia		• Physical therapy • "Mouth expanding" devices
Oral ulceration		• Topical antiseptics, topical NSAIDs, barrier preparations (e.g., sucralfate suspension)
Esophageal strictures	• Evaluate dysphagia with contrast studies	• Dietary modification (soft foods/purées, caloric supplementation) • Fluoroscopically guided balloon dilatation; repeated procedures are often required • In severe and recalcitrant cases, surgical options include colonic interposition
Gastroesophageal reflux disease		• Proton pump inhibitors, H_2 blockers, prokinetic agents (e.g., metoclopramide, domperidone [not available in the U.S.])
Constipation	• Ensure adequate fluid intake and dietary fiber	• Osmotic laxatives (e.g., containing polyethylene glycol), mineral oil • Avoid suppositories and enemas
Nutritional		
Growth retardation/inadequate intake to meet nutritional needs	• Monitor height, weight, and body mass index • Periodically assess serum zinc, selenium, iron, vitamin D, and carnitine levels (e.g., yearly) • Oral supplements to optimize intake of calories, protein, vitamins, and minerals	• Consider gastrostomy feedings
Hematologic		
Anemia due to iron deficiency and chronic inflammation	• Monitor CBC and measures of iron stores	• Iron supplementation (oral or IV) • Consider erythropoietin or darbepoetin alpha • Consider blood transfusion if hemoglobin ≤7-8 g/dl and/or symptomatic
Genitourinary and Renal		
Urinary outflow obstruction (e.g., urethral or ureteral strictures)	• Consider annual ultrasound of the urinary tract and urodynamic studies (especially for JEB)	• Dilatation procedures as needed to treat obstruction • Avoid unnecessary instrumentation
Renal disease (e.g., hydronephrosis, postinfectious glomerulonephritis, renal amyloidosis, IgA nephropathy)	• Blood urea nitrogen and serum electrolyte levels, urinalysis, and blood pressure evaluation every 6 mo in RDEB patients • Adequately treat streptococcal infections	• Hemodialysis or peritoneal dialysis if renal failure develops
Musculoskeletal		
Osteopenia and osteoporosis	• Annual DEXA scan and spinal radiographs beginning at age 5 yr in RDEB and JEB patients • Calcium and vitamin D supplementation	• Consider IV bisphosphonate therapy
Pseudosyndactyly of hands/feet	• Cushioned splints on hands/forearms and individual wrapping of fingers in RDEB patients	• Surgery to release contractures and webbing

Continued

TABLE E6 Management of Long-Term Complications of Epidermolysis Bullosa—cont'd

Complication	Prevention and Monitoring/Detection	Management
Oncologic		
Cutaneous squamous cell carcinoma	• Periodic total-body skin examinations; for RDEB patients, approximately every 3-6 mo beginning at age 10 yr and every 3 mo after age 16 yr • Biopsy or monitor nonhealing ulcers • Consider taking serial photographs	• Excision ± skin grafting (sometimes amputation); consider MRI to assess extent of local disease • Consider staging with CT, PET-CT, sentinel lymph node biopsy
Ocular		
Chronic complications include corneal scarring, symblepharon, ectropion	• Periodic ophthalmologic evaluation for patients with eye involvement • Lubricating eye drops	• Surgical procedures, e.g., division of symblepharon, amniotic membrane transplantation
Cardiac		
Dilated cardiomyopathy	• Consider annual echocardiography beginning in late childhood for RDEB patients	• Medical management • Supplement selenium and carnitine if deficient
Psychological and Psychiatric		
Disrupted family unit (e.g., via divorce)	• Consider family counseling, support groups	• Psychological/family counseling
Depression and suicidal ideation/ attempts	• Consider psychological counseling, support groups	• Psychiatric evaluation, antidepressant therapy

CBC, Complete blood count; *CT,* computed tomography; *DEXA,* dual-energy x-ray absorptiometry; *EB,* epidermolysis bullosa; *Ig,* immunoglobulin; *IV,* intravenous; *JEB,* junctional EB; *MRI,* magnetic resonance imaging; *NSAID,* nonsteroidal antiinflammatory drug; *PET-CT,* positron emission tomography and computed tomography; *RDEB,* recessive dystrophic EB.
Modified from Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

Epididymitis PTG

BASIC INFORMATION

DEFINITION

- Epididymitis is an inflammatory reaction of the epididymis caused by either an infectious agent or local trauma. In most cases of acute epididymitis, the testis is also involved (orchitis).
- Epididymitis is considered chronic if lasting ≥6 wk. Chronic epididymitis has been subcategorized into inflammatory chronic epididymitis, obstructive chronic epididymitis, and chronic epididymalgia.

SYNONYMS

Nonspecific bacterial epididymitis
Sexually transmitted epididymitis

ICD-10CM CODES

N45.1	Epididymitis
A54.00	Gonococcal infection of lower genitourinary tract, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Cause of >600,000 visits to physicians per yr
PEAK INCIDENCE: Sexually active yrs
PREDOMINANT SEX: Exclusive to males
PREDOMINANT AGE: All ages affected but usually in sexually active men or older males
CONGENITAL: Congenital urologic structural disorders possibly predisposing to infections

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Tender swelling of the scrotum with erythema, usually unilateral testicular pain and tenderness
- Dysuria and/or urethral discharge
- Fever and signs of systemic illness (less common)
- Pain and redness on scrotal examination
- Hydrocele or even epididymo-orchitis, especially late
- Chronic draining scrotal sinuses with a "beadlike" enlargement of the vas deferens in tuberculous disease

ETIOLOGY

- In young, sexually active men (<35 yr of age), the most common causes of infections are *Neisseria gonorrhoeae* and *Chlamydia trachomatis.*
- In older men (>35 yr of age) or those with underlying urologic disease:
  1. Gram-negative aerobic rods are predominant (i.e., *Escherichia coli*).
  2. Similar organisms are found in men following invasive urologic procedures.
  3. Gram-positive cocci are rarely seen in these groups.
  4. Mycobacteria may also be a cause of epididymitis.
- Acute epididymitis caused by sexually transmitted enteric organisms (e.g., *Escherichia coli*) also occurs among men who are the insertive partner during anal intercourse.
- Young, prepubertal boys may present with epididymitis caused by coliform bacteria; almost always a complication of underlying urologic disease such as reflux.
- In AIDS patients, CMV and *Salmonella* epididymitis have been described. CMV may have a negative urine culture. Toxoplasmosis and *Cryptococcus* should also be considered as a cause of epididymitis in AIDS patients.
- Chronic infectious epididymitis is most frequently seen in conditions associated with granulomatous reaction; mycobacterium tuberculosis is the most common granulomatous disease affecting the epididymis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Orchitis
- Testicular torsion, trauma, or tumor
- Epididymal cyst
- Hydrocele
- Varicocele
- Spermatocele
- Testicular torsion should be considered in all cases (Table E1).

WORKUP

- Consideration of a full assessment of the urologic tract in patients with bacterial infection, especially if recurrent
- If discharge is present, cultures and Gram stain smear of urethral exudate. Gram stain should demonstrate ≥5 WBC per oil immersion field
- In sexually active men: Gonococcal cultures of the throat and rectum possibly of value
- If testicular torsion a consideration: Radionuclear imaging
- Examination of first void uncentrifuged urine for leukocytes if the urethral Gram stain is negative. Positive leukocyte esterase test on first-void urine or microscopic examination of first-void urine sediment will demonstrate ≥10 WBC per high power field. A culture and Gram-stained smear of this urine specimen should be obtained along with nucleic acid amplification testing (NAAT) from urine samples for gonorrhea and chlamydia
- Imaging with sonogram (Fig. E1)

LABORATORY TESTS

- All suspected cases of acute epididymitis should be tested for *C. trachomatis* and for *N. gonorrhoeae* by NAAT. Urine is the preferred specimen for NAAT testing.
- Urinalysis and urine culture if dysuria is present or if urinary tract infection is suspected.
- HIV testing and counseling.
- PPD placed and chest x-ray viewed if TB suspected (rare cases).
- Rarely, biopsy to ensure the diagnosis of tuberculous epididymitis.

TREATMENT

ACUTE GENERAL Rx

- Ice packs and scrotal elevation for relief of pain
- Analgesia with acetaminophen with or without codeine or NSAIDs
- Antibiotics to cover suspected pathogens. Empiric therapy is indicated before laboratory test results are available
- Recommended regimens are ceftriaxone 250 mg IM in a single dose plus doxycycline 100 mg bid for 10 days. For acute epididymitis most likely caused by enteric organisms, treatment options are levofloxacin 500 mg qd × 10 days or ofloxacin 300 mg bid × 10 days. Add ceftriaxone 250 mg IM single dose to levofloxacin or ofloxacin in men who practice insertive anal sex and are suspected to have chlamydia and gonorrhea and enteric organisms
- Best treatment for older men with gram-negative bacteriuria: Ofloxacin 300 mg PO bid for 10 days or levofloxacin 500 mg PO qd for 10 days
- *Pseudomonas* covered by ciprofloxacin PO or IV or cefepime (2 g IV q8h)
- Consider ampicillin-sulbactam, third-generation cephalosporin, ticarcillin-clavulanate, or piperacillin-tazobactam in toxic-appearing patients
- Surgical aspiration of local abscesses or even open surgical drainage
- Diabetics: Especially prone to develop more extensive scrotal infections, including Fournier gangrene
- Reinforcement of compliance with antibiotics to avoid partial treatment

CHRONIC Rx

- Repair of underlying structural defects is considered especially if infections are severe or recur.
- Surgical repair of reflux in young boys should be undertaken promptly and at a young age when possible.
- Sex partners of patient should be referred for evaluation and treatment.

REFERRAL

- If abscess or chronic structural problems suspected
- If another diagnosis, such as testicular torsion, is suspected

PEARLS & CONSIDERATIONS

- Recurrent epididymitis in sexually active men is usually related to failure to simultaneously treat sexual partners for STDs.
- Recurrent epididymitis in nonsexually active men is generally related to structural-anatomic defects in the genitourinary system or relapsing disease from inadequate initial treatment or antimicrobial resistance.
- Tuberculous epididymitis fails to respond to seemingly adequate antimicrobial therapy even without characteristic radiographic changes on chest films.

AUTHORS: **Philip A. Chan, MD, MS,** and **Glenn G. Fort, MD, MPH**

TABLE E1 Differentiation among Causes of the Acute Scrotum

Feature	Testicular Torsion	Appendix Torsion	Epididymitis
Age	<1 yr, puberty	7-14 yr	Adult
Onset	Hours	1-2 days	Days to weeks
Location of pain	Entire testicle	Upper pole	Epididymis
Systemic symptoms	Nausea	None	Fever
Cremasteric reflex	No	Intact	Intact
Pyuria	Rare	No	Yes
Ultrasound findings	Diffusely hypoechoic Asymmetrical testicles Normal or decreased flow Spermatic cord knot	Focally hypoechoic Symmetrical testicles Normal flow	Hypoechoic epididymis Symmetrical testicles Increased flow
Treatment	Surgery	Supportive	Antibiotics; prepuberty: Supportive only

NOTE: No single finding in patients with an acute scrotum can reliably differentiate torsion from other causative disorders. When torsion is a diagnostic possibility, prompt urology consultation is mandatory.

From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, Saunders.

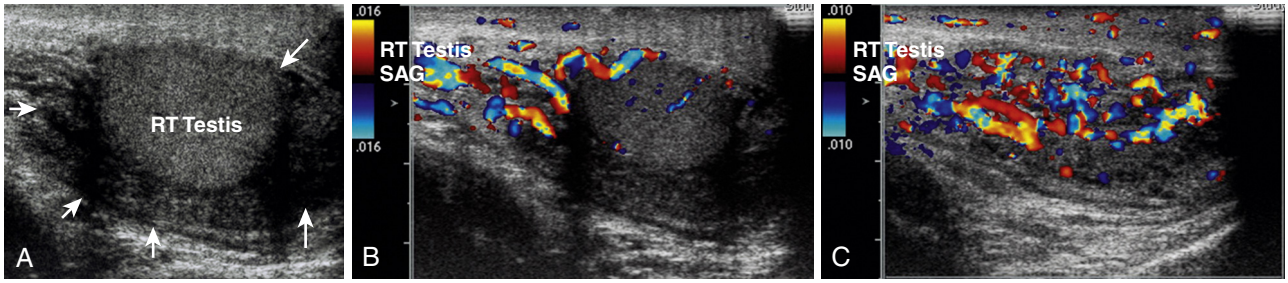

FIG. E1 Acute epididymitis in 8-year-old boy with right scrotal pain. A, Gray-scale sagittal sonogram of the right testis shows a normal-appearing testis surrounded posterolaterally by a prominent, hypoechoic heterogeneous epididymis. **B,** Longitudinal color flow Doppler image of the scrotum reveals increased flow in the head of the epididymis with normal flow in the testis. **C,** Marked hypervascularity is noted throughout the body and tail of the epididymis. Skin thickening is noted on all three images. (From Rumack CM et al: *Diagnostic ultrasound*, ed 4, Philadelphia, 2011, Elsevier.)

BASIC INFORMATION

DEFINITION

Epidural abscess is a suppurative infection of the central nervous system localized between the dura mater and the overlying skull or vertebral column. There are two types of epidural abscess: spinal epidural abscess (SEA) and intracranial epidural abscess (IEA), depending on the location within the central nervous system.

SYNONYMS

SEA
Spinal epidural abscess
IEA
Intraspinal abscess

ICD-10CM CODE
G06.2 Extradural and subdural abscess, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Spinal epidural abscess: 2 to 25 patients per 100,000 admissions; spinal epidural abscess is 9 times more common than intracranial abscess
PEAK INCIDENCE: Median age at onset of spinal epidural abscess: 50 yr old
PREVALENCE: Greatest between 50 and 70 yr of age
PREDOMINANT SEX: More common in men
RISK FACTORS: Bacteremia, secondary to distant infection; epidural catheter placement (0.5% to 3% risk), paraspinal injections of glucocorticoids or for pain management, contiguous bone or soft tissue infection, intravenous drug abuse, diabetes, immunosuppressive therapy, HIV

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Initially nonspecific, such as fever and malaise
- Classic triad: Fever, spinal pain, and neurologic deficits are not common
- More commonly:
  1. Localized and significant back pain is present.
  2. Nerve root pain is present ("shooting" or "electrical" from involved nerve root).
  3. Motor weakness, sensory changes, and even paralysis can occur.
  4. Fever may not be a prominent sign.

ETIOLOGY

- Bacteria enter the epidural space most often secondary to hematogenous spread from foci elsewhere in the body (25% to 50% of cases) or by direct extension from nearby infected tissues such as vertebral body or psoas muscle. A local intervention such as injection can also cause infection.
- Hematogenous foci include furuncles, cellulitis, urinary tract infection, pharyngitis, and pneumonia.
- Microbiology:
  1. *Staphylococcus aureus*, including methicillin-resistant S. *aureus* (MRSA), accounts for 50% to 90% of cases.
  2. Aerobic and anaerobic streptococci account for 8% to 17% of cases.
  3. Aerobic gram-negative rods *(Escherichia coli* and *Pseudomonas)* account for 10% to 17% of cases.
  4. Coagulase-negative staphylococci can be seen with spinal procedures.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Disc and degenerative bone disease
- Metastatic tumors
- Vertebral discitis and osteomyelitis

WORKUP

Includes a combination of physical exam with neurologic evaluation, blood work, and radiographic studies

LABORATORY TESTS

- Blood cultures
- Culture of fluid or pus for bacteria aerobically and anaerobically by CT-guided aspiration if possible. Fungal stain and cultures and AFB stain and culture should also be obtained to exclude more unusual pathogens.
- Erythrocyte sedimentation rate and/or C-reactive protein
- CBC with differential

IMAGING STUDIES

- MRI with gadolinium is the diagnostic test of choice (Fig. E1) and imperative if diagnosis is considered.
- CT is an alternative but not as good as MRI for visualizing spinal cord and epidural space.
- CT myelography can be performed if MRI is not available.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Immediate surgery is required if neurologic deficits occur or the patient worsens with medical therapy.
- CT-guided aspiration of abscess with antimicrobial therapy is an alternative treatment to surgery for patients without neurologic deficits.

ACUTE GENERAL Rx

- Empiric antibiotic regimen should include antibiotics effective against staphylococci (including MRSA), streptococci, and gram-negative rods.
- Examples are vancomycin: 30 to 60 mg/kg daily divided in q12h doses adjusted for creatinine clearance *plus* metronidazole (500 mg IV q8h) *plus* ceftriaxone (2 g IV q12h) or ceftazidime (2 g IV q8h) if *Pseudomonas* is suspected. Meropenem: 1 g IV q8h with vancomycin as an alternative, especially if penicillin allergic.
- If cultures reveal methicillin-sensitive *S. aureus*, use nafcillin 2 g IV q4h.

CHRONIC Rx

Antimicrobial therapy tailored to culture results may have to be continued for 4 to 6 weeks depending on whether or not there was surgical or CT-guided drainage. If osteomyelitis is suspected, treat for 6 to 8 weeks.

DISPOSITION

- Mortality rates vary from 5% to 32%. Irreversible paralysis can affect 4% to 22% of patients.
- Complete recovery is more likely if neurologic signs are present less than 24 hours before the start of treatment.
- Final functional capacity may continue to improve for up to 1 yr after the end of treatment.

REFERRAL

- Neurosurgery should be involved early when this diagnosis is considered.
- Refer to an interventional radiologist for possible aspiration.
- An infectious diseases evaluation is needed for antimicrobial therapy.

PEARLS & CONSIDERATIONS

COMMENTS

It is important to think of spinal epidural abscess early to permit early treatment and prevent permanent neurologic deficits.

Epidural Hematoma

BASIC INFORMATION

DEFINITION

Epidural hematoma (EDH) is the accumulation of blood in the potential space surrounding the brain, between the dura mater and the inner surface of the skull.

SYNONYMS

Extradural hematoma/hemorrhage
EDH

ICD-10CM CODES	
S06.4	Epidural hemorrhage
I62.1	Non-traumatic extradural hemorrhage
S06.4X0A	Epidural hemorrhage without loss of consciousness, initial encounter
S06.4X1A	Epidural hemorrhage with loss of consciousness of 30 minutes or less, initial encounter
S06.4X9A	Epidural hemorrhage with loss of consciousness of unspecified duration, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Exact incidence is unknown; however, it is found in 1% to 4% of traumatic head injury cases and 5% to 15% of autopsy series.
PREDOMINANT SEX AND AGE: Male > female
PEAK INCIDENCE: Peak incidence is among adolescents and young adults. It is rarely found in patients older than 50 to 60 yr old.
GENETICS: There is a role for genetics in spontaneous (nontraumatic) EDH caused by coagulopathies and vascular malformations.
RISK FACTORS: Head trauma, especially in cases involving skull fracture

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History of head trauma is present.
- Signs and symptoms vary depending on severity.
- Symptoms: Altered mental status, nuchal rigidity, headache, vomiting, drowsiness, confusion, aphasia, photophobia, and paralysis.
- Signs: Transient loss of consciousness, followed by a "lucid interval" in 47% of cases, in which the patient is free of any neurologic signs or symptoms. This is followed by clinical deterioration including vomiting, lethargy, confusion, or seizures. Other signs may include focal neurologic deficits such as paralysis of limbs, unequal pupils, and coma. Signs of increased intracranial pressure could be found including the Cushing reflex of hypertension, bradycardia, and respiratory distress. External signs of skull fracture—lacerations, ecchymoses, cerebrospinal fluid (CSF) rhinorrhea or otorrhea—may be observed. Skull fractures can be found in 75% to 95% of EDH patients.
- Coma or stupor with ipsilateral cranial nerve III palsy and contralateral hemiparesis may indicate transtentorial (uncal) herniation.

ETIOLOGY

- Traumatic: Commonly caused by arterial injury (the middle meningeal artery) from a temporal bone fracture (Fig. 1) but may also be injury of the anterior meningeal artery, a dural arteriovenous (AV) fistula at the vertex, or from venous bleeding
- Nontraumatic: Caused by an infection/eroding abscess, coagulopathy, hemorrhagic tumors, vascular malformations, postsurgical procedures, and in special populations (e.g., pregnant women, patients receiving hemodialysis)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

In the setting of head trauma: Subdural hematoma, subarachnoid hemorrhage, cerebral contusion, brain laceration, diffuse brain swelling

WORKUP

- Imaging is the mainstay of diagnosis.
- Serial head CT is the test most commonly used due to its simplicity, widespread use, and availability. Typical appearance is a "lens shaped," or "lentiform" hyperdensity (Fig. 2). Box 1 describes CT findings of EDH.
- Note: Head CT is not conclusive in 8% of cases possibly due to severe anemia, early scanning (before blood has time to accumulate), and severe hypotension.
- Brain MRI: More sensitive. Indicated in situations in which there is a strong clinical suspicion but no evidence of EDH on head CT (Fig. 3).
- Angiography: Rarely necessary but may be used to evaluate an underlying vascular lesion.
- NOTE: Lumbar puncture (LP) is contraindicated in EDH due to risk of brain stem herniation.

LABORATORY TESTS

- Laboratory tests are helpful as adjunct to diagnosis but are not the mainstay of diagnosis or treatment.
- CBC may be helpful to evaluate for anemia, although in an acute onset of bleeding hemoglobin levels can be normal.
- Other tests: Renal functions, electrolytes, liver functions, INR may be helpful depending on the case scenario.

TREATMENT

Acute symptomatic EDH is a neurologic emergency that requires surgical treatment to prevent permanent brain injury.

NONPHARMACOLOGIC THERAPY

- Immediate surgical decompression, ideally within 1 to 2 hr after traumatic event

FIG. 2 Head computed tomography showing two epidural hematomas in a 23-year-old involved in a motor vehicle accident. Note air bubbles that are a result of linear fracture in the left temporal bone *(short arrow).*

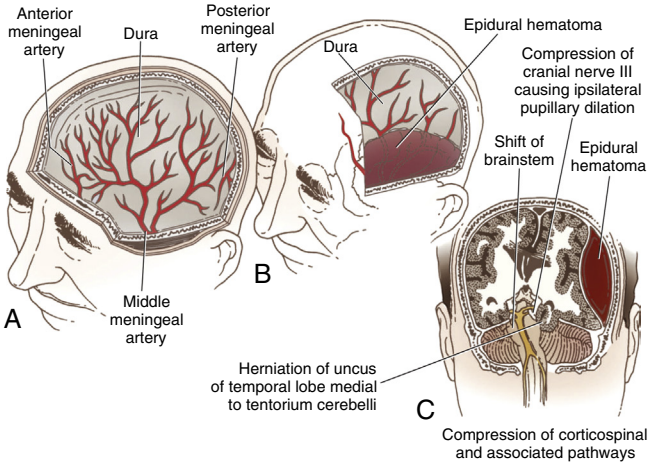

FIG. 1 Epidural hematoma is typically caused by trauma resulting in laceration of the middle meningeal artery. A, The middle meningeal artery. The typical traumatic epidural hematoma is caused by a laceration of this vessel. **B** and **C,** A linear fracture of the squamous portion of the temporal bone has torn the middle meningeal artery, which has resulted in an epidural hematoma. (From Rothrock JC: Neurosurgery. In Rothrock JC [ed.]: *Alexander's care of the patient in surgery,* ed 13, Philadelphia, 2007, Elsevier.)

BOX 1 Computed Tomography (CT) Findings of Epidural Hematoma

- CT appearance: variable white to gray on brain windows
- Location: peripheral to brain, variable but usually temporal region
- Shape: biconvex disc or lens
- Pearl: does not cross suture lines
- White swirl sign means active bleeding
- Significance: may cause mass effect and herniation
- Look for midline shift
- Look for effacement of ventricles and sulci
- Surgical indications: 15-mm thickness or 5-mm midline shift

From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.

FIG. 3 Epidural hematoma on magnetic resonance image. Coronal T2-weighted images show hypointense biconvex extraaxial collection in the left temporal region.

- Craniotomy and hematoma evacuation is the treatment of choice. When indicated, identify and ligate the bleeding vessel.
- Burr hole evacuation: This involves drilling a hole in the skull to evacuate the hematoma. It is a lifesaving procedure that is indicated if surgical expertise is limited.

ACUTE GENERAL Rx

- Cardiopulmonary resuscitation and assessment for disability.
- Medical resuscitation maneuvers: Head elevation, hyperventilation, monitoring of vital signs and avoidance of hypotension and hyperthermia, sedation if necessary.
- Medications: Osmotic diuresis with IV mannitol, cerebrosedating medications, antiepileptics may be used to treat or, in some situations, prevent seizures. The patient should also be started on a proton pump inhibitor to decrease risks of developing an upper gastrointestinal bleed.
- Reversing anticoagulation should be weighed in terms of advantages versus disadvantages.
- NOTE: Glucocorticoid therapy is *not* indicated following head injury and may be related to increased mortality.
- Evaluation for surgery: The best available evidence points toward advantages of decompression procedures. Nonoperative treatment may only be indicated if the patient has no symptoms, no focal neurologic deficit, no coma (Glasgow coma score >8), and EDH volume is less than 30 ml by CT scan, with clot thickness <15 mm and midline shift of less than 5 mm.
- Nonoperative treatment involves close monitoring, hourly neurologic checks, and serial head CT scans.

CHRONIC Rx

- There is a risk of permanent brain damage whether the disorder is treated or not. Most recovery occurs in the first 6 months with some improvement over 2 yr.
- Children have a tendency to recover more quickly.
- Patients should be educated on rehabilitative exercises and to alert medical professionals in the event of new neurologic symptoms.
- Support and encouragement to patient and family should always be provided.

REFERRAL

Neurosurgery should be the first service consulted. If not available, then general surgery needs to be called. Clinical nurse practitioners, pastoral care staff, and social workers to help patients and families are also appropriate.

PEARLS & CONSIDERATIONS

- Acute symptomatic EDH is a neurologic emergency. Urgent surgical evacuation is necessary in patients with Glasgow coma score less than 9, hematoma greater than 30 ml in volume, or presence of anisocoria.
- EDH should be suspected in any patient with a history of blow to the head leading to a period of loss of consciousness.
- Initial resuscitation is extremely important, but surgery is the mainstay of treatment for acute symptomatic EDH.

PREVENTION

Should be directed toward preventing head trauma: Use of appropriate safety equipment (e.g., helmets, hard hats, safe driving, avoiding diving into unknown depths)

PATIENT & FAMILY EDUCATION

Online head injury support groups are helpful: www.headinjury.com/linktbisup.htm, www.headinjury.com/, www.dailystrengthorg/c/Brain-Injury/support-group.

AUTHOR: **Fred F. Ferri, MD**

Epiglottitis PTG ALG

BASIC INFORMATION

DEFINITION

Epiglottitis is a rapidly progressive cellulitis of the epiglottis and adjacent soft tissue structures with the potential to cause abrupt airway obstruction, which can be life-threatening.

SYNONYMS

Supraglottitis
Cherry-red epiglottitis

ICD-10CM CODE
J05.1 Acute epiglottitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Due to vaccination against *Haemophilus influenzae* type B, this is a rare infection in children estimated at between 0.6 to 0.8 per 100,000 in one study and for adults at 1.6 per 100,000.
PEAK INCIDENCE: Now highest in children ages 6 to 12
PREDOMINANT SEX: Males

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Irritability, fever, dysphonia, and dysphagia
- Respiratory distress, with child tending to lean up and forward
- Often, drooling or oral secretions
- Often, presence of tachycardia and tachypnea
- On visualization, edematous and cherry-red epiglottis
- Often, no classic barking cough as seen in croup
- Possibly fulminant course (especially in children), leading to complete airway obstruction

ETIOLOGY

- In children, *Haemophilus influenzae* type b, still most common cause but now rare due to vaccination, *Streptococcus pyogenes,* (group A Streptococcus) *Streptococcus pneumoniae, and Staphylococcus aureus* (includes MRSA).
- In adults, *Streptococcus pyogenes* (group A Streptococcus), *H. influenzae* (can be isolated from blood and/or epiglottis [about 26% of cases]).
- Pneumococci, streptococci, and staphylococci are also implicated.
- Role of viruses in epiglottitis unclear.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Croup (Table E1)
- Angioedema
- Retropharyngeal or peritonsillar abscess
- Diphtheria
- Foreign body aspiration
- Lingual tonsillitis
- Bacterial tracheitis

WORKUP

- Cultures of blood and urine.
- Lateral neck radiograph to show an enlarged epiglottis, ballooning of the hypopharynx, and normal subglottic structures (Fig. 1).
  1. Radiographs are of only moderate sensitivity and specificity and take time to perform.
  2. Visualization of the epiglottis may be safer in adults than in children.
- Cultures of the epiglottis.

LABORATORY TESTS

- CBC: May reveal a leukocytosis with a shift to the left.
- Chest radiograph examination: May reveal evidence of pneumonia in close to 25% of cases.
- Cultures of blood, urine, and the epiglottis, as noted previously.

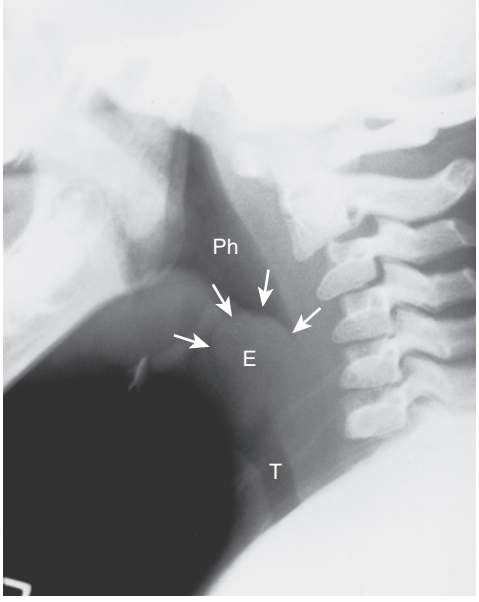

FIG. 1 Epiglottitis. A lateral soft tissue view of the neck shows a ballooned pharynx *(Ph)* with swollen epiglottis *(E)* in the shape of a large thumbprint *(arrows). T,* Trachea. (From Mettler FA [ed]: *Primary care radiology,* Philadelphia, 2000, Saunders.)

TREATMENT

ACUTE GENERAL Rx

- Maintenance of adequate airway is critical. Fig. E2 describes the optimal assessment and management of upper airway obstruction caused by epiglottitis or severe croup. It is crucial to have a tracheostomy set "at bedside."
- Early placement of an endotracheal or nasotracheal tube in a child is advised.
- Closely follow the adult patient, if no signs of airway obstruction, and defer intubation.
- In children, visualization and intubation are best done in the most controlled environment.
- *H. influenzae* in children is much less common in large part due to the HIB vaccine.

Empiric antibiotics:

- **In children:** Use cefotaxime 50 mg/kg IV q8h or ceftriaxone 50 mg/kg IV q24h *plus* vancomycin for its coverage of MRSA. If penicillin allergy, use levofloxacin 10 mg/kg IV q24h *plus* clindamycin 7.5 mg/kg IV q6h.
- **In adults:** Ceftriaxone 2 g IV q24h or cefotaxime *plus* vancomycin.
- If possible, obtain cultures before initiating antibiotics.
- If there is an unvaccinated child for *H. influenzae* at home (or in a day care center) who is >4 yr and living with an index case, give close family contacts of the patient (including adults) rifampin 20 mg/kg/day for 4 days (up to 600 mg/day) for prophylaxis.
- Role of epinephrine or corticosteroids in the management of epiglottitis is not firmly established.

DISPOSITION

Invasive *H. influenzae* infections and epiglottitis are reportable illnesses; this may be particularly important in recognizing an outbreak in a day care center with unvaccinated children.

REFERRAL

- Close cooperation between the pediatrician or internist, anesthesiologist, and otorhinolaryngologist, especially when epiglottis is visualized and when the patient requires endotracheal intubation.
- Best managed in a critical care setting or ICU.

PEARLS & CONSIDERATIONS

The incidence of epiglottitis has diminished markedly since the introduction of the protein conjugate vaccine against *H. influenzae* serotype B into routine childhood immunization.

The mortality rate now in children is about 1% but still remains at about 7% in adults.

BASIC INFORMATION

DEFINITION

Epiploic appendagitis is an ischemic infarction of an epiploic appendage caused by the torsion or spontaneous thrombosis of the epiploic appendage central draining vein. Epiploic appendages are fat-containing, peritoneum-bounded sites containing blood vessels that extend from the serosa of the colon. They vary in size from 5 mm to 5 cm and occur throughout the colon but are most numerous in the sigmoid colon. Epiploic appendagitis is usually a benign self-limited condition but can mimic other causes of acute abdomen such as diverticulitis or acute appendicitis.

SYNONYMS

Appendicitis epiploica
Epiplopericolitis
Hemorrhagic epiploitis
Appendagitis

ICD-10CM CODE
K55.0 Acute vascular disorders of the intestine

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Reported in 2% to 7% of patients suspected of diverticulitis and 0.3% to 1% of patients suspected of appendicitis
PEAK INCIDENCE: Reported age range of 12 to 82 yr with a peak incidence in the fifth decade of life
PREDOMINANT SEX AND AGE: Four times higher in men than women
RISK FACTORS: Obesity and strenuous exercise

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients present with acute or subacute onset of lower abdominal pain.
- Pain is left sided in 60% to 80% of cases and is nonmigratory, but worsens with cough and abdominal stretching.
- Less frequent are nausea and vomiting, low-grade fever, diarrhea, and bloating.
- Patients do not appear acutely ill, rebound tenderness is not common, and a mass is only palpable in 10% to 30% of patients.

ETIOLOGY

- Epiploic appendage: Small, fat-filled, serosa-covered sacs, attached on the external surface of the colon by vascular stalks, from cecum to rectosigmoid junction. There are about 50 to 100 of these, they measure 1 to 2 cm thick and 2 to 5 cm long, and they may serve as a protective and defensive mechanism
- Primary epiploic appendagitis: Ischemic infarction of an epiploic appendage either by torsion or spontaneous thrombosis of the epiploic appendage central draining vein, causing vascular occlusion and focal inflammation
- Secondary epiploic appendagitis: Inflammation of the epiploic appendage is caused by an external process such as diverticulitis, appendicitis, pancreatitis, or cholecystitis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Diverticulitis
- Ovarian torsion, ovarian cyst rupture, ectopic pregnancy
- Secondary epiploic appendagitis: Pancreatitis, and cholecystitis are predisposing conditions

WORKUP

- Physical exam, bloodwork, and radiology

LABORATORY TESTS

Complete blood count, erythrocyte sedimentation rate, C-reactive may be normal or mildly elevated

IMAGING STUDIES

- Abdominal CT: Characteristic finding of round or ovoid lesions of fatty density measuring 1.5 to 3 cm in diameter with a hyperattenuating rim (Fig. E1) and ill-defined fat stranding are seen in mesenteric fat adjacent to the colon. At times the thrombosed vein can be seen as a high attenuated dot within the appendage.
- Abdominal ultrasound: At the site of maximum tenderness, a noncompressible hyperechoic small ovoid or round solid mass of adipose tissue is identified between the colon and abdominal wall.

TREATMENT

PHARMACOLOGIC THERAPY

- Ibuprofen: 600 mg PO q8h for 4 to 6 days
- Opiates for pain for 4 to 6 days if needed

ACUTE GENERAL Rx

Epiploic appendagitis is usually a self-limited, benign condition lasting 3 to 14 days.

DISPOSITION

- Patients usually do not require hospitalization or antibiotics.
- Recurrence rates are low.

REFERRAL

Surgery is only required for patients who do not improve or who have a complication such as abscess or bowel obstruction.

PEARLS & CONSIDERATIONS

- It is important to consider this entity in patients with abdominal pain because the correct diagnosis could avoid unnecessary use of further diagnostic studies, antibiotic therapy, and even surgical therapy.
- Although symptoms of epiploic appendagitis generally resolve within 2 weeks, CT findings may persist for 6 months.

RELATED TOPICS

Appendicitis (Related Key Topic)
Diverticular Disease (Diverticulosis, Diverticulitis, Diverticular Hemorrhage) (Related Key Topic)

AUTHOR: **Glenn G. Fort, MD, MPH**

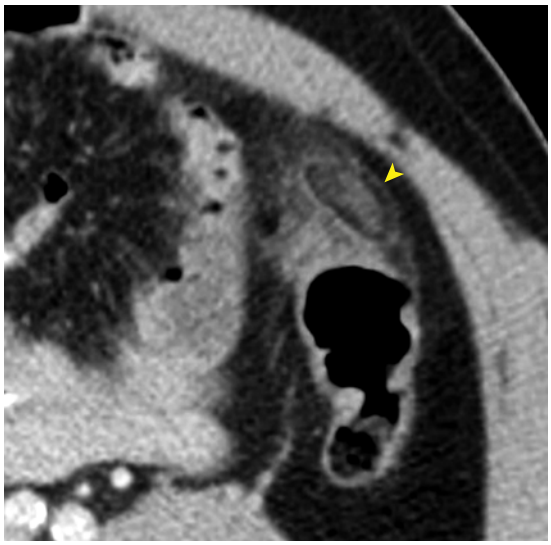

FIG. E1 Epiploic appendagitis. Axial computed tomography shows a pericolonic focus of inflammation enveloping a focus of fat *(arrowhead)*. This finding is characteristic of epiploic appendagitis. (From Webb WR, et al.: *Fundamentals of body CT,* ed 4, Philadelphia, 2015, Saunders.)

Episcleritis PTG

BASIC INFORMATION

DEFINITION

Episcleritis is an inflammation of the episclera, the thin layer of vascular elastic tissue between the sclera and conjunctiva.

ICD-10CM CODE
H15.1 Episcleritis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Relatively rare in an ophthalmologic practice
PEAK INCIDENCE: Most common in middle and old age
PREDOMINANT SEX: None
PREDOMINANT AGE: 40s

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Red, vascular injection of conjunctiva with engorged and enlarged blood vessels beneath the conjunctiva (Fig. E1)
- Pain in area of inflammation that is usually localized (severe pain suggests deeper inflammation; see Scleritis)
- Can be diffuse or nodular inflammation

ETIOLOGY

Associated with collagen-vascular diseases, vasculitis, trauma; usually idiopathic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute glaucoma.
- Conjunctivitis and blepharoconjunctivitis.
- Scleritis.
- Subconjunctival hemorrhage.
- Congenital or lymphoid masses.
- The differential diagnosis of "red eye" is described in Section II.
- Table E1 compares immunologic diseases of the eye.

WORKUP

Eye examination, general check-up for collagen-vascular disease or other autoimmune diseases

LABORATORY TESTS

Studies for collagen-vascular disease (e.g., antinuclear antibody, erythrocyte sedimentation rate, rheumatoid factor)

TREATMENT

NONPHARMACOLOGIC THERAPY

Warm compresses

ACUTE GENERAL Rx

- Topical steroids, 1% prednisolone if no glaucoma; nonsteroidal eye drops if there is a tendency for glaucoma.
- Nonsteroidal antiinflammatory drugs (NSAIDs): Treat underlying systemic disease.

CHRONIC Rx

NSAID eye drops (diclofenac eye drops, ketorolac ophthalmic solution)

DISPOSITION

Close follow-up needed

REFERRAL

To ophthalmologist if patient unresponsive to treatment after a few days

PEARLS & CONSIDERATIONS

COMMENTS

- Can rarely be associated with collagen-vascular disease.
- Episcleritis has a tendency to recur.
- May occur with systemic autoimmune disease. Workup for autoimmune disease is often negative, more likely with scleritis (50%). Ask about other symptoms to find autoimmune disorders, helps to guide workups.
- Episcleritis is a benign and self-limiting condition; loss of vision only occurs with steroid-induced cataracts. Prolonged topical steroid treatment is worse than the condition itself.

BASIC INFORMATION

DEFINITION

Epistaxis is defined as bleeding from the nose or nasal hemorrhage and is classified as either anterior or posterior.

SYNONYM

Nosebleed

ICD-10CM CODE
R04.0 Epistaxis

EPIDEMIOLOGY & DEMOGRAPHICS

- Epistaxis accounts for one of every 200 emergency department visits in the U.S. annually.
- It increases in frequency after age 20 yr and reaches the highest levels among the elderly population.
- More than 80% of cases of epistaxis are anterior in origin (Little area) and occur from Kiesselbach plexus.
- Only 5% of patients with epistaxis have posterior bleeds.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Nosebleed
- Hypotension and hemodynamic instability with acute, severe epistaxis

ETIOLOGY

- Approximately 90% of epistaxis events are idiopathic.
- Common identifiable causes are:
  1. Cold, dry environment
  2. Trauma (nose picking, accidents, and physical altercations)
  3. Structural deformities (septal deviations or spurs, chronic perforations)
  4. Inflammatory (rhinosinusitis, nasal polyposis)
  5. Allergies
  6. Foreign bodies in the nasal cavity
  7. Tumors (juvenile angiofibroma)
  8. Irritants
  9. Hypertension
  10. Coagulopathy (hemophilia, von Willebrand disease, thrombocytopenia)
  11. Osler-Weber-Rendu disease
  12. Renal failure
  13. Drugs: Aspirin, nonsteroidal antiinflammatory drugs, warfarin, alcohol, sildenafil, and tadalafil
  14. Blood vessel disorders (connective tissue disease, hereditary hemorrhagic telangiectasia)
  15. Pseudoaneurysm and aneurysm of the internal carotid artery might present as epistaxis

DIAGNOSIS

A good attempt should be made to directly visualize the source of bleeding to confirm the diagnosis and determine the best treatment. Fig. E1 illustrates anatomical sites for epistaxis.

DIFFERENTIAL DIAGNOSIS

Pseudoepistaxis must be ruled out. Common extranasal sites of bleeding that can simulate epistaxis include:

- Pulmonary hemoptysis
- Bleeding esophageal varices
- Tumor bleeding from the pharynx, larynx, or trachea

WORKUP

The workup should include laboratory blood testing to exclude obvious causes. Type and cross in anticipation of transfusion if the bleeding is severe.

LABORATORY TESTS

- Hemoglobin and hematocrit
- Platelet count
- Blood urea nitrogen and creatinine
- Coagulation studies (prothrombin time and partial thromboplastin time)
- Type and crossmatching of blood products

IMAGING STUDIES

Radiographic studies are usually not helpful.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Digital compression or pinching of the lower soft cartilaginous part of the nose for 10 min is the method of choice.
- Use cotton or tissue plug.
- The patient should be sitting and leaning forward, breathing through the mouth, allowing blood to flow out of the nostrils as opposed to bending backward, which would allow the blood to flow down the throat.
- Application of cold compresses to the bridge of the nose to cause a vasoconstrictive effect; the patient may also suck on ice to achieve this effect.

ACUTE GENERAL Rx

Anterior epistaxis:

- Local vasoconstriction is performed by moistening a cotton pledget with either:
  1. 4% lidocaine with 1:1000 epinephrine
  2. 4% lidocaine with 1% phenylephrine (Neo-Synephrine)
  3. 4% lidocaine with 0.05% oxymetazoline (Afrin)

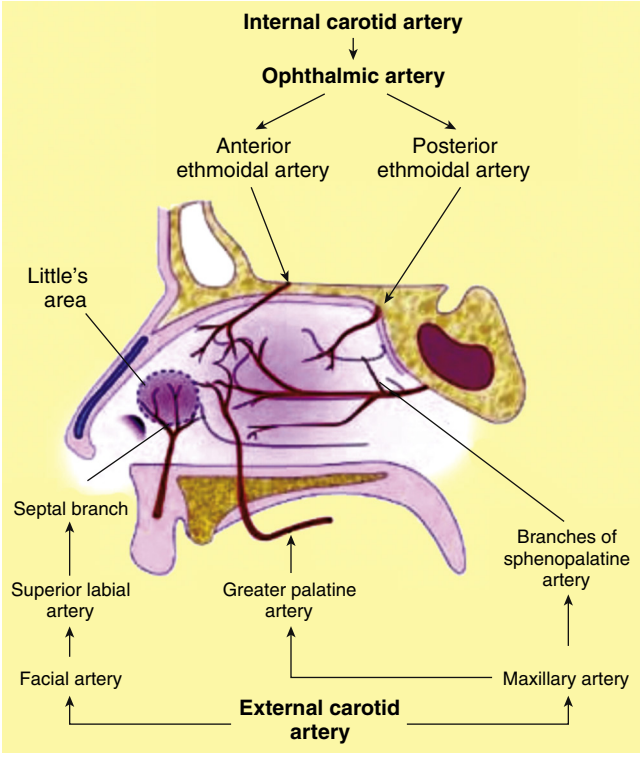

FIG. E1 Anatomical sites for epistaxis. (From McLarnon CM, Carrie S: Epistaxis, *Surgery (Oxford)* 30(11):584-589, 2012.)

4. 4% cocaine or cocaine 25% in paraffin base ointment and inserting the pledget into the nasal cavity with bayonet forceps
- Cauterization with silver nitrate or trichloroacetic acid is performed once hemostasis is achieved.
- Anterior nasal packing is needed when local measures are unsuccessful. Nasal packing is performed under local anesthesia and is done by inserting Vaseline gauze strips in layers from the floor of the nasal cavity to the front entrance of the nasal orifice. Enough pressure is placed to tamponade the epistaxis.
- Other commercially available nasal packing uses sponge packs that expand when exposed to blood or moisture and can be used for anterior epistaxis.

Posterior epistaxis:
- Posterior nasal packing:
  1. Commercially available nasal sponge packing can be applied
  2. Rolled gauze technique
- Foley catheter balloon insertion into the nasopharynx can be tried in patients with posterior epistaxis.

Newer agents in the treatment of epistaxis:
- Quick clot hemostatic agent, available OTC. When it comes in contact with blood in and around a wound, it absorbs the smaller water molecules from the blood to promote rapid clotting
- FloSeal hemostatic matrix, a combination of human thrombin, gelatin matrix, and calcium chloride, which are mixed together and placed at bleeding site
- Recombinant factor VIIa, generally reserved for uncontrolled epistaxis

CHRONIC Rx

- If acute treatment fails to stop the bleeding or the site of bleeding cannot be located, electrocautery or endoscopic cauterization can be used.
- Electrocautery is performed after suitable anesthesia, such as application of a topical anesthetic followed by local anesthetic injection. Only one side of the nasal septum should be cauterized at a time because perforation can result from bilateral cauterization.
- Arterial ligation or embolization has been used in refractory posterior epistaxis.
- For cases involving irritated or inflamed mucosa, a conservative regimen of triamcinolone 0.025%, Nemdyn, Nasalate, or equivalent cream should be applied once a week, combined with nightly application of a small quantity of petroleum jelly to the septum before bedtime.

DISPOSITION

- Most cases of anterior epistaxis from Kiesselbach plexus can be stopped by nasal compression and local vasoconstriction or cauterization.
- Nasal packing with gauze or sponge can control 90% of anterior epistaxis.
- Anterior and posterior packs are removed in 2 to 3 days. Hospital admission should be considered in patients who cannot be expected to return for prompt follow-up because prolonged packing increases the risk of pressure necrosis, toxic shock syndrome, sinus infections, and other complications.
- Although rare, epistaxis can lead to death by aspiration of blood, hemodynamic compromise from rapid excessive blood loss, or toxic shock syndrome.

REFERRAL

- If epistaxis cannot be controlled, an ear-nose-throat (ENT) specialist should be called for assistance.
- ENT specialist should be consulted in any patient with posterior epistaxis requiring posterior packing.

PEARLS & CONSIDERATIONS

COMMENTS

- Silver nitrate cauterization, if done on both sides of the nasal septum, can lead to septal perforation and should be discouraged.
- If anterior nasal packing is done, broad-spectrum antibiotics (e.g., amoxicillin-clavulanate 250 mg PO tid or trimethoprim-sulfamethoxazole 1 tablet PO bid) are used until the anterior packs are removed. Although it is customary to place patients on antibiotics to prevent sinusitis from obstruction, there is no proof that this is effective.
- Complications of nasal packing include:
  1. Aspiration
  2. Dislodged packing
  3. Infection
  4. Nasal trauma
- Traditional risk factors for epistaxis, including nasal perforation, nasal septum deviation, rhinitis, sinusitis, and upper respiratory tract infection, do not increase the risk of recurrent epistaxis. Significant risk factors for recurrent epistaxis include congestive heart failure, diabetes mellitus, hypertension, and a history of angina. Warfarin use also increases risk of recurrence, independent of INR. Aspirin and clopidogrel do not increase the risk of recurrent epistaxis.[1]

BASIC INFORMATION

DEFINITION

Epstein-Barr virus infection refers to a disease caused by Epstein-Barr virus (EBV), a human herpesvirus.

SYNONYMS

Infectious mononucleosis (IM)
Kissing disease

ICD-10CM CODES

B27.80	Other infectious mononucleosis without complication
B27.81	Other infectious mononucleosis with polyneuropathy
B27.82	Other infectious mononucleosis with meningitis
B27.89	Other infectious mononucleosis with other complication
B27.90	Infectious mononucleosis, unspecified without complication
B27.91	Infectious mononucleosis, unspecified with polyneuropathy
B27.92	Infectious mononucleosis, unspecified with meningitis
B27.99	Infectious mononucleosis, unspecified with other complication

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 5 cases/100,000 persons per yr of IM
PREDOMINANT SEX: Neither, although peak incidence occurs about 2 yr earlier in women
PREDOMINANT AGE:

- Clinical evidence of IM: Occurs most commonly at ages 15 to 24 yr
- EBV infection: Occurs earlier in life in lower socioeconomic groups

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most EBV infections either are asymptomatic or cause a nonspecific viral illness.
- Incubation period is 1 to 2 mo, possibly followed by a prodrome of anorexia, low-grade fever, malaise, headache, and chills; after several days, clinical triad of pharyngitis, moderate to high fever, and adenopathy may appear, accompanied by fatigue and malaise.
- Pharyngitis is usually the most severe symptom; white or necrotic exudates are common.
- Symmetrical lymphadenopathy is most prominent in the posterior more than anterior cervical region but may be diffuse.
- Splenomegaly (50% of cases) is possible, most commonly during the second week of illness.
- Maculopapular or morbilliform rash is uncommon but will often occur in patients who receive ampicillin (Fig. E1). Patients may have palatal petechiae, periorbital, or palpebral edema. Mucocutaneous oral hairy leukoplakia (OHL), which is associated with intense EBV replication and the action of EBV-encoded proteins such as latent membrane protein-1, may occur.
- Possible IM presentation: Fever and adenopathy without pharyngitis.
- Nausea, vomiting, and anorexia are frequent in patients with IM, probably reflecting mild hepatitis encountered in 90% of infected individuals.
- Although complications such as spleen rupture, airway obstruction, and malignancy may be severe and fatal, they are uncommon and tend to resolve completely.
- Hematologic involvement includes hemolytic or aplastic anemia, thrombocytopenia, thrombotic thrombocytopenic purpura/hemolytic-uremic syndrome, and disseminated intravascular coagulation (DIC). Pneumonia, myocarditis, pancreatitis, mesenteric adenitis, myositis, and glomerulonephritis may occur as well. Nervous system involvement includes Guillain-Barré syndrome, facial nerve palsy, meningoencephalitis, aseptic meningitis, transverse myelitis, peripheral neuritis, and optic neuritis.
- IM is usually a self-limited illness. Acute symptoms resolve in 1 to 2 wk, but symptoms of malaise and fatigue often persist for months.
- EBV is related to lymphoproliferative syndromes in transplant recipients and in AIDS patients.
- Increasing evidence showing an association between EBV infection and African Burkitt, B-cell or T-cell lymphoma, and nasopharyngeal carcinoma. Table 1 describes EBV-associated malignancies.

ETIOLOGY

- EBV is a ubiquitous virus.
- Infection during childhood is much less likely to cause significant illness.
- Frequency of IM in late adolescence is attributed to the onset of social contact between the sexes.
- Close personal contact is usually necessary for transmission, although EBV is occasionally transmitted by blood transfusion; transfer via saliva while kissing may be responsible for many cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Heterophile-negative IM caused by cytomegalovirus (CMV)
- Although clinical presentation similar, CMV more frequently follows transfusion
- Bacterial and viral causes of pharyngitis
- Toxoplasmosis
- Acute retroviral syndrome of HIV
- Lymphoma
- Lyme disease

WORKUP

Heterophile antibody and CBC with blood smear. Table 2 describes frequently determined EBV-specific antibodies.

LABORATORY TESTS

- Increased WBC common, with a relative lymphocytosis of more than 50% and neutropenia identified.
- Hallmark of IM: Atypical lymphocytes of more than 10% (not pathognomonic) are found.
- Mild thrombocytopenia is present.
- Falling hematocrit signals the possibility of splenic rupture or immune hemolytic anemia.
- Elevated hepatocellular enzymes and cryoglobulins are found in most cases.
- Heterophile antibody:
  1. As measured by the monospot test, may be positive at presentation or may appear later in the course of illness. Its accuracy is 71% to 90% but has a 25% false-negative rate in the first week of illness.
  2. A negative test should be repeated in 1 wk if clinical suspicion is high.
  3. A false-positive test has been reported with primary HIV infection.
- Viral capsid antigen (VCA) IgG and IgM are rarely used for diagnosis, but better value in children because heterophile antibody is negative in most children younger than 8 yr.

TABLE 1 Epstein-Barr Virus (EBV)-Associated Malignancies

Malignancy	EBV Frequency (%)
Hodgkin disease	~40
Non-Hodgkin lymphomas	
Burkitt lymphoma	20-95
Diffuse large B-cell lymphoma and CD30$^+$ Ki-1$^+$ anaplastic large cell lymphoma	10-35
Lymphomatoid granulomatosis	80-95
T-cell–rich B-cell lymphoma	20
Angioimmunoblastic lymphoma	>80
T-cell, NK-cell, and T/NK-cell lymphomas	30-90
Nasopharyngeal carcinoma	>95
Gastric adenocarcinoma	5-10
Pyothorax-associated lymphoma	>95
Leiomyosarcoma in immunocompromised patients	>95

NK cell, Natural killer cell; *T cell,* T lymphocyte cell.
From Hoffman R et al: *Hematology: basic principles and practice,* ed 5, Philadelphia, 2009, Churchill Livingstone.

TABLE 2 Frequently Determined EBV-Specific Antibodies

Antibody Specificity	Positive in IM (%)	Time of Appearance in IM	Persistence	Comments
Viral Capsid Antigen				
VCA-IgM	100	At clinical presentation	4-8 weeks	Highly sensitive and specific; of major diagnostic utility
VCA-IgG	100	At clinical presentation	Lifelong	Useful for documentation of past EBV infection
Early Antigen				
Anti-D	70	Peaks 3-4 weeks after onset	3-6 months	Correlates with disease severity; seen in NPC patients
Anti-R	Low	2 weeks to several months after onset	2 months to >3 yr	Occasionally seen with unusually severe cases; seen in African Burkitt lymphoma patients
EBNA	100	3-4 weeks after onset	Lifelong	Presence excludes primary EBV infection

EBNA, EBV nuclear antigen; *EBV,* Epstein-Barr virus; *Ig,* immunoglobulin; *IM,* infectious mononucleosis; *NPC,* nasopharyngeal carcinoma; *VCA,* viral capsid antigen.
Adapted from Schooley RT: Epstein-Barr virus (infectious mononucleosis). In Mandell GL et al (eds): *Principles and practice of infectious diseases,* Philadelphia, 2010, Churchill Livingstone.

- PCR DNA for CMV is the test of choice in transplant recipients who develop lymphoproliferative syndromes.

IMAGING STUDIES

Chest radiograph examination:
- May rarely show infiltrates
- Possible elevated left hemidiaphragm with splenic rupture

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive including rest
- Splenectomy if rupture occurs
- Transfusions for severe anemia or thrombocytopenia

ACUTE GENERAL Rx

- Pharmacologic therapy is not indicated in uncomplicated illness.
- Avoid aspirin due to the risk of Reye syndrome.
- Avoid ampicillin and amoxicillin as their use can frequently precipitate a nonallergic rash. Azithromycin has also been implicated.
- Use of steroids is suggested in patients who have severe thrombocytopenia, hemolytic anemia, impending airway obstruction resulting from enlarged tonsils, or fulminant liver failure. Prednisone 60 to 80 mg PO qd for 3 days, then tapered over 1 to 2 wk.
- Although it may reduce initial viral shedding, there is little evidence to support the use of antiviral agents such as acyclovir in the management of IM.

CHRONIC Rx

An extremely rare, chronic form of IM with persistent fevers and fatigue has been described and should be differentiated from chronic fatigue syndrome, which is not related to EBV.

DISPOSITION

Eventual resolution of all symptoms

REFERRAL

If more than mild illness

PEARLS & CONSIDERATIONS

- Epstein-Barr infection will occur in 95% of the world population at some point in life.
- It is felt the antibiotic-induced rash in IM is a transient virus-mediated immune alteration that sets the stage for loss of antigenic tolerance and the development of a reversible, delayed-type hypersensitivity reaction to the antibiotic

COMMENTS

Avoidance of contact sports during the first month of illness because splenic rupture can occur even in the absence of clinically detectable splenomegaly in 0.1% to 0.5% of patients.

BASIC INFORMATION

DEFINITION

Erectile dysfunction (ED) is the persistent inability to achieve or sustain a penile erection of adequate rigidity to make sexual penetration possible or satisfactory.

SYNONYMS

ED
Impotence
Male erectile disorder
Sexual dysfunction (a nonspecific term)

ICD-10CM CODES

N48.4	Impotence of organic origin
F52.2	Failure of genital response
F52.9	Unspecified sexual dysfunction, not caused by organic disorder or disease
N52.01	Erectile dysfunction due to arterial insufficiency
N52.02	Corporo-venous occlusive erectile dysfunction
N52.03	Combined arterial insufficiency and corporo-venous occlusive erectile dysfunction
N52.1	Erectile dysfunction due to diseases classified elsewhere
N52.2	Drug-induced erectile dysfunction
N52.31	Erectile dysfunction following radical prostatectomy
N52.32	Erectile dysfunction following radical cystectomy
N52.33	Erectile dysfunction following urethral surgery
N52.34	Erectile dysfunction following simple prostatectomy
N52.39	Other post-surgical erectile dysfunction
N52.8	Other male erectile dysfunction
N52.9	Male erectile dysfunction, unspecified

DSM-5 CODE

302.72	Failure of genital response

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (IN U.S.):

- Increases with age and presence of specific medical comorbidities
- Approximately 8% in the 20s to 30s, 18% in the 50s, 25% in the 60s, 37% in the 70s, 80% in the 80s

PREDOMINANT SEX: By definition, only in males

PREDOMINANT AGE: Increases with age

RISK FACTORS: Age, coronary artery disease, peripheral vascular disease, hypertension, hypogonadism, diabetes mellitus, hypercholesterolemia, prostate surgery, neurologic injury, numerous medications, alcohol, smoking or drug abuse, obesity, obstructive sleep apnea, systemic sclerosis; psychological: performance anxiety

ETIOLOGY

- A classification of male erectile dysfunction is described in Box 1.
- Most cases involving men older than 50 yr are caused by organic problems related to neurologic, hormonal, or vascular abnormalities or prescription or recreational drugs. In organic ED, nocturnal penile tumescence is generally diminished or absent, and ED is also experienced during private masturbation and across partners.
- Psychogenic ED results from mental stress, depression, a stressful partner relationship, a partner's sexual and mental health problems, and performance anxiety. Performance anxiety is extremely common and is characterized by a focus on the performance outcome of sex (i.e., obtaining and maintaining an erection) rather than a focus on the process and enjoyment of sex. Psychogenic ED is characterized by normal nocturnal penile tumescence and/or erections associated with erotic material or other partners, and by otherwise negative medical test results.
- Vascular disease: History of hypertension (HTN), peripheral vascular disease, ischemic heart disease, diabetes, smoking. In approximately 40% of men >50 yr, the primary cause of ED is related to atherosclerotic disease, diabetes mellitus (DM), neuropathy, or vascular disease.
- Obesity and metabolic syndrome.
- Medication side effects: Antihypertensives such as thiazides and clonidine, guanethidine or methyldopa (consider change to ACE inhibitors and calcium channel blockers with lower reported incidence of ED); antiandrogens such as spironolactone, finasteride, ketoconazole; cimetidine (but not ranitidine or famotidine); antidepressants such as selective serotonin reuptake inhibitors [SSRIs]; and antipsychotics. Table 1 summarizes drug-induced erectile dysfunction and suggested alternatives.

BOX 1 Classification of Male Erectile Dysfunction

Organic
- I. Vasculogenic
  - A. Arteriogenic
  - B. Cavernosal
  - C. Mixed
- II. Neurogenic
- III. Anatomic
- IV. Endocrinologic

Psychogenic
- I. Generalized
  - A. Generalized unresponsiveness
    1. Primary lack of sexual arousability
    2. Aging-related decline in sexual arousability
  - B. Generalized inhibition
    1. Chronic disorder of sexual intimacy
- II. Situational
  - A. Partner-related
    1. Lack of arousability in specific relationship
    2. Lack of arousability owing to sexual object preference
    3. High central inhibition owing to partner conflict or threat
  - B. Performance-related
    1. Associated with other sexual dysfunction (e.g., rapid ejaculation)
    2. Situational performance anxiety (e.g., fear of failure)
  - C. Psychological distress or adjustment related
    1. Associated with negative mood state (e.g., depression) or major life stress (e.g., death of partner)

From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.

TABLE 1 Drug-Induced Erectile Dysfunction and Suggested Alternatives

Class	Known to Cause Erectile Dysfunction	Suggested Alternatives
Antihypertensives	Thiazide diuretics General β blockers	α-Blockers Calcium channel blockers Specific β-blockers Angiotensin-converting enzyme inhibitors Angiotensin II receptor antagonists
Psychotropics	Antipsychotics Antidepressants Anxiolytics	Anxiolytic (buspirone); antidepressant (bupropion)
Antiandrogen	Androgen receptor antagonists Luteinizing hormone–releasing hormone agonists 5α-Reductase inhibitors	
Opiates		
Antiretroviral agents		
Tobacco		Quit smoking
Alcohol	Large amount	Small amount

From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.

- Excessive alcohol and nicotine use.
- Recreational drugs, including cocaine, heroin, amphetamines, and marijuana. These may increase libido but impair performance.
- Hormonal dysfunction such as testosterone deficiency (decreases libido and erection), hypothyroidism or hyperthyroidism, hyperprolactinemia, and adrenal insufficiency.
- Neurogenic causes including spinal cord lesions, cortical lesions, and peripheral neuropathies.
- Trauma or pelvic surgeries such as radical prostatectomy or cystectomy.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- A useful tool to diagnose/evaluate ED severity is the Sexual Health Inventory for Men (SHIM).
- Distinguish psychogenic and organic contributions to ED.
- Evaluate for underlying etiology of organic ED and comorbid psychiatric condition.

WORKUP

- Clinical history should include time course (abrupt onset may correlate with reversible cause such as medications, psychosocial stress, psychiatric complaint, trauma; nonsustained erection may be secondary to anxiety or vascular steal syndrome), cause (psychogenic vs. organic), and change in libido. Box 2 describes symptoms suggesting neurologic sexual impairment.
- Report of spontaneous nocturnal or morning erections indicate intact neurologic reflexes and penile blood flow.
- Decreased libido may indicate endocrinologic or psychogenic cause.
- If possible, interview partner regarding partner's sexual function, relationship satisfaction, and mental health history.
- Medical and social history should address cardiac disease symptoms and risk factors (HTN, DM, hyperlipidemia, smoking, and substance abuse), pelvic surgery, medications, and mental health. Coronary artery calcium score (CAC) is best indicator of subclinical coronary artery disease.

BOX 2 Symptoms Suggesting Neurologic Sexual Impairment

- Continual erectile dysfunction
  - Absence of morning erections
  - No erection or orgasm during masturbation or sex with different partners
- Related somatic complaints
- Sensory loss in genitals, pelvis, or legs
- Urinary incontinence
- Certain neurologic conditions
  - Spinal cord injury
  - Diabetic neuropathy
  - Multiple sclerosis
  - Herniated intervertebral disk
- Use of many medications

From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.

- Physical examination to check blood pressure, visual field defects to evaluate for pituitary tumors; femoral and peripheral pulses, femoral bruits; gynecomastia; neuronal damage (genital sensation, cremasteric reflex); direct penile damage (e.g., plaque formation such as Peyronie disease); prostate examination; or testicular atrophy and other secondary sexual characteristics. Signs of neurologic sexual impairment are summarized in Box 3.

LABORATORY TESTS

Screen for diabetes mellitus with fasting glucose. Consider lipid panel, thyroid-stimulating hormone, morning serum testosterone (free and total). If decreased testosterone, check prolactin, follicle-stimulating hormone, and luteinizing hormone.

IMAGING STUDIES

Imaging studies are rarely performed except in situations of pelvic trauma or surgery.

OTHER STUDIES

- Nocturnal penile tumescence testing is very specific for distinguishing psychogenic versus organic causes.
- Neurogenic etiologies examined by the cremasteric reflex (inner-thigh touch elicits scrotal contraction), the bulbocavernosus reflex, or the pudendal-evoked response.
- Intracorporeal injection of prostaglandin E_1 to distinguish vascular and nonvascular etiologies (erection is achieved in patients with normal vascular systems). If no erection with direct injection of vasoactive substance, consider duplex ultrasound of penile vasculature.
- In patients without an obvious cause of ED, consider screening for cardiovascular disease prior to starting treatment.

Rx TREATMENT (FIG. 1)

NONPHARMACOLOGIC THERAPY

- Various psychotherapeutic approaches: Cognitive-behavioral therapy preferred; success rates decrease with advancing age and duration of symptoms.

BOX 3 Signs of Neurologic Sexual Impairment

- Signs of spinal cord injury
  - Paraparesis or quadriparesis
  - Leg spasticity
  - Urinary incontinence
- Signs of autonomic nervous system injury
  - Orthostatic hypotension or lightheadedness
  - Anhidrosis in groin and legs
  - Urinary incontinence
  - Retrograde ejaculation
- Signs of peripheral nervous system injury
  - Loss of sensation in the genitals, "saddle area," and legs
  - Paresis and areflexia in legs
  - Scrotal, cremasteric, and anal reflex loss

From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.

- Psychosexual therapy is first line for psychogenic ED. Psychosexual therapy may be used as for adjunctive therapy in ED from any cause to address contributing, performance anxiety, social, and relationship issues.
- Performance anxiety is best addressed by sensate focus in which a couple is asked to refrain from sexual penetration but enjoy erotic touching.
- Mechanical vacuum devices (function by drawing blood into corpus cavernosum) are 70% to 90% effective but are difficult to use and subject to noncompliance.
- Incorporate vascular risk factor reduction including counsel on diet, exercise, smoking cessation, ETOH intake and screening/treatment for HTN, insulin resistance, and hypercholesterolemia as appropriate. Trials have shown that lifestyle modification and pharmacotherapy for cardiovascular risk factors are effective in improving sexual function in men with ED.

ACUTE GENERAL Rx

- First-line treatment: In setting of sexual stimulation, four selective phosphodiesterase type 5 (PDE5) inhibitors (Table 2) prolong nitric oxide–induced vasodilation by increase of intracavernosal cyclic guanosine monophosphate levels. Sildenafil (Viagra) and vardenafil (Levitra, Staxyn) can be taken 30 to 60 min before sexual activity, and both are effective for about 4 hr. Avanafil (Stendra) can be taken 15 to 30 min before sexual activity and is effective for about 6 hr. Tadalafil (Cialis) can be taken several hours before sexual activity (although 50% respond within 30 min) and lasts up to 36 hr. All four PDE5 inhibitors have similar efficacy and tolerability, but tadalafil has a longer duration of action and is less affected by high-fat meals and alcohol. Counsel patients to avoid high-fat meals and excessive alcohol when taking PDE5 inhibitors, as they may impede effectiveness.
- With PDE5 inhibitors, avoid concomitant use of nitrates (absolute contraindication), drugs that inhibit or induce cytochrome P450 CYP3A4, and drugs that prolong the QT interval. Caution in men on alpha-adrenergic blocker therapy because of concern for hypotension; start the lowest dose of PDE5 inhibitor. Caution in men who have had myocardial infarction in the past 6 mo, resting hypotension or uncontrolled hypertension, unstable angina, positive exercise stress test or poor exercise tolerance. Counsel on side effects of headache, flushing, dyspepsia, nasal congestion, changes in color perception (including blue vision for sildenafil and vardenafil but not tadalafil), sudden hearing loss, and priapism (rare). Nonarteritic anterior ischemic optic neuropathy is also a rare association with sildenafil and tadalafil. Consider counseling on safe sexual practices when prescribing PDE5 inhibitors.
- Second-line treatment if PDE5 inhibitors fail: Self-injection with intraurethral alprostadil (prostaglandin E_1 [medicated urethral suppository]) applied into meatus of penis before intercourse; or intracavernosal injections of vasodilators (e.g., papaverine or prostaglandin E_1). Consider combining intraurethral

alprostadil with PDE5 inhibitor. Relatively high success with self-injection, but attrition is high (Table E3).
- Second-line treatment alternative: Vacuum constriction pump; has variable satisfaction rate.

CHRONIC Rx

- Psychosexual therapy is helpful as an adjunctive treatment.
- Psychogenic impotence: PDE5 inhibitors are effective in patients with depression because tissues, nerves, hormones, and vasculature are normal. PDE5 inhibitors are also effective as a way of providing positive experiences and building sexual confidence. Full psychological evaluation is recommended before starting treatment.
- For men not responding to other approaches: Surgical implantation of penile prosthesis may be considered. Full psychological evaluation is recommended to evaluate the possibility of unrealistic expectations or partner problems contributing to ED.
- Testosterone therapy in men with low testosterone (i.e., hypogonadal); evaluate for prostate cancer before prescribing testosterone.
- Aerobic exercise may improve ED along with pharmacologic treatment.

DISPOSITION

- Psychogenic-acquired ED will remit spontaneously in 15% to 30% of cases.
- Lifelong ED is usually a chronic and unremitting condition.
- Situational ED may remit with changes in social environment and reducing performance anxiety.

REFERRAL

- Refer if psychotherapy, sexual focused therapy, or invasive organic treatment required
- Refer to urology if PDE5 inhibitors fail or sudden onset occurs after penile trauma

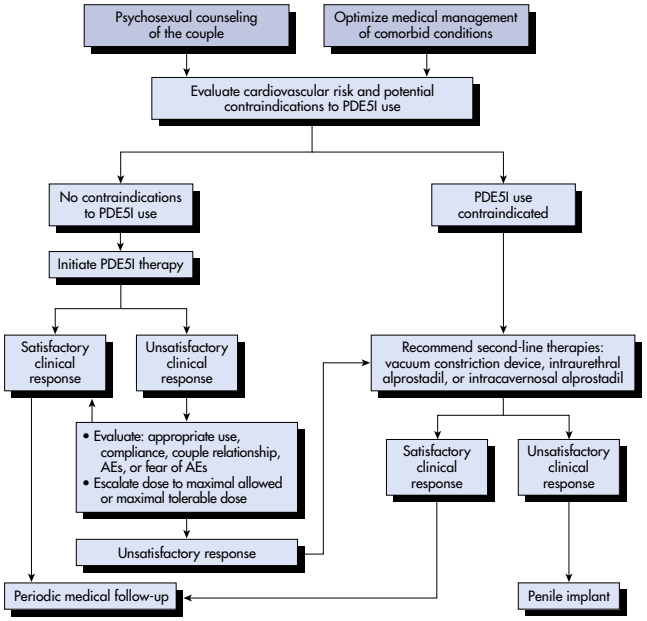

FIG. 1 An algorithmic approach to the treatment of erectile dysfunction in men. *AE,* Adverse effects; *PDE5I,* phosphodiesterase 5 inhibitor. (From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders.)

PEARLS & CONSIDERATIONS

- ED is commonly evaluated and treated by primary care physician; refer to urologist if oral therapy fails or surgery is required.
- PDE5 inhibitors are treatment of choice for most causes of ED. Main contraindications are nitrate use and decompensated cardiac disease. Caution in patients on alpha-adrenergic blockers and with blood pressures at extreme ends (significant hypotension or hypertension).
- For optimal response, patients should be appropriately informed of proper use, precautions, and adverse effects of PDE5 inhibitors. Try six to eight times at optimal doses before declaring PDE5 inhibitors a failure. Consider switching among the four PDE5 inhibitors if one fails.
- Men with ED are at increased risk of coronary, cerebrovascular, and peripheral vascular diseases. Screen for cardiovascular risk factors in these patients.

Wincze JP, Weisberg RB: *Sexual dysfunction: a guide for assessment and treatment*, ed 3, NY, 2015, Guilford Press.

TABLE E3 Guidelines for Intracavernosal Therapy

1. Do not prescribe intracavernosal therapy to men who have psychiatric disorders, hypercoagulable states, or sickle cell disease; who are receiving anticoagulant therapy; or who are unable to comprehend the risks or take appropriate action should complications occur.
2. Designate a physician or a urologist to be available to handle emergencies related to complications of intracavernosal injections, such as prolonged erection and priapism.
3. Instruct the patient in the injection technique, the risks of intracavernosal therapy, and the steps to be taken in the event of prolonged erection or priapism.
4. Administer the first injection in the office, and observe the blood pressure and heart rate response. This provides an excellent opportunity for educating the patient, observing adverse effects, and determining whether the patient will respond to intracavernosal therapy.
5. Start with a low dose of alprostadil and titrate the dose based on the erectile response and the duration of erection. Adjust the dose of alprostadil to achieve an erection that is sufficient for sexual intercourse but does not last more than 30 min.
6. If the erection does not abate in 30 min, the patient should be instructed to take a tablet of pseudoephedrine or terbutaline (Brethine) or an intracavernosal injection of phenylephrine. If this is not effective, the patient should call the designated physician or urologist and go to the emergency department.

From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders, Elsevier.

Erysipelas PTG

BASIC INFORMATION

DEFINITION

Erysipelas is a type of cellulitis caused by infection of the superficial layers of the skin and cutaneous lymphatics. Erysipelas is characterized by redness, induration, lymphangitis, lymphadenopathy, and a sharply demarcated, raised border.

SYNONYM

St. Anthony's fire

ICD-10CM CODE
A46 Erysipelas

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT AGE: Occurs most often in the young or old
RISK FACTORS: Patients with impaired lymphatic or venous drainage (mastectomy, saphenous vein harvesting) and immunocompromised patients. Athlete's foot is a common portal of entry.
RECURRENCE RATE: Relatively common

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Distinctive red, warm, tender skin lesion with induration and a sharply defined, advancing, raised border (Fig. E1).
- Most common sites are lower extremities and face.
- Systemic signs of infection (fever) are often present.
- Vesicles or bullae may develop.
- After several days, lesions may appear ecchymotic.
- After 7 to 10 days, desquamation of affected area may occur.

ETIOLOGY

- Usually group A β-hemolytic streptococci (GABHS)
- Less often group B, C, or G streptococci
- Rarely *Staphylococcus aureus*

COMPLICATIONS

- Abscess
- Necrotizing fasciitis
- Thrombophlebitis
- Gangrene
- Metastatic infection

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other types of cellulitis
- Necrotizing fasciitis
- Deep vein thrombosis
- Stasis dermatitis
- Erythema nodosum
- Contact dermatitis
- Erythema migrans (Lyme disease)
- Insect bite
- Herpes zoster
- Erysipeloid
- Acute gout
- Pseudogout

WORKUP

History, physical examination, and laboratory evaluation

LABORATORY TESTS

Diagnosis is usually made by characteristic clinical setting and appearance.

- Complete blood count: White blood cell count often elevated
- Blood cultures positive in 5% of patients. Septic, or there is a history of animal bites for immersion injury and are not routinely indicated unless the host is immunocompromised
- Gram stain and culture of any drainage from skin lesions has low yield
- Culture of aspirated fluid from leading edge of skin lesion has low yield

IMAGING STUDIES

- Not routinely indicated
- Duplex ultrasound for patients suspected of having deep vein thrombosis
- CT scan or MRI for patients with suspected necrotizing fasciitis

TREATMENT

NONPHARMACOLOGIC THERAPY

- Elevation of the affected limb
- Warm compresses

ACUTE GENERAL Rx

Typical erysipelas of extremity in nondiabetic patient:

- PO: Penicillin V 500 mg q6h. Use clindamycin in patients who are allergic to penicillin.
- IV: Penicillin G (aqueous) 1 to 2 million units q6h. Use vancomycin 15 mg/kg IV q12h in penicillin-allergic patients.

Facial erysipelas (include coverage for *Staphylococcus aureus*):

- PO dicloxacillin 500 mg q6h
- IV nafcillin or oxacillin 2 g q4h
- IV vancomycin 1 g q12h
- Daptomycin 4 mg/kg IV q24h
- Linezolid 600 mg IV q12h

DISPOSITION

Prognosis is good with antibiotic treatment but recurrence is common.

REFERRAL

For surgical debridement for patients with necrotizing fasciitis or for drainage of abscess

PEARLS & CONSIDERATIONS

- Consider early surgical referral when necrotizing fasciitis suspected. Consider skin biopsy when not responding to appropriate antibiotics.
- Look for tinea pedis as portal of entry in erysipelas of lower extremities, and treat if present.

Erythema Elevatum Diutinum

BASIC INFORMATION

DEFINITION

Erythema elevatum diutinum (EED) is a chronic form of leukocytoclastic vasculitis consisting of violaceous, red-brown, or yellowish papules, plaques, or nodules that favor the extensor surfaces.

EED may occur in association with infections, hematologic abnormalities, autoimmune diseases, or other conditions.

SYNONYM

EED

ICD-10CM CODE
L951 Erythema elevatum diutinum

EPIDEMIOLOGY & DEMOGRAPHICS

- EED is a rare disease.
- It most frequently affects young and middle-aged adults between the ages of 30 and 60 yr.
- There is no known sex or racial predilection.

ASSOCIATED FACTORS

- Infections: HIV infection, beta-hemolytic streptococcal infections, hepatitis, and tuberculosis.
- Hematologic disorders: Plasma cell dyscrasias (particularly IgA monoclonal gammopathies), myelodysplasia, myeloproliferative disorders, B-cell lymphoma, and hairy cell leukemia. EED may appear yrs after the diagnosis of the hematologic disease.
- Autoimmune disease: Inflammatory bowel disease, rheumatoid arthritis, celiac disease, relapsing polychondritis, lupus erythematosus, granulomatous polyangiitis, and dermatomyositis.
- Other sporadic reports of disease associations include breast carcinoma and dermatitis herpetiformis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- EED most commonly manifests as a bilateral eruption of violaceous, red-brown, or yellowish papules, plaques, or nodules.
- Early EED tends to be soft and erythematous.
- Older lesions are often more firm secondary to fibrosis.
- EED is most frequently found on acral skin and periarticular skin.
- The extensor surfaces of the elbows (Fig. E1), knees, ankles, hands, and fingers (Fig. E2) are commonly involved.
- Less frequently involved sites include the face, retroauricular area, trunk, axillae, buttocks, and genitalia.
- Nodular lesions progressing to bulky masses appear to be more common in patients with EED associated with human immunodeficiency virus (HIV) infection.
- Additional reported presentations of EED include annular plaques with raised borders, verrucous plaques on the soles, and vesicobullous presentations.
- The cutaneous manifestations of EED may be asymptomatic or associated with a burning or stinging sensation or pruritus (especially in early stages).
- Extracutaneous symptoms include arthralgia, fever, or other constitutional symptoms.
- Ocular abnormalities such as peripheral keratitis, nodular scleritis, panuveitis, and blindness also have been reported.

ETIOLOGY

- The pathogenesis of EED is not well understood.
- It appears to be a form of immune complex–mediated vasculitis.
- The cutaneous findings may result from the deposition of immune complexes in small blood vessels in the skin, leading to complement activation, neutrophilic infiltration, and the release of destructive enzymes.
- Direct immunofluorescence studies reveal perivascular deposition of complement, IgG, IgM, IgA, and fibrin in EED.
- In vitro studies suggest that activation of cytokines such as interleukin-8 contributes to selective recruitment of leukocytes to affected skin.
- Antineutrophil cytoplasmic antibodies (ANCA) may also be pathogenic in EED.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Granuloma faciale
- Sweet syndrome
- Rheumatoid neutrophilic dermatitis
- Palisaded neutrophilic and granulomatous dermatitis
- Rheumatoid nodules
- Multicentric reticulohistiocytosis
- Sarcoidosis
- Leprosy

FIG. E1 Erythema elevatum diutinum. Nodules typically form over the extensor surfaces of the knuckles and other joints. (Firestein GS et al: *Kelley's textbook of rheumatology,* Philadelphia, 2013, WB Saunders.)

WORKUP/LABORATORY TESTS/ IMAGING STUDIES

- Complete blood count, comprehensive metabolic panel
- Human immunodeficiency virus (HIV) test
- Immunofixation electrophoresis
- Streptozyme test
- Hepatitis B and C serology
- Antinuclear antibody (ANA)
- Antineutrophil cytoplasmic antibodies
- Anti-nDNA antibody, antiphospholipid antibodies
- Chest radiograph, urinalysis
- Specific testing for other infections or autoimmune diseases should be based upon the presence of suggestive signs, symptoms, or patient history

TREATMENT

NONPHARMACOLOGIC THERAPY

Local surgical excision can be beneficial for localized fibrotic nodules of EED.

ACUTE GENERAL Rx

Dapsone (with or without glucocorticoids) is the medical treatment of choice for EED.

CHRONIC Rx

Dapsone, colchicine, methotrexate, tetracycline

DISPOSITION

- EED usually has a prolonged course, characterized by fluctuating periods of exacerbation and stability.
- The disease may resolve spontaneously after 5 to 10 yr; however, persistence up to 40 yr has occurred.
- EED does not progress to systemic vasculitis.
- Recurrence is common after cessation of dapsone.

PEARLS & CONSIDERATIONS

- EED is a rare form of leukocytoclastic vasculitis consisting of violaceous, red-brown, or yellowish papules, plaques, or nodules that favor the extensor surfaces.
- It may occur in association with infections, hematologic disorders, or autoimmune diseases.
- The diagnosis of EED is made based upon correlation of the clinical and histologic findings.
- Treatments for EED have included local medications, systemic medications, and surgery.
- In addition, the associated underlying disease (when present) should be treated.
- Erythema elevatum diutinum exhibits a prolonged relapsing-remitting course.

REFERRAL

Ophthalmology, dermatology, rheumatology

AUTHOR: **Catherine E. Najem, MD**

FIG. E2 Erythema elevatum diutinum. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

Erythema Multiforme PTG

BASIC INFORMATION

DEFINITION

Erythema multiforme is an inflammatory disease characterized by eruption of annular, maculopapular lesions with dark raised, erythematous, or vesiculobullous center surrounded by a pale zone. It is believed to be caused by immune complex formation and subsequent deposition in the skin and mucous membranes. It is considered a hypersensitivity reaction to infection or drugs.

SYNONYM

EM

ICD-10CM CODES

L51.0 Nonbullous erythema multiforme
L51.8 Other erythema multiforme
L51.9 Erythema multiforme, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT AGE: 20 to 40 yr
RISK FACTORS: Often associated with herpes simplex and other infectious agents, drugs, or connective tissue diseases

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Prodromal symptoms are mild or absent. Itching or burning at the site of eruption may occur.
- Symmetric skin lesions (Fig. E1) with a classic "target" appearance (caused by the centrifugal spread of red maculopapules to circumference of 1 to 3 cm with a purpuric, cyanotic, or vesicular center) are present (Fig. E2). The papules may enlarge into plaques measuring a few centimeters in diameter with a dark or red central portion (Fig. E3). Target lesions may not be apparent for several days and generally heal in 1 to 2 wk without scarring.
- EM lesions are most common on the face, back of the hands and feet, and extensor aspect of the forearms and legs (EM minor). Trunk involvement can occur in severe cases (EM major).
- Urticarial papules, vesicles, and bullae may also be present and generally indicate EM major.
- EM major bullae and erosions may also be present in the oral cavity. The most common sites are the lips and buccal mucosa.

ETIOLOGY

- Immune complex formation and subsequent deposition in the cutaneous microvasculature may play a role in the pathogenesis of erythema multiforme.
- The majority of cases follow outbreaks of herpes simplex virus 1 and 2.
- *Mycoplasma pneumoniae,* fungal infections, medications (bupropion, sulfonamides, penicillins, nonsteroidal antiinflammatory drugs, barbiturates, phenothiazines, hydantoins).
- In >50% of patients no specific cause is identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Chronic urticaria
- Pityriasis rosea
- Contact dermatitis
- Pemphigus vulgaris
- Lichen planus
- Serum sickness
- Drug eruption
- Granuloma annulare
- Polymorphic light eruption
- Viral exanthema
- Stevens-Johnson syndrome (SJS)
- Toxic epidermal necrolysis (TEN)
- Bullous pemphigoid
- Viral exanthems
- Leukocytoclastic vasculitis
- Lupus erythematosus
- Secondary syphilis

WORKUP

- Medical history with emphasis on drug ingestion.
- Laboratory evaluation in patients with suspected collagen-vascular diseases.
- Skin biopsy when diagnosis is unclear.

LABORATORY TESTS

- Complete blood count with differential, elevated ESR
- Antinuclear antibody
- Serology for *Mycoplasma pneumoniae,* HSV-1, HSV-2
- Biopsy for atypical cases
- Direct immunofluorescence if suspecting bullous diseases

TREATMENT

NONPHARMACOLOGIC THERAPY

- Mild cases generally do not require treatment; lesions resolve spontaneously within 1 mo.
- Potential drug precipitants should be removed.

ACUTE GENERAL Rx

- Treatment of associated diseases (e.g., valacyclovir or famciclovir for herpes simplex, erythromycin for *Mycoplasma* infection).
- Dapsone, antimalarials, or azathioprine for severe or resistant cases.
- Prednisone 40 to 80 mg/day for 1 to 3 wk is effective for decreasing inflammation and pain and may be tried in patients with many target lesions; however, the role of systemic steroids remains controversial.
- Levamisole, an immunomodulator, may be effective in the treatment of patients with chronic or recurrent oral lesions (dose is 150 mg/day for 3 consecutive days used alone or in combination with prednisone).
- IV immunoglobulins in severe cases.
- Antimicrobial therapy is indicated if *M. pneumoniae* is the trigger of EM.

DISPOSITION

The rash generally evolves over a 2-wk period and resolves within 3 to 4 wk without scarring. A severe bullous form can occur (see entry for "Stevens-Johnson Syndrome").

REFERRAL

Hospital admission in patients with suspected Stevens-Johnson syndrome

PEARLS & CONSIDERATIONS

COMMENTS

The risk of recurrence of erythema multiforme exceeds 30%. Recurrence may be treated with valacyclovir 500 to 1000 mg/day, famciclovir 125 to 250 mg/day, or acyclovir 400 mg bid. Dapsone, antimalarials, azathioprine, or cyclosporine use is reserved for cases resistant to antivirals.

RELATED CONTENT

Erythema Multiforme (Patient Information)
Stevens-Johnson Syndrome (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

FIG. E1 Erythema multiforme (EM). Round erythematous swollen plaques and target lesions on the palms. This girl developed EM in association with her systemic lupus erythematosus. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E2 Erythema multiforme. Classic target lesions and marginated wheals with central vesicles are characteristic. (From Paller AS, Mancini, AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Erythema multiforme. Extensive target lesions on the thighs of a 12-yr-old girl. The recurrent reaction was suppressed by administration of oral acyclovir. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Erythema nodosum (EN) is an acute, tender, erythematous, nodular skin eruption resulting from inflammation of subcutaneous fat, often associated with bruising. It is the most common form of panniculitis.

SYNONYM

EN

ICD-10CM CODE
L52 Erythema nodosum

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: It is the most common form of panniculitis. Two to three cases/100,000 persons per yr.
PREDOMINANT SEX: Female:male ratio of 3 to 4:1
PREDOMINANT AGE: 25 to 40 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Prodromal symptoms of fatigue, malaise, upper respiratory infection symptoms may precede eruption by 1 to 2 wk.
- Acute onset of tender nodules typically located on the shins and occasionally seen on the thighs and forearms (Fig. E1).
- The nodules are usually 1/8 to 1 inch in diameter but can be as large as 4 inches; they begin as light red lesions, then become darker and often ecchymotic. The nodules heal within 8 wk without ulceration.
- Associated findings:
  1. Fever (60%)
  2. Lymphadenopathy (<50%)
  3. Arthralgia (64%)
  4. Signs of the underlying illness

ETIOLOGY

Cell-mediated hypersensitivity reaction is seen more frequently in persons with human leukocyte antigen (HLA) B8. The lesion results from an exaggerated interaction between an antigen and cell-mediated immune mechanisms leading to granuloma formation. Up to 55% of cases of EN are idiopathic.
Infections:
- Bacteria:
  1. Campylobacter
  2. Streptococcal pharyngitis (28% to 48%)
  3. *Salmonella* enteritis
  4. *Yersinia* enteritis
  5. Psittacosis
  6. *Chlamydia pneumoniae* infection
  7. *Mycoplasma* pneumonia
  8. Meningococcal infection
  9. Gonorrhea
  10. Syphilis
  11. Lymphogranuloma venereum
  12. Tularemia
  13. Cat-scratch disease
  14. Leprosy
  15. Tuberculosis
- Fungi:
  1. Histoplasmosis
  2. Coccidioidomycosis
  3. Blastomycosis
  4. *Trichophyton verrucosum*
- Viruses:
  1. Cytomegalovirus
  2. Hepatitis B
  3. Epstein-Barr virus
- Drugs (3% to 10%):
  1. Sulfonylureas
  2. Sulfonamides
  3. Penicillins
  4. Oral contraceptives
  5. Gold salts
  6. Prazosin
  7. Aspirin
  8. Bromides
- Sarcoidosis (11% to 25%)
- Inflammatory bowel disease
- Hodgkin disease, non-Hodgkin lymphoma
- Ankylosing spondylosis and reactive arthropathies (e.g., associated with inflammatory bowel disease)
- Behçet disease
- Löfgren syndrome
- Acute myelogenous leukemia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Insect bites
- Posttraumatic ecchymoses
- Vasculitis
- Weber-Christian disease
- Fat necrosis associated with pancreatitis
- Necrobiosis lipoidica
- Scleroderma
- Lupus panniculitis
- Subcutaneous granuloma

WORKUP

- Physical examination
- Diagnosis of underlying illness by history, physical examination, and laboratory tests as indicated

LABORATORY TESTS

- Erythrocyte sedimentation rate
- Throat culture and antistreptolysin O titer
- Purified protein derivative
- Others depending on index of suspicion (e.g., stool culture and evaluation for ova and parasites in patients with diarrhea and gastrointestinal symptoms)
- Skin biopsy in doubtful cases:
  1. Early lesion: Inflammation and hemorrhage in subcutaneous tissue
  2. Late lesion: Giant cells and granulomata

IMAGING STUDIES

Chest radiograph to rule out sarcoidosis and tuberculosis

TREATMENT

- The disease is self-limited and treatment is symptomatic. EN nodules develop in pretibial locations and resolve spontaneously over several weeks without scarring or ulceration.
- Treatment of underlying disorders.
- Avoidance of contact irritation of affected areas.
- Nonsteroidal antiinflammatory drugs for pain.
- Systemic steroids (prednisone 1 mg/kg of body weight/day, tapered over several days) may be useful in severe cases if underlying risk of sepsis and malignancy have been excluded.
- Potassium iodide given as tablet 300 mg tid or as a supersaturated solution (five drops three times/day in orange juice) has been reported as effective for symptom control.
- Intralesional corticosteroid injections for persistent lesions.

PROGNOSIS

Typical case:
- Pain for 2 wk
- Resolution within 8 wk

RELATED CONTENT

Erythema Nodosum (Patient Information)
Sarcoidosis (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

FIG. E1 Erythema nodosum. Tender, red, oval nodules on the extensor aspect of the legs. Note that several have darkened and resemble bruises. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

Esophageal Tumors ALG PTG

BASIC INFORMATION

DEFINITION

Esophageal tumors include benign and malignant neoplasms of the esophageal mucosa and wall. Carcinomas of the esophageal epithelium, both squamous cell carcinoma and adenocarcinoma (including adenoacanthoma, mucoepidermoid, and adenoid cystic), are the most common tumors of the esophagus. Rare esophageal tumors include both malignant (spindle cell, small cell, sarcoma, lymphoma, melanoma, and choriocarcinoma) and benign neoplasms (leiomyoma, papilloma, and fibrovascular polyps). One can also develop metastatic disease from a cancer that originated in another organ, but this is very rare. Breast cancer, lung cancer, and melanoma would be the most likely culprits. Approximately 15% of esophageal tumors arise in the proximal esophagus, 50% in the middle third of the esophagus, and 35% in the lower third. Tumors involving the esophageal-gastric junction are usually staged and treated as esophageal cancers if the tumor epicenter is no more than 2 cm into the proximal stomach. Tumors in the upper two thirds are usually squamous cell cancers, and tumors in the lower third are usually adenocarcinomas. The incidence of superficial esophageal cancers is increasing. These invade no deeper than the submucosa.

ICD-10CM CODES

C15.X	Malignant neoplasm of the esophagus (X defines location)
C15.3	Malignant neoplasm of upper third of esophagus
C15.4	Malignant neoplasm of middle third of esophagus
C15.5	Malignant neoplasm of lower third of esophagus
D00.2	Carcinoma of esophagus, in situ

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: It is the eighth most common cancer worldwide and the seventh leading cause of cancer deaths. Rates are increasing every decade and are highest in the Asian esophageal cancer belt, extending from the Caspian Sea to northern China, with certain high-incidence pockets in Finland, Ireland, southeast Africa, and northwest France. Incidence has increased six-fold since 1975. Foods including cured meats and spicy regional fare likely play a role in certain areas. Rates of squamous cell carcinoma are decreasing while those of adenocarcinomas are dramatically increasing. The causes of squamous cell carcinoma most commonly include tobacco and alcohol abuse. Epithelial dysplasia usually occurs, which progresses to carcinoma in situ. Adenocarcinomas are usually the result of GERD and obesity. The mucosa of the esophagus undergoes intestinal metaplasia. Genetic alterations occur, which perpetuate the cell changes during proliferation.

PREVALENCE: In the U.S., there was an estimated 16,000 new cases and 15,000 deaths are reported yearly, making it the seventh leading cause of death by cancer among men. The majority of cases are diagnosed at an advanced stage (unresectable or metastatic disease).

RACE, AGE, & SEX PREDOMINANCE: In the U.S., squamous cell esophageal cancer is more common among those of African descent than whites, whereas adenocarcinoma is more common in whites than in those of African descent. The overall male:female ratio is 3 to 4:1; the highest male/female ratio is in the Hispanic population. It usually develops in the fifth to seventh decades and is associated with lower socioeconomic status.

GENETICS: Increasing evidence shows that genetics may play a role by increasing susceptibility to esophageal cancer. One well-identified disease associated with esophageal cancer is tylosis (focal non-epidermolytic palmoplantar keratoderma), linked to loss of heterozygosity on chromosome 17q. Familiar clustering of Barrett esophagus and the recent identification of germline mutations in affected sibling pairs support a genetic link to esophageal adenocarcinoma. Also, up to 35% of esophageal adenocarcinomas can have overexpression of HER2, which can lead to the use of targeted therapy (trastuzumab) in the treatment plan.

CLINICAL PRESENTATION

Symptoms and signs:

- Dysphagia (74%): Initially with solid foods, gradually progresses to semisolids and liquids; the latter signs usually indicate incurable disease with tumor involving more than 60% of the esophageal circumference. It may be felt as chest pain
- Unintentional weight loss: Usually of short duration. Losing >10% of body mass predicts poor outcome
- Hoarseness: Suggests recurrent laryngeal nerve involvement
- Odynophagia and halitosis: Unusual symptoms
- Cervical adenopathy: Usually involving supraclavicular lymph nodes
- Dry cough: Suggests tracheal involvement
- Aspiration pneumonia: Caused by fistula between the esophagus and trachea
- Iron deficiency anemia: Related to chronic GI blood loss
- Massive hemoptysis or hematemesis from the invasion of vascular structures
- Advanced disease spreads to lymph nodes, liver, lungs, peritoneum, and pleura
- Hypercalcemia: Associated with squamous cell carcinoma from secretion of a parathyroid-like tumor peptide

Clinical findings:

- 50% to 60% of patients present with the inoperative stage of their disease (locally advanced, regional, or metastatic).

ETIOLOGY

The pathogenesis of esophageal cancers is attributable to chronic recurrent oxidative damage from any of the following etiologic agents, which cause inflammation, and esophagitis, increased cell turnover, and, ultimately, initiation of the carcinogenic process.

ETIOLOGIC AGENTS: Squamous cell carcinoma

- Excess alcohol consumption is strongly associated with squamous cell esophageal cancer in the United States; hard liquor is associated with a higher incidence than wine or beer.
- Tobacco and alcohol synergistically increase risk for squamous cell cancer
- Other ingested carcinogens:
  1. Nitrates (converted to nitrites): South Asia, China
  2. Smoked opiates: Northern Iran
  3. Fungal toxins in pickled vegetables
  4. Betel nut chewing
- Mucosal damage:
  1. Long-term exposure to extremely hot tea (>70 °C [158 °F])
  2. Lye ingestion
- Radiation-induced strictures
- Achalasia: Incidence of esophageal cancer is seven times greater in this population
- Host susceptibility as a result of precancerous lesions:
  1. Plummer-Vinson syndrome (Paterson-Kelly): Glossitis with iron deficiency
  2. Congenital hyperkeratosis and pitting of palms and soles (tylosis)
- Human papillomavirus infection (particularly types 16 and 18) has been variably detected in squamous cell carcinoma of the esophagus, sometimes associated with p53 tumor suppressor gene mutations
- Questionable relationship with prolonged bisphosphonate use (≥10 prescriptions, or use >3 yr)
- Possible association with celiac sprue or dietary deficiencies of molybdenum, selenium, zinc, vitamin A

ADENOCARCINOMA: The incidence of adenocarcinoma is continually rising, whereas that of squamous cell carcinoma is unchanged.

- Smoking increases the risk of developing adenocarcinoma, particularly in patients with Barrett.
- Obesity, hiatal hernia, and diets lacking in fresh fruit and vegetables and high in fat (particularly from red meat and processed foods).
- Chronic GERD leading to Barrett metaplasia and adenocarcinoma via immune cell infiltration and production of inflammatory mediators and reactive oxygen species. The annual rate of transformation from Barrett to adenocarcinoma is <0.5%.
- *H. pylori* infection may reduce the risk of adenocarcinoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Achalasia
- Scleroderma of the esophagus
- Diffuse esophageal spasm
- Esophageal rings and webs

LABORATORY TESTS

Complete blood cell count, blood chemistry, and liver enzymes should be obtained at diagnosis. No biomarkers are currently recommended to

diagnose, monitor, or predict outcomes. While both the CEA and CA-19-9 can be elevated in patients with esophageal cancer (up to 70%), the sensitivity is low (18 % to 35%) and there is no proven predictive value.

IMAGING STUDIES

Imaging studies are important not only for diagnosis but for accurate staging:

- Esophagogastroduodenoscopy (EGD) (Fig. E1) should be performed initially to visualize smaller tumors, which may be missed by esophagogram, and to allow histopathologic confirmation.
- Endoscopic inspection of the larynx, trachea, and bronchi may identify concomitant cancers of head, neck, and lung ("triple endoscopy").
- Endoscopic ultrasound (EUS) (Fig. E1) appears to be the most accurate method for locoregional staging: to determine the depth of tumor invasion and to assess for and possibly obtain fine needle aspiration biopsies of suspicious lymph nodes.
- PET CT has become the standard of care, along with EUS, for the most accurate staging. These modalities can determine tumor spread for preoperative staging. CT scans of the chest (Fig. E2) and abdomen are more useful for restaging patients after initial therapy.
- Staging laparoscopy may alter treatment plans in 20% to 30% of cases by more accurately staging regional lymph nodes and detecting occult peritoneal metastases.
- Double-contrast esophagogram effectively identifies large esophageal lesions.
  1. In contrast to benign esophageal leiomyomata, which cause narrowing with preservation of normal mucosal pattern, esophageal carcinomas cause ragged ulcerating mucosal changes in association with deeper infiltration.

STAGING

Table 1 describes the TNM staging system for cancer of the esophagus from the American Joint Committee on Cancer Criteria. Fig. 3 illustrates an algorithm for staging thoracic esophageal cancer.

TABLE 1 TNM Staging System for Cancer of the Esophagus (American Joint Committee on Cancer Criteria)

Primary Tumor (T)*	
T_X	Primary tumor cannot be assessed
T_0	No evidence of primary tumor
T_{is}	High-grade dysplasia†
T_1	Tumor invades lamina propria, muscularis mucosae, or submucosa
T_{1a}	Tumor invades lamina propria or muscularis mucosae
T_{1b}	Tumor invades submucosa
T_2	Tumor invades muscularis propria
T_3	Tumor invades adventitia
T_4	Tumor invades adjacent structures
T_{4a}	Resectable tumor invading pleura, pericardium, or diaphragm
T_{4b}	Unresectable tumor invading other adjacent structures, such as aorta, vertebral body, trachea, etc.
Lymph Node (N)‡	
N_X	Regional lymph nodes cannot be assessed
N_0	No regional lymph node metastasis
N_1	Metastasis in 1-2 regional lymph nodes
N_2	Metastasis in 3-6 regional lymph nodes
N_3	Metastasis in 7 or more regional lymph nodes
Distant Metastasis (M)	
M_X	Metastasis cannot be assessed
M_0	No distant metastasis
M_1	Distant metastasis

TNM, tumor, node, metastases.
*(1) At least maximal dimension of the tumor must be recorded and (2) multiple tumors require the T(m) suffix.
†High-grade dysplasia includes all noninvasive neoplastic epithelia that was formerly called carcinoma in situ.
‡Number must be recorded for total number of regional nodes sampled and total number of reported nodes with metastasis.
From Edge S et al (eds): *AJCC cancer staging manual,* ed 7, New York, 2010, Springer.

Rx TREATMENT

TREATMENT OF ALL STAGES OF ESOPHAGEAL CANCER:

Although the histology of esophageal cancer can differ, most studies have combined tissue types in exploring treatment options. The histology develops secondary to differing pathogenesis and causative agents with tumor biology likely playing a role through varying mutations. The likelihood of response and prognosis can differ as well. However, as there is a lack of data on how histology should dictate the treatment approach, we therefore generally attack this cancer in a uniform manner as most studies have suggested the optimum benefit be obtained through a neoadjuvant chemoradiation approach followed by surgery when applicable in up to stage III disease.

COMBINATION THERAPY: CHEMORADIOTHERAPY FOLLOWED BY SURGICAL RESECTION: Induction chemotherapy that occurs before chemoradiation for patients with locally advanced but still possibly resectable disease has been given with good results. However, no studies have shown this being superior to chemoradiation alone. It can, however, provide relief of dysphagia. Standard fractionation 3D-RT is used in chemoradiotherapy.

- Chemotherapy is most often given with concurrent radiotherapy. Chemotherapy acts as a radiosensitizer and makes tumor cells more vulnerable to the effects of ionizing radiation, thus improving tumoricidal effects on cancer. Neoadjuvant chemoradiotherapy followed by surgery is the most common approach for patients with resectable disease but is employed primarily for patients with stage IIA or higher disease. Five-yr survival is improved with neoadjuvant approach (39%) versus surgery alone (16%). Several trials have now shown that preoperative therapy improves survival among patients with potentially curable esophageal or esophagogastric junction cancer. Neoadjuvant chemotherapy alone is another option for locally advanced disease, but results are not as good as with neoadjuvant chemoradiotherapy.
- Chemoradiotherapy followed by surgery should be offered to late stage I ($T_{1b}N_0$ or higher), stage II, and stage III esophageal cancer patients as the current standard of care. In several studies, this approach significantly improved local control, reduced recurrence, and reduced mortality compared with surgery alone in patients with resectable esophageal cancer. Trimodality therapy is the preferred treatment for most esophageal cancers.
- Chemoradiotherapy alone may be offered as the definitive treatment for patients who are not surgical candidates, and some of these patients may be cured.
- Combination chemotherapy using a platinum doublet (platinum agent plus second agent) can achieve significant tumor reduction in 30% to 60% of patients. Cisplatin, oxaliplatin, or carboplatin is usually given with 5-FU (5-fluorouracil) or paclitaxel to obtain the desired tumoricidal effects. Other chemotherapeutic agents with activity in esophageal cancer include irinotecan, epirubicin, and docetaxel.
- Capecitabine in combination with either cisplatin or oxaliplatin is as effective as 5FU in the neoadjuvant or definitive treatment setting.
- Complications of chemoradiotherapy primarily include mucositis, nausea, vomiting, diarrhea, myelosuppression, nephrotoxicity, ototoxicity, neurotoxicity with peripheral neuropathy, esophageal stricture, esophageal rupture, trachea-esophageal fistula (6%), and radiation pneumonitis. These can occur to varying degrees and are certainly more significant in the elderly and those with significant comorbidities.
- Postoperative adjuvant chemoradiotherapy should be offered to node-positive patients who underwent initial surgery alone.

SURGICAL RESECTION:

- Surgical resection of squamous cell carcinoma and adenocarcinoma of the middle esophagus and lower third of the esophagus is an acceptable initial modality for local and resectable disease in the absence of widespread metastases detected by CT-PET and transesophageal ultrasound (T_1 and T_2 tumors). Gastric pull-through or colonic interposition typically is used to provide luminal continuity.
- Endoscopic mucosal resection may replace radical surgical resection in patients with dysplasia and some small early tumors with no lymph node involvement (T_{is} or T_{1a}), but a recent Cochrane review found no studies comparing endoscopic treatment vs. surgery. Endoscopic mucosal resection may be beneficial for patients who are poor surgical candidates. It may be performed in conjunction with ablative therapies, including radiofrequency ablation, thermal ablation techniques, laser ablation, argon plasma coagulation,

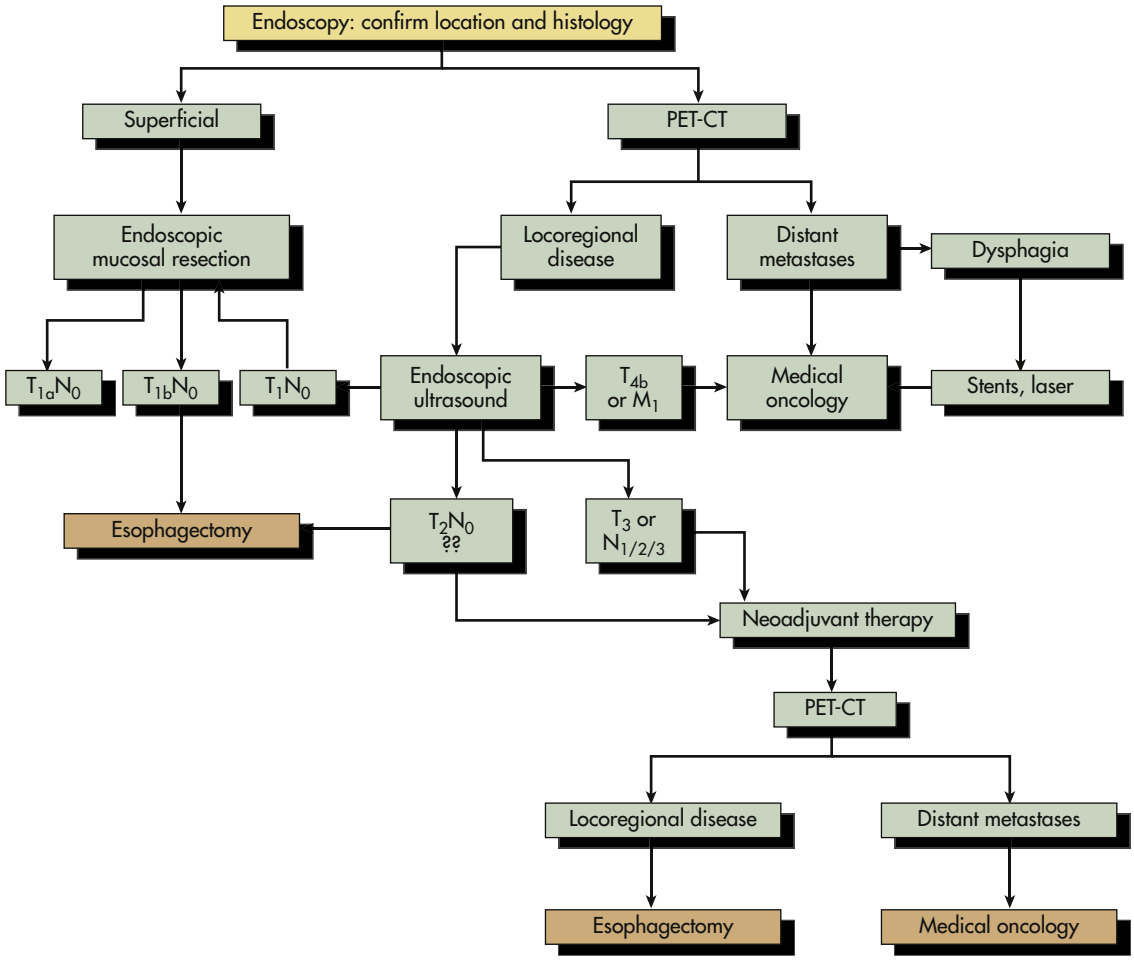

FIG. 3 An algorithm for staging a thoracic esophageal cancer patient. Metastatic disease must always be confirmed by pathologic evaluation of the tissue in question. *PET-CT,* Positron emission tomography–computed tomography. (From Sellke FW et al: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.)

or photodynamic therapy. Electrocoagulation (electrofulguration) is also being used and may aid in the relief of esophageal blockage.

- Complications of surgery:
  1. Anatomic fistula (usually with colon interposition, subphrenic abscesses).
  2. Respiratory complications.
  3. Cardiovascular complications are most common, including MI, CVA, and PE.
  4. Mortality is lower and clinical outcomes are better at high-volume hospitals and with minimally invasive surgery.
  5. Hybrid minimally invasive esophagectomy has been reported to have a lower incidence of intraoperative and postoperative major complications, specifically pulmonary complications, than open esophagectomy, without compromising overall and disease-free survival over a 3-yr period.[1]

Despite adequate preoperative staging, 25% of patients initially treated with surgical resection will have microscopically positive resection margins and are upstaged at the time of surgery. This has led to the majority of patients receiving neoadjuvant chemoradiotherapy as demonstrated in the CROSS Trial. The median disease-free survival for this group of patients was significantly prolonged as compared with the surgery-alone group. Death from recurrent cancer was decreased by 9% in the neoadjuvant group as well. The benefit of neoadjuvant therapy on survival was consistent regardless of histologic subtype.

PRE-TREATMENT PATIENT PREPARATION

The patient needs to stop smoking and drinking alcohol if at all possible. Before neoadjuvant or definitive chemoradiotherapy, the patient should have placement of an intravenous access device and a feeding tube (J-tube is preferable before surgical resection).

RADIATION THERAPY:

- Squamous cell carcinomas are more radiosensitive. Radiotherapy achieves good local control but is generally only used as monotherapy in a palliative mode for obstructive symptoms in patients with unresectable or advanced cancer or those with multiple comorbidities that limit treatment. It is best used for cervical esophageal tumors, but response rates are best when combined with chemotherapy.
- Radiotherapy in the preoperative/neoadjuvant setting is taken to a total dose of 40 to 50 Gy. For definitive therapy, the dose range is 50 to 55 Gy.
- Palliative radiotherapy for bone metastasis is also effective.
- Complications of radiotherapy: Can best be avoided by 3D conformal therapy.
  1. Esophageal stricture, fistula formation, radiation-induced pulmonary fibrosis, and transverse myelitis are the most common.
  2. Radiotherapy-induced cardiomyopathy and skin changes are rare.

IMRT can also be used for the treatment of esophageal cancers. It is associated with a more favorable toxicity profile. Very few studies have been completed to date using chemotherapy with IMRT and is therefore not considered a standard approach at this time for neoadjuvant therapy.

[1]Mariette C et al: Hybrid minimally invasive esophagectomy for esophageal cancer, *N Engl J Med* 380(2):152-162, 2019.

Brachytherapy: This is also an option for patients in a palliative mode. It provides high-dose radiation to a localized area and may prevent the need for a stent in patients with dysphagia. Its use is very limited in prior irradiated tissue for fear of fistula and perforation of the esophagus.

TREATMENT OF UNRESECTABLE, LOCALLY ADVANCED, OR METASTATIC DISEASE

- Combination chemotherapy regimens as a rule have a higher response rate than single-agent therapy. Response rates can be as high as 50% but that does not always translate into prolonged survival.
- Neoadjuvant chemotherapy regimens can also be utilized in locally advanced or metastatic settings. Cisplatin is probably the most active agent, and this combined with 5FU can yield response rates shown in several studies of 20% to 50%. If a taxane is added to this regimen in the metastatic setting, the triple drug regimen can lead to a prolongation in disease progression by about 2 mo, which may translate into prolonged survival. However, the patients have to be carefully chosen for this triple drug regimen because of increased toxicity. Other active double regimens can combine cisplatin with irinotecan, etoposide, or gemcitabine. Again, capecitabine can be substituted for 5FU in these regimens.

TARGETED MOLECULAR THERAPY

This is only applicable in adenocarcinoma of the esophagus that has overexpression of HER2. There is no apparent role for this treatment in squamous cell carcinoma.

- Ramucirumab is a recombinant monoclonal IgG1 antibody that is a vascular endothelial growth factor receptor 2 (VEGFR-2) antagonist. It inhibits ligand proliferation and migration of endothelial cells and ultimately inhibits angiogenesis. It is indicated for second-line therapy in conjunction with paclitaxel or as third line as monotherapy.
- Trastuzumab, in combination with cisplatin and 5FU, can be used as first-line therapy for metastatic esophageal cancer in patients with HER-2 overexpressing adenocarcinoma. Approximately 22% of adenocarcinomas will overexpress the type II epidermal growth factor receptor HER2. The overall response rate is 47%.

IMMUNOTHERAPY IN ESOPHAGEAL CANCER

- This involves an immune checkpoint inhibitor that targets PD-1.
- Studies have been done using nivolumab and pembrolizumab with varying response rates of 10% to 30% in patients who have progressive disease and failed traditional therapy with at least two previous chemotherapy regimens. Currently, only pembrolizumab is approved in the U.S. for treatment of esophageal cancer.

FOLLOW-UP CARE

The majority of recurrences develop within 12 months. Clinical monitoring, lab tests, imaging, and endoscopic evaluation where appropriate (particularly Barrett), are performed for postoperative surveillance, without clear benefit in earlier detection or decreased mortality. For patients who have undergone definitive therapy, it is recommended that endoscopic surveillance be performed every 3 mo for the first yr, and then annually. Palliative procedures such as repeated endoscopic dilation, endoscopic ablation, endoscopic mucosal resection, photodynamic therapy, brachytherapy, feeding tube insertion, or placement of expandable metal stents or polyvinyl prostheses to bypass tumors have been used for unresectable patients. The morbidity and mortality associated with resection in patients with advanced disease and/or for palliation argues against offering this modality to most of these patients.

SURVIVORSHIP

- Overall 5-yr survival for all stages at presentation is 15% (39% for localized disease, 21% for regional disease, and 4% for distant disease).
- Endoscopic therapy for highly selected stage 0 or stage I patients with disease limited to the submucosa may have 5-yr survival rates of 70% to 90%.
- Surgical resection without neoadjuvant treatment: 5-yr survival rate is 5% to 30%, with higher survival (up to 45% to 50%) in early-stage cancers.
- Radiation therapy without chemotherapy or surgery: 5-yr survival rate of 6% to 20%.
- Chemoradiotherapy without surgery: 5-yr survival up to 30%.
- Combined trimodality treatment: Up to 45% to 50% 5-yr survival rates (all stages of disease treated).
- Patients with metastatic disease have median survivals of less than 1 yr with palliative chemotherapy.

REFERRAL

- To gastroenterologist for endoscopy for patients with dysphagia, odynophagia, or unexplained weight loss, or for palliative care
- To medical oncologist for evaluation of preoperative chemotherapy and care of the metastatic patient
- To radiation oncologist for palliative therapy if tumor is actively bleeding, unresectable, or if obstruction is present
- To hospice if appropriate

PEARLS & CONSIDERATIONS

COMMENTS

More than 50% of patients with esophageal cancer are diagnosed when the disease is metastatic or unresectable.

PREVENTION

- A diet high in fruits, vegetables, and antioxidants may be associated with lower risk of esophageal cancer.
- Avoid tobacco and excessive alcohol use.
- Avoid ingested toxins known to cause esophageal cancers.
- Aspirin may have a chemopreventive role in Barrett but is only currently recommended for patients with other (e.g., cardiac) indications.
- There is no evidence that vitamins, Chinese herbal regimens, or green tea prevent esophageal cancer.
- Screening the general population is not recommended. If Barrett esophagus is detected, regularly scheduled surveillance endoscopies are necessary, with consideration for radiofrequency or other ablation therapy if dysplasia is detected.

PATIENT & FAMILY EDUCATION

Provide education and support about the likely prognosis because most esophageal cancers are diagnosed at an advanced stage.

Esophageal Varices ALG

BASIC INFORMATION

DEFINITION

Esophageal varices are dilated submucosal veins that occur in patients with underlying portal hypertension, function as a shunt between the portal venous and systemic venous circulation, and can result in severe upper GI hemorrhage.

ICD-10CM CODES

I85.00 Esophageal varices without bleeding
I85.01 Esophageal varices with bleeding

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Esophageal varices: 5% to 15% per yr in patients with cirrhosis
- Hemorrhage:
  1. One third of all patients with varices will develop hemorrhage.
  2. Variceal hemorrhage occurs in 25% to 40% of patients with cirrhosis.
  3. The risk of bleeding from varices is approximately 15% at 1 yr.
  4. Survivors of an episode of active bleeding have a 70% risk of recurrent hemorrhage within 1 yr.

PREVALENCE: Approximately 50% of patients with cirrhosis have varices at the time of diagnosis.

RISK FACTORS: Cirrhosis, low platelet count and advanced Child-Pugh class, hepatitis C with advanced fibrosis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Often asymptomatic until acute upper GI hemorrhage: Hematemesis, hypovolemia
- No physical findings specific for esophageal varices
- Stigmata of cirrhosis and portal hypertension may be evident: palmar erythema, telangiectasias, gynecomastia, testicular atrophy, jaundice, caput medusae, lower extremity edema, ascites, splenomegaly, hemorrhoids, asterixis

ETIOLOGY

- Portal hypertension results from obstruction to portal venous outflow, and varices subsequently develop in order to decompress the hypertensive portal vein and return blood to the systemic circulation.
- Varices may appear when portal vein pressures rise above 10 to 12 mm Hg.
- Cirrhosis is the most common cause of portal hypertension.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Budd-Chiari syndrome, cirrhosis, portal vein thrombosis, schistosomiasis, Wilson disease
- Other causes of upper GI bleeding: Duodenal or gastric ulcers, gastric cancer, Mallory-Weiss tear

WORKUP

Upper endoscopy, laboratory tests, and imaging

LABORATORY TESTS

- CBC:
  1. Anemia (blood loss, nutritional deficiencies, alcohol myelosuppression)
  2. Thrombocytopenia (hypersplenism, alcohol myelosuppression)
- Renal function panel:
  1. BUN: Often increased in setting of upper GI bleeding
  2. Creatinine: Often elevated by hypovolemia, monitor for hepatorenal syndrome
  3. Sodium: Dilutional hyponatremia
- Heme-positive stools
- Type and crossmatch: In preparation for blood transfusion
- INR/PT and PTT: Coagulation factors produced in liver and may be prolonged in liver disease or impairment
- Liver function tests: ALT/AST may be normal in cirrhotic patients due to longstanding fibrosis; elevated alkaline phosphatase and a direct hyperbilirubinemia may be present if cholestatic liver disease is present
- Serum albumin: Severe liver disease results in hypoalbuminemia

IMAGING STUDIES

Invasive:

- Esophagogastroduodenoscopy (EGD) (upper endoscopy):
  1. In all patients with cirrhosis, screen for the presence or absence of varices and determine subsequent risk for variceal hemorrhage.
  2. In patients with small varices (<5 mm) repeat EGD in 2 yr (unless decompensation occurs).
  3. In patients with compensated cirrhosis who do not have varices, screening is repeated every 2 to 3 yr.
  4. In patients with decompensated cirrhosis (ascites, hepatic encephalopathy, variceal hemorrhage, or jaundice), it is repeated every yr or at the time of first decompensation.
  5. Emergently performed if there is evidence of acute upper GI bleeding to diagnose and treat variceal hemorrhage.

Noninvasive:

- Esophagography with barium can diagnose esophageal varices (Fig. E1).
- Capsule endoscopy can also diagnose esophageal varices, although sensitivity is not yet established.
- CT scan (Fig. E2).

TREATMENT

NONPHARMACOLOGIC THERAPY

- Endoscopic variceal ligation (Fig. E3) is an alternative to nonselective beta-blockers for primary prophylaxis against variceal hemorrhage. It is also used in patients unable to tolerate beta-blockers.
  1. Typically for patients with medium or large varices at highest risk for hemorrhage (Child-Pugh B/C or red wale markings viewed on endoscopy)
  2. Usually two to four sessions
  3. May not be a permanent solution because varices can recur after initial eradication
  4. Associated with significant complications, including hemorrhage from banding-induced ulcerations
     a. Therefore should be performed by endoscopists with expertise in prophylactic banding
     b. First surveillance endoscopy 1 to 3 mo after obliteration, then every 6 to 12 mo indefinitely

ACUTE GENERAL Rx

- Variceal hemorrhage: Acute hemodynamic resuscitation with packed red blood cell transfusion, correct coagulopathy and thrombocytopenia, airway protection and intubation as necessary, antibiotics (ceftriaxone or norfloxacin) for SBP prophylaxis, octreotide maintained for 2 to 5 days in conjunction with endoscopic therapy. The use of balloon tamponade in the control of active variceal bleeding should be a last resort when other forms of therapy are not available or fail to achieve hemostasis. Balloon tamponade (Fig. E4) should be used only as a temporary means of stabilization and a bridge to a more definitive form of therapy.
- EGD to treat bleeding esophageal varices by esophageal band ligation or sclerotherapy (Fig. 5).

CHRONIC Rx

Primary prophylaxis (Fig. 6):

- Nonselective beta-blockers such as propranolol (20 mg twice daily), nadolol (40 mg once daily) or carvedilol (6.25 mg twice daily)
  1. Increase as tolerated for goal heart rate of approximately 55 beats/min
  2. Blocks the adrenergic dilatory tone in mesenteric arterioles, resulting in unopposed alpha-adrenergic mediated vasoconstriction and therefore a decrease in portal inflow

Secondary prophylaxis (Fig. E7):

- All patients with compensated cirrhosis who have bled from esophageal varices should receive esophageal band ligation and beta-blockers, unless beta-blockers are contraindicated.
  1. Transjugular intrahepatic portosystemic shunt or surgical shunt may be performed if bleeding from esophageal varices continues or recurs despite this dual therapy.
- For patients with decompensated cirrhosis there is evidence, although limited, against the use of prophylactic beta-blockers due to the risk for increased mortality.

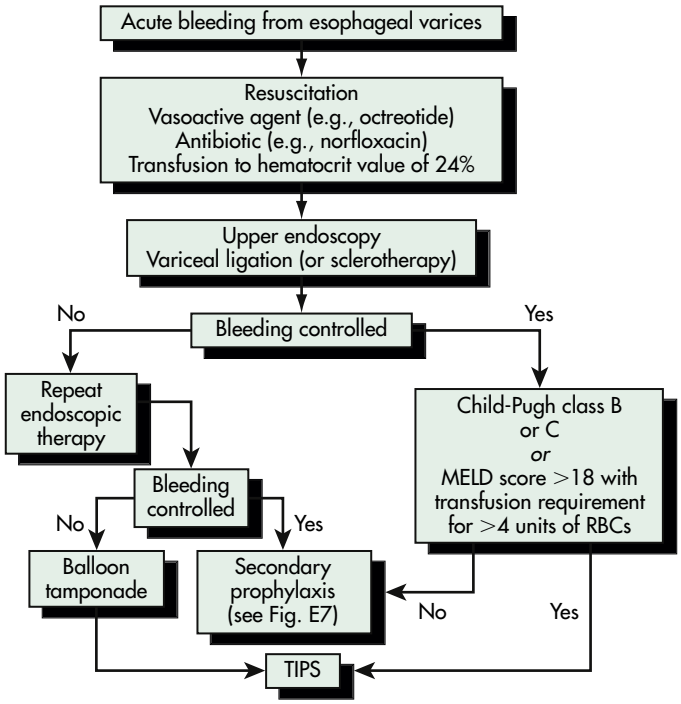

FIG. 5 Algorithm for the management of bleeding esophageal varices. *RBC,* Red blood cell; *MELD,* model end state liver disease; *TIPS,* transjugular intrahepatic portosystemic shunt. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

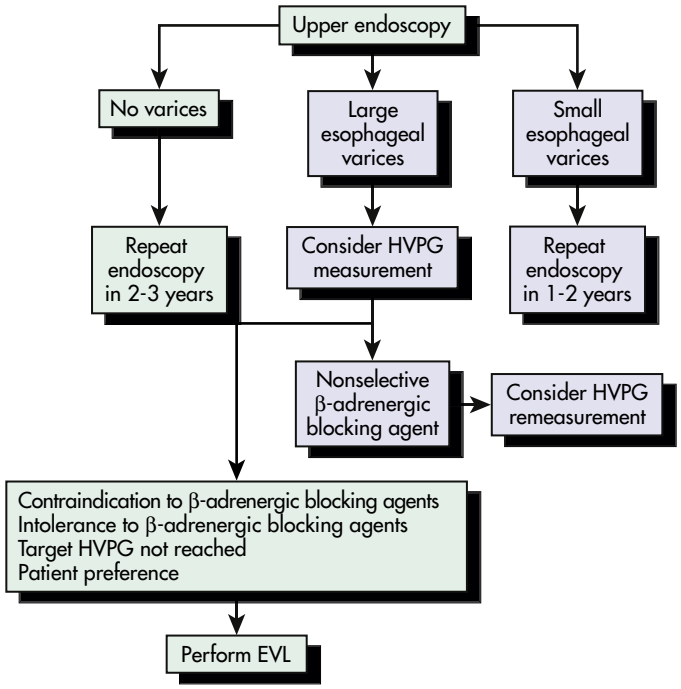

FIG. 6 Algorithm for the primary prophylaxis of esophageal variceal hemorrhage in patients with cirrhosis. The hepatic vein pressure gradient *(HVPG)* may be measured in patients with large varices before a nonselective β-adrenergic blocking agent is started and remeasured 1 mo after the maximum tolerated dose of the beta-blocker is reached. The goal of treatment is to reduce the HVPG to <12 mm Hg or by ≥20%. *EVL,* Endoscopic variceal ligation. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

REFERRAL

Consultation with a gastroenterologist is recommended in all patients with cirrhosis or portal hypertension in order to screen for esophageal varices.

PEARLS & CONSIDERATIONS

Besides variceal size, risk factors for variceal hemorrhage include Child-Pugh class B/C or variceal red wale markings on endoscopy.

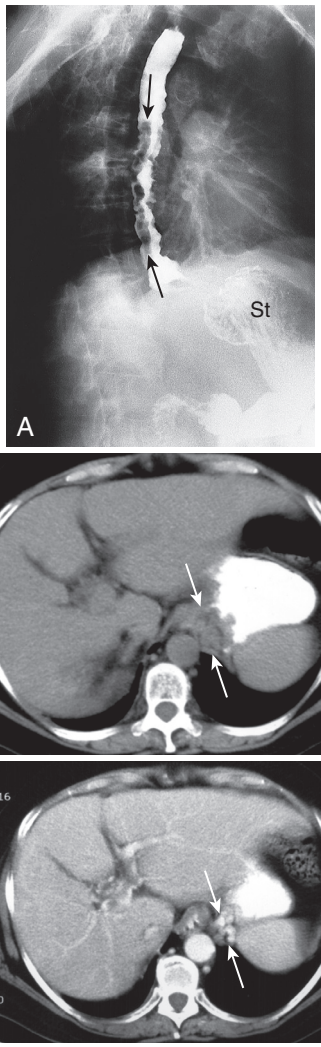

FIG. E1 Esophageal varices. In an oblique view from an upper gastrointestinal examination **(A)** performed on an alcoholic patient, a large, dark, wormlike filling density *(arrows)* is seen in the distal esophagus. It is caused by varices protruding into the lumen of the esophagus. The stomach *(St)* also is seen. Varices also can be seen on computed tomography (CT) scan. On a CT scan without intravenous contrast **(B),** they are seen as small, rounded structures *(arrows)*, and they may indent the fundus of the stomach. When intravenous contrast is given **(C),** they enhance and become whiter *(arrows)*. (From Mettler FA: *Essentials of radiology,* ed 3, Philadelphia, 2014, WB Saunders.)

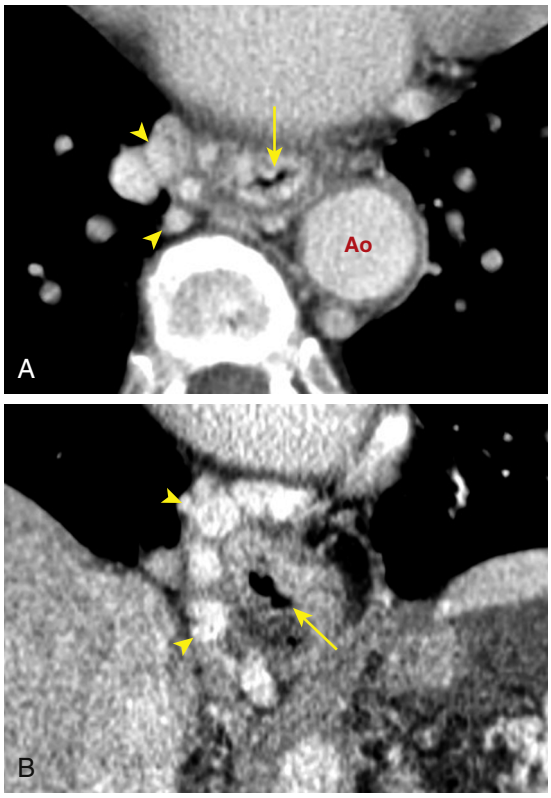

FIG. E2 Esophageal varices. Numerous large enhancing varices *(arrowheads)* resulting from cirrhosis and portal hypertension surround and indent the distal esophagus *(arrow).* **A,** Axial postcontrast computed tomography (CT). **B,** Coronal postcontrast CT in the same patient. *Ao,* Descending thoracic aorta. (From Webb WR et al: *Fundamentals of body CT,* ed 4, Philadelphia, 2015, WB Saunders.)

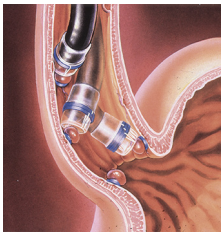

FIG. E3 Esophageal varices. Endoscopic band ligation performed with a multiple-band ligating device. The endoscopist makes circumferential contact between the end of the ligating device and the varix to be ligated. Endoscopic suction draws the varix into the device, after which the elastic band is ejected to ensnare the varix. The ligated tissue sloughs after 3 to 5 days, leaving a shallow ulceration that generally heals within 1 wk. (Courtesy Bard Endoscopic Technologies, Billerica, Mass.)

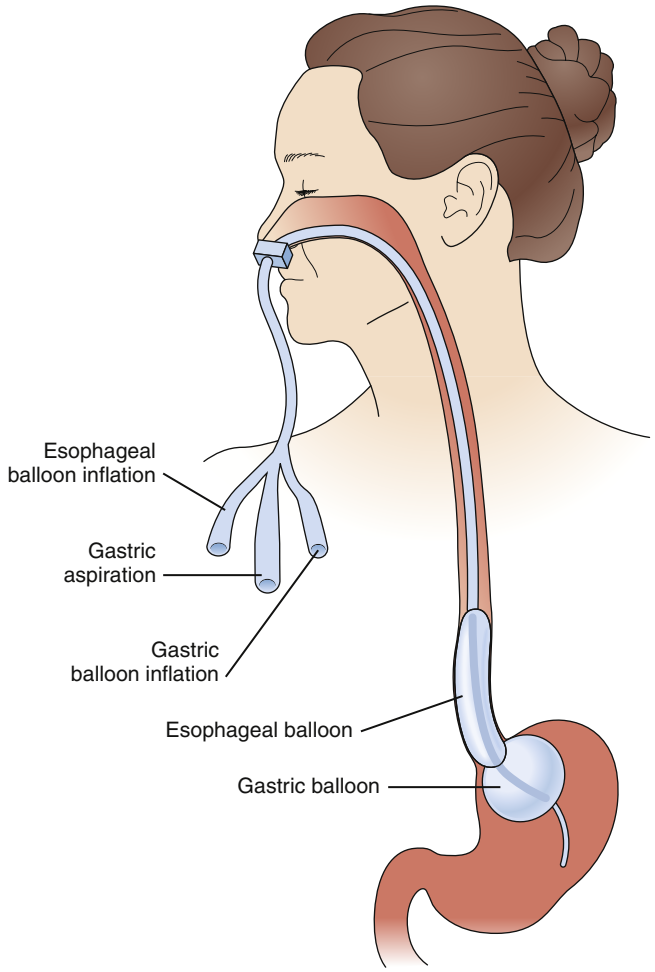

FIG. E4 Sengstaken-Blakemore tube. The tube is passed to at least the 50-cm mark. The gastric balloon is then inflated with the full recommended volume of air (usually 450 to 500 ml). A portable chest radiograph should be obtained to check for proper placement. The tube is pulled back gently until resistance is felt against the diaphragm. If bleeding persists from the aspiration port, the esophageal balloon is inflated to the lowest pressure needed to stop bleeding (usually 30 to 45 mm Hg). (From Parrillo JE, Dellinger RP: *Critical care medicine: principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.)

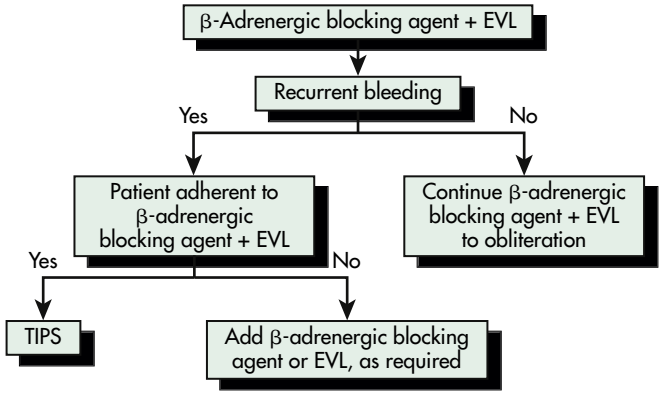

FIG. E7 Algorithm for the prevention of recurrent variceal bleeding (secondary prophylaxis). *EVL,* Endoscopic variceal ligation; *TIPS,* transjugular intrahepatic portosystemic shunt. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

Essential Tremor PTG

BASIC INFORMATION

DEFINITION

A tremor is an oscillatory movement of a body part. Essential tremor is a predominantly postural and action tremor that is bilateral and tends to progress slowly over the years in the absence of other neurologic abnormalities.

SYNONYMS

Benign essential tremor
Familial tremor

ICD-10CM CODE
G25.0 Essential tremor

EPIDEMIOLOGY & DEMOGRAPHICS

Essential tremor is one of the most prevalent neurologic diseases. It affects nearly 7 million persons in the U.S. It is the most common movement disorder.

PREDOMINANT AGE: Can begin at any age, but incidence increases after age 40 yr. Prevalence is 6% to 9% for those >60 yr of age.

GENETICS: Positive family history is found in 50% of patients. No gender or racial predominance.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Tremor (Fig. 1), 4 to 12 Hz, bilateral postural and action tremor of the upper extremities (90% to 95%), head (30%), legs (10% to 15%), and voice (20%). Typically, it is the same amplitude throughout the action, such as bringing a cup to the mouth.
- No other neurologic abnormalities on examination except difficulty with tandem gait.
- Symptoms worsen under emotional distress with fatigue or use of caffeine or other stimulants and improve with intake of small amounts of alcohol.

ETIOLOGY

Often an inherited disease in an autosomal dominant pattern. Sporadic cases without a family history can occur.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (SEE TABLE 1)

- Parkinson disease: The tremor is usually asymmetric, especially early on in the disease, and is predominantly a resting tremor. Patients with Parkinson disease will also have increased tone, decreased facial expression, slowness of movement, and shuffling gait.
- Cerebellar tremor: This is an intention tremor that increases at the end of a goal-directed movement (such as finger to nose testing). Other associated neurologic abnormalities include ataxia, dysarthria, and difficulty with tandem gait.
- Drug-induced: Many drugs enhance normal, physiologic tremor. These include caffeine, nicotine, lithium, levothyroxine, β-adrenergic bronchodilators, amiodarone, valproate, and SSRIs.
- Wilson disease: This is often characterized by a wing-beating tremor that is most pronounced with shoulders abducted, elbows flexed, and fingers pointing toward each other. Usually there are other neurologic abnormalities including dysarthria, dystonia, and Kayser-Fleischer rings on ophthalmologic examination.
- Physiologic tremor.

WORKUP

- Essential tremor is a clinical diagnosis. Review of medications is essential.
- All imaging studies (MRI, CT) are unnecessary unless other neurologic abnormalities are present.

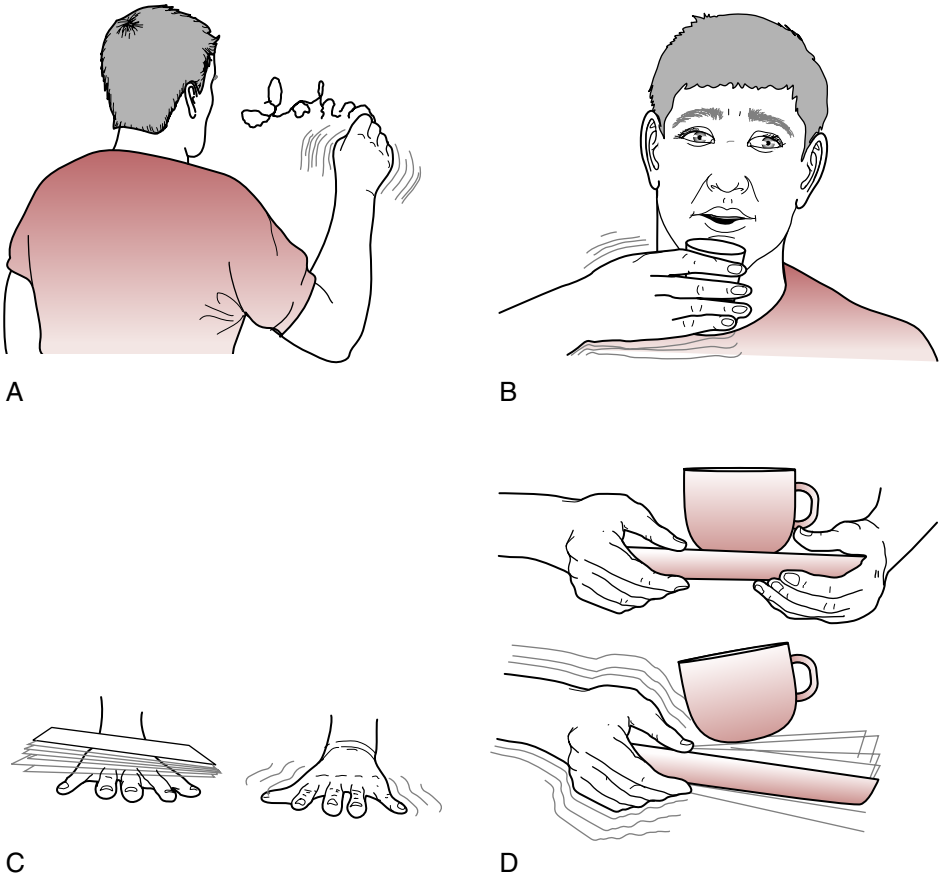

FIG. 1 Physicians elicit this 34-year-old gentleman's essential tremor by having him write his name **(A),** drink from a filled glass **(B),** support an envelope on his outstretched and pronated hand **(C),** or transfer a cup and saucer from one hand to the other **(D).** When his hands rest in his lap, the tremor completely subsides. Essential tremor is a prime example of an action tremor. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

TABLE 1 Overlapping Features of Various Types of Tremor

Feature	Parkinson Syndrome	Cerebellar Tremor	Essential Tremor
Present at rest	Yes	No	Yes
Increased tone	Yes	No	No
Decreased tone	No	Yes	No
Postural abnormality	Yes	Yes	No
Head involvement	Yes	Yes	Yes
Intentional component	No	Yes	Yes
Incoordination	No	Yes	No

From Remmel KS et al: *Handbook of symptom-oriented neurology,* ed 3, St Louis, 2002, Mosby.

- Obtain TSH to rule out hyperthyroidism.
- In patients younger than 40 yr old with other neurologic abnormalities, send ceruloplasmin, serum copper, and 24-hr urine copper to evaluate for Wilson disease.

Rx TREATMENT

Treat essential tremor when it is functionally impairing. Treatments are up to 75% effective.

NONPHARMACOLOGIC THERAPY

- Stress management
- Minimization of caffeine use if consumption is correlated with worsened symptoms
- Wrist weights and use of weighted utensils may be helpful in reducing tremor amplitude during feeding. Consumption of small quantities of alcohol at social functions, although relief may be short in duration and may be followed by tremor rebound
- A recent trial using MRI-guided focus ultrasound thalamotomy found it effective in reducing hand tremor in patients with essential tremor. Side effects included sensory and gait disturbances[1]

[1] Elias WJ et al: A randomized trial of focused ultrasound thalamotomy for essential tremor, *N Engl J Med* 375:730-739, 2016.

ACUTE GENERAL Rx

Propranolol (20 to 40 mg) may be used in preparation for specific event.

CHRONIC Rx

First-line agents:

- Propranolol/Inderal LA: Typical starting dose is 30 mg/day. The usual therapeutic dose is 160 mg/day. Although not contraindicated, this medication must be used with caution in those with asthma, depression, cardiac disease, and diabetes. Atenolol or sotalol are also effective.
- Primidone: Typical starting dose is 12.5 to 25 mg qhs. Usual therapeutic dose is between 62.5 and 750 mg daily (assuming side effects are tolerated). Sedation and nausea are common at treatment initiation.
- Topiramate: 25 mg qhs, may titrate up to about 400 mg.

Other (second-line) agents:

- Gabapentin: Typical starting dose is 300 mg tid. Usual therapeutic dose is 1200 to 3600 mg daily in divided doses.
- Pregabalin: Typical starting dose is 50 mg twice a day. Usual therapeutic dose is 150 to 600 mg per day in divided doses.
- Benzodiazepines (i.e., alprazolam): 0.125 to 3 mg daily in divided doses.
- Focal botulinum toxin injections.

SURGICAL Rx

Thalamic deep brain stimulation (or possibly thalamotomy) contralateral to side of tremor is reserved for resistant tremor or for patients who do not tolerate drug therapy. Surgical ablation of the neutral intermediate nucleus or the thalamus with use of magnetic resonance-guided focused ultrasound was recently FDA approved.

DISPOSITION

Patients should be reassured that the condition is not associated with other neurologic disabilities; however, it can become quite functionally disabling over time.

REFERRAL

This is a condition that usually can be treated by the primary care physician; however, if patient fails first-line therapies, the patient should be referred to a neurologist for other drug trials and discussion of possible surgical options.

PEARLS & CONSIDERATIONS

- Essential tremor is the most common of all movement disorders.
- In addition to motor dysfunction, essential tremor can cause significant psychological impact on patients in social situations.

Exocrine Pancreatic Insufficiency

BASIC INFORMATION

DEFINITION

Exocrine pancreatic insufficiency (EPI) is a serious condition characterized by a deficiency in pancreatic digestive enzymes resulting in inadequate digestion of fats, carbohydrates, and proteins. The most common cause of EPI is chronic pancreatitis (CP) in adults and cystic fibrosis (CF) in children. Clinically, EPI commonly results in fat malabsorption and is characterized by steatorrhea, weight loss, and maldigestion.

SYNONYMS

Pancreatic insufficiency
EPI
Fat malabsorption

ICD-10CM CODE
K86.81 Exocrine pancreatic insufficiency

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Approximately 40% in patients with CP and 90% in patients with CF
PREDOMINANT SEX & AGE: More common in males than females
RISK FACTORS:

- Excessive alcohol consumption, leading to recurrent pancreatitis and CP
- Smoking
- Bile ductal abnormalities
- Pancreatitis
- Genetic predisposition
- Intestinal surgery
- History of inflammatory bowel disease
- History of celiac disease

PHYSICAL FINDINGS & CLINICAL PRESENTATION

EPI manifests as a malabsorption syndrome. The clinical features may mimic and coexist with common gastrointestinal conditions (i.e., irritable bowel syndrome [IBS], small-intestinal bacterial overgrowth [SIBO], celiac disease), which may delay diagnosis. Patients often limit dietary fat intake to avoid or reduce steatorrhea. Severity depends on the degree of pancreatic loss and can be categorized into mild or moderate-to-severe disease as follows:

- *Mild disease*
  1. Asymptomatic
  2. Normal bowel movements
  3. Mild abdominal discomfort
  4. Bloating
- *Moderate-to-severe disease*
  1. Chronic diarrhea
  2. Excessive weight loss
  3. Excessive flatulence
  4. Abdominal pain/bloating
  5. Voluminous and foul-smelling stools
  6. Fatty food intolerance
  7. Failure to thrive in children
  8. Steatorrhea (stool fat >6 g/day) when >90% of pancreatic glandular function is loss
- Edema (as a result of protein malnutrition and hypoalbuminemia)
- Fat-soluble vitamins deficiencies (rare):
  1. Vitamin A (impaired night vision)
  2. Vitamin D (osteoporosis, metabolic bone disease, hyperparathyroidism, hypocalcemia)
  3. Vitamin E (neuropathy, anemia)
  4. Vitamin K (ecchymosis)

ETIOLOGY (TABLE 1)

EPI usually results from CP in adults or CF in children. Pancreatic exocrine insufficiency is also a common occurrence in patients recovering from severe acute pancreatitis, with the severity of symptoms correlating with the degree of pancreatic necrosis. Causative factors can generally be classified into pancreatic and extrapancreatic conditions.

DIAGNOSIS

The diagnosis of EPI is challenging because patients often present with nonspecific signs and symptoms, and reliable diagnostic tests are lacking.

DIFFERENTIAL DIAGNOSIS

With the exception of voluminous and foul-smelling stools, the following conditions may present in a manner similar to EPI:

- Celiac disease
- IBS
- Inflammatory bowel disease
- SIBO
- Short bowel syndrome

WORKUP

- A complete history, physical examination, and laboratory evaluation are essential to making the diagnosis and excluding other common causes of diarrhea and weight loss.
- Complete electrolyte panel to detect hypokalemia, hypocalcemia (in setting of vitamin D deficiency), hypomagnesemia, and metabolic acidosis from malabsorption and gastrointestinal losses.
- Complete blood count (CBC) may reveal anemia from iron, vitamin B_{12}, or folate deficiencies.
- Prolonged prothrombin times may be elevated because of vitamin K malabsorption.
- Alternative causes of maldigestion should be investigated, such as infection with *Giardia lamblia,* celiac serology, liver disease, and SIBO tests.

LABORATORY TESTS

Direct and indirect pancreatic function tests are available to diagnose EPI.

- **Indirect:** Measures the level of pancreatic enzymes or the consequences of exocrine insufficiency. Used to monitor the effectiveness of pancreatic enzyme replacement therapy (PERT).
  1. **Fecal fat quantification:** Considered the gold standard for evaluating fat digestion. However, it does not distinguish between maldigestion and malabsorption.
  2. **Fecal elastase-1 (FE-1):** The most sensitive and specific test of pancreatic function. This enzyme is minimally degraded during intestinal transit. The test measures enzymatic production of FE-1 and can be used to screen for moderate-to-severe EPI with high sensitivity. FE-1 levels >200 μg/g are normal, levels of 100 to 200 μg/g are considered mild, and levels <100 μg/g are severe for EPI. Liquid stool can lead to falsely low results because of dilution.
  3. **Fecal chymotrypsin:** Sensitive and specific test of pancreatic function. Variably degraded during transit in the intestinal lumen. Accurate levels require an interruption of PERT for several days.
  4. **Serum trypsinogen:** Reflects pancreatic acinar cell mass. Highly sensitive for severe EPI when levels <20 ng/ml. This test is not commonly employed in clinical practice.
  5. **^{13}C-Triglyceride breath test:** Monitors the digestion of isotope-labeled fat meal to reflect absorption and metabolization of product. It is used to measure the efficacy of PERT.
- **Direct:** Most sensitive and specific diagnostic tests for the diagnosis of EPI. Tests use hormonal secretagogues to stimulate the pancreas and then collect duodenal fluid to measure secretory content. Tests use CCK, secretin, and CCK-secretin.
  1. Endoscopic pancreatic function tests
  2. Secretin test

TABLE 1 Etiologiesof Exocrine Pancreatic Insufficiencies

Pancreatic	Extrapancreatic
Acute/chronic pancreatitis (alcohol abuse, trauma, hereditary, idiopathic)	Celiac disease
Pancreatic cancer	Inflammatory bowel disease
Pancreatic, ampullary, and duct obstruction	Autoimmune pancreatitis
Cystic fibrosis	Zollinger-Ellison syndrome
Diabetes mellitus type 1 or 2	Gastrointestinal surgeries (gastrectomy, gastric bypass, extensive small-bowel surgery)
Shwachman-Diamond syndrome (EPI with anemia, neutropenia, and bony abnormalities)	
Hemochromatosis	

IMAGING STUDIES

- Computed tomography (CT): First-line imaging study of choice. Permits visualization of calcifications, cysts, deformation/obstruction of bile ducts, pancreatic/peripancreatic tumors, fibrosis, and parenchyma loss.
- Magnetic resonance cholangiopancreatography: Provides 3D-imaging of the pancreaticbiliary ductal system.

Rx TREATMENT

The management of EPI includes dietary and lifestyle modifications, as well as PERT and vitamin supplementation, to relieve maldigestion-related symptoms and restore normal nutritional health. Underlying diseases leading to EPI should also be treated.

NONPHARMACOLOGIC THERAPY

Nutritional therapy aims to relieve maldigestion-related symptoms and ensure normal nutritional status. Patients should be encouraged to consume small and frequent meals. In addition, patients should abstain from consuming alcohol and smoking. Limiting dietary fat has not been shown to improve outcomes.

PHARMACOLOGIC THERAPY

Oral administration of pancreatic enzyme replacements (Table 2) is the method of choice for treatment of EPI. It is indicated for patients with weight loss, symptomatic steatorrhea, or steatorrhea of >15 g/day. The aim of PERT is to compensate for the deficiencies of normal pancreatic enzyme secretion and increase fat absorption. Doses are individually tailored but usually start at 25,000 to 40,000 IU of lipase in the form of enteric-coated mini-microspheres per main meal. Inadequate responses can be managed by either dose escalation or the addition of proton pump inhibitors or H_2 antagonists to prevent acid inactivation of lipase.

TABLE 2 Enzyme Products for the Treatment of Chronic Pancreatitis

Product	Formulation	Lipase Content per Pill or Capsule (USP units)
Creon	Enteric-coated capsule	3000; 6000; 12,000; 24,000; 36,000
Zenpep	Enteric-coated capsule	3000; 5000; 10,000; 15,000; 20,000; 25,000
Pancreaze	Enteric-coated capsule	4200; 10,500; 16,800; 21,000
Ultresa	Enteric-coated capsule	13,800; 20,700; 23,000
Pertzye	Enteric-coated with bicarbonate	8000; 16,000
Viokase	Non–enteric-coated tablet*	10,440; 20,880

The total dose of lipase per meal should be titrated based on response but usually requires at least 60,000 and usually 90,000 USP units (30,000 IU) of lipase per meal and half that amount with snacks. The dose should be split equally during the meal and immediately after the meal.

*Non–enteric-coated agents require cotreatment with an H_2 receptor antagonist or proton pump inhibitor to avoid denaturation of the enzymes by gastric acid.

USP, United States Pharmacopeia.

From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

DISPOSITION

- Consider further evaluation in patients with persistent weight loss and steatorrhea.

REFERRAL

- Consultation with a gastroenterologist can help expedite diagnosis and rule out alternate diagnoses.
- Referral to a nutritionist can aid the patient with malnutrition and alleviate symptoms.

PEARLS & CONSIDERATIONS

- The pancreas has an important role in the digestion of all nutrients, but fats in particular.
- EPI is a condition related to decreased pancreatic enzyme release resulting from loss of pancreatic parenchyma, inadequate pancreatic stimulation, pancreatic duct obstruction, or pancreatic enzyme inactivation.
- Common symptoms of EPI include weight loss, steatorrhea, and abdominal bloating.
- Timely diagnosis is crucial because delay may impair the child's growth, lead to adverse outcomes of malnutrition, and increase morbidity and mortality.
- Individualized dietary advice together with the appropriate PERT are the cornerstones of EPI therapy.

Factitious Disorder (Including Munchausen Syndrome)

BASIC INFORMATION

DEFINITION

Factitious disorder, according to the DSM-5, occurs when an individual feigns physical or psychological signs or symptoms or induces injury or disease with identified deception. Individuals present to others as ill, impaired, or injured and create signs or symptoms by lying, simulating (e.g., putting drops of blood into a urine sample), or actually creating disease (e.g., injecting bacteria or taking medications). The primary aim is to achieve the patient role, and the behavior persists even in the absence of apparent external rewards such as monetary gain or obtaining narcotics. While the behavior itself is engaged in consciously, the underlying motivation is unconscious. More is known about factitious physical disorder.

The individual may seek examination and treatment including invasive diagnostic testing or surgery. The term *Munchausen syndrome* is reserved for the most severe variant of factitious physical disorder and is characterized by exaggerated lying (pseudologia fantastica), sociopathy, geographic wandering (peregrinating) from hospital to hospital, and seeking the role of a patient.

SYNONYMS

Munchausen syndrome (severe form of factitious disorder)
Munchausen by proxy (factitious disorder created in another person, usually a child)
Hospital addiction syndrome
Surreptitious illness

ICD-10CM CODE
F68.10 Intentional production or feigning of symptoms or disabilities, either physical or psychological (factitious disorder)
DSM-5 CODE
300.19 Factitious disorder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Unknown
PREVALENCE (IN U.S.): Likely underdiagnosed because of the role of deception, but estimates range between 0.5% and 2%
PREDOMINANT SEX: Variable. With psychological subtype M > F; with predominant physical symptoms F > M by a ratio of 3:1. Munchausen syndrome M > F, and Munchausen by proxy mostly younger females
PREDOMINANT AGE: 30 to 40 yr of age
PEAK INCIDENCE: Approximately 30 to 40 yrs of age
GENETICS: No genetic predisposition known

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patient is inconsistent or intentionally misleading and resistant to allowing providers to obtain outside records.
- Clinical picture is atypical for the natural history of disease (e.g., an infection that does not respond to multiple courses of appropriate antibiotics).
- Tests, consultations, and medical and surgical treatments done to no avail and often contradicting history provided by the patient.
- Presentation may be acute and dramatic and in excess of what might be expected.
- The patient may predict deterioration or report exacerbation just before scheduled discharge.
- Opposition to psychiatric consultation.

ETIOLOGY

- A history of significant childhood illness; traumatic experiences such as having witnessed violence and physical, emotional, or sexual abuse can predispose.
- Personality disorders and psychodynamic factors often play a significant role in the development and maintenance of this disorder.

DIAGNOSIS

This is a diagnosis of exclusion. It requires demonstrating that the individual is taking surreptitious actions to misinterpret, simulate, or cause signs or symptoms of illness or injury in the absence of any obvious external reward. Early diagnosis is helpful to prevent extensive and unnecessary testing, which can cause iatrogenic injury.

There may be direct observation of fabrication, the presence of signs or symptoms that contradict laboratory testing, nonphysiologic response to treatment, physical evidence of fabrication (e.g., syringes at the bedside), recurrent patterns of illness exacerbation, or failure to follow the expected natural history of disease. Box E1 describes clues that increase the likelihood of subtle forms of factitious disease.

DIFFERENTIAL DIAGNOSIS

- Primary medical condition
- Somatic symptoms disorder: Not intentionally produced
- Conversion disorder
- Conditions in which self-injurious behavior is common such as borderline personality disorder. The goal is self-injury and not to attain the sick role
- Malingering: Clear secondary gain with conscious motivation (e.g., financial gain or avoidance of unwanted duties)

WORKUP

- Dictated by the presenting complaints. A reasonable index of suspicion when presentation is not consistent with known pathology.
- Methods that have been used to bolster or confirm a suspicion of self-induced or factitious disease are summarized in Box E2.

LABORATORY TESTS

- Laboratory testing often reveals inconsistencies.
- Laboratory abnormalities may reflect the underlying factitious behavior (e.g., hypokalemia in an individual surreptitiously taking furosemide or a clean urine sample obtained by straight catheterization in someone complaining of hematuria).

TREATMENT

NONPHARMACOLOGIC THERAPY

Two approaches may be considered:

- Nonpunitive constructive confrontation by the primary physician and a psychiatrist in collaboration. A supportive stance should be maintained and an offer for ongoing support and follow-up made. Box E3 summarizes consensus opinions on the treatment of factitious disease.
- Avoid overt confrontation with patient but provide him or her with a face-saving way to recover. For example, a therapeutic double bind would involve saying, "There are two possibilities here: one is that you have a medical problem that should respond to the next intervention we do, or two, you have a factitious disorder. The outcome will give us the answer." Features of supportive confrontation are described in Box E4.
- Munchausen syndrome is the most severe variant and may be virtually impossible to treat except to avoid further invasive and iatrogenic intervention.

BOX E1 Clues That Increase the Likelihood of Subtle Forms of Factitious Disease

Predominantly women
Previous experience in the medical field, which provides an unusual grasp of terminology and access to medical supplies
Multiple surgeries, multiple procedures
Inexplicable laboratory test results
Inconsistency and implausibility of certain aspects of the history
Visits to three or more medical centers previously for the same symptoms, or to a nationally known referral center such as the Mayo Clinic or Cleveland Clinic, despite residing far away
History of substance abuse or prior psychiatric disorder
Vagueness in regard to details of past history and/or reluctance to allow release of previous medical records

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

BOX E2 Methods That Have Been Used to Bolster or Confirm a Suspicion of Self-Induced or Factitious Disease

Review old medical records and discuss case with previous doctors and family members if appropriate. Identify discrepancies and inconsistencies, and estimate influence of gain derived from the sick role. Inquire about psychosomatic illness, previous psychiatric treatment, suicide attempts, stress in the patient's life, childhood abuse, marital/sexual problems, eating disorders, and so on. A forensic consultant with access to multiple records can be uniquely helpful in identifying conflicting stories.
Review previous biopsy slides, looking for foreign body material in wounds, melanosis coli, and other clues, as appropriate for the patient's symptoms.
Obtain a psychiatric evaluation to help determine whether the patient has a personality disorder or psychiatric disease, absence of which would argue against factitious disease. Psychiatrists should not attempt initially to discover the underlying unconscious motivation that may have impelled the patient to assume the sick role.
If symptoms and signs may be explained by surreptitious ingestion of medications and poisons, obtain appropriate medication and toxicology screens. Consider obtaining a urine test for diuretics even in the absence of renal or electrolyte disorders. Evaluate results of such screens in light of the sensitivity and specificity of the tests employed.
Test biological fluids collected under direct observation and compare results with fluids collected privately by the patient. For example, compare fecal material obtained at "unprepped" sigmoidoscopy with fecal material submitted by the patient.
Have nursing staff observe the patient to detect tampering behavior.
Search the patient's personal belongings.
Conduct covert videotape surveillance, especially in suspected Munchausen syndrome by proxy.

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

BOX E3 Consensus Opinions on the Treatment of Factitious Disease

Achievement of insight should not be the principal early goal of treatment, because it can weaken the patient's defenses.
One person should have primary responsibility for patient management.
There should be a comprehensive psychiatric evaluation of the patient, including assessment for suicide risk.
All members of a multidisciplinary team should be aware of the psychiatric assessment and treatment plan.
The treatment plan should be individualized.
Comorbid illness should be treated appropriately.
If confrontational techniques are used, they should be nonpunitive and supportive.

From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

BOX E4 Features of Supportive Confrontation

Tell the patient what you suspect without outright accusation.
Support the diagnosis of factitious disease with facts.
Provide empathetic and face-saving comments.*
Avoid probing to uncover the patient's underlying feelings and motivations.†
Assure the patient that the physician will not release the diagnosis to others without the patient's permission unless required to do so by law.‡
Ensure that the staff demonstrates continued acceptance of the patient.
Encourage psychiatric help, but do not force the issue.

*"Maybe you didn't know what you were taking—this medication could cause you to be sick"; "Maybe you took it in your sleep"; "What you did was a cry for help, and we understand"; "We realize you must be in great distress"; "We want to continue to take care of you."
†This is done to minimize disruption of essential emotional defenses.
‡Later it may be decided to break this promise in patients with potentially fatal factitious disease, such as patients who are creating sepsis by injecting contaminated material into their bodies. This promise should only be broken after consultation and consensus opinion has been obtained by an ethics committee, legal personnel, and others, as described in the text.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

ACUTE GENERAL Rx

- Treatment of comorbid psychiatric disorders may be helpful with medications and/or psychotherapy, which may ameliorate the factitious behavior.
- Multidisciplinary staff meetings can be useful to ventilate feelings and develop cohesive treatment plans.

CHRONIC Rx

- Attempt to engage the patient in some form of psychotherapy or at least a harm-reduction strategy.
- Establishment of a central reporting register has been proposed to aid development of evidence-based guidelines.

DISPOSITION

- After being confronted with their behavior, patients may cease factitious behavior, but they may also seek other physicians or hospitals, as in the Munchausen variant.
- Some patients may enter psychotherapy, particularly when they have been given a face-saving approach with avoidance of a humiliating confrontation.

REFERRAL

Always obtain psychiatric referral. Risk management attorneys and hospital ethicists may contribute to challenging decision making in these patients.

PEARLS & CONSIDERATIONS

- Think of factitious disorders whenever there is an unexplained medical course that continues to repeat itself despite appropriate treatment.
- Patients may have a history of working in the health care field.
- Gratuitous, self-aggrandizing deception may be noted.

BASIC INFORMATION

DEFINITION

Failure to thrive (FTT) describes a delay in growth and development among children. FTT is a cluster of symptoms rather than a specific disease.

CLINICALLY

The term (FTT) is often used for infants and children with weight below the 5th percentile for sex and corrected age.

SYNONYMS

Pediatric undernutrition
Faltering growth
Weight faltering
Growth failure
FTT

ICD-10CM CODE
R62.51 Failure to thrive (child)

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: FTT is a common problem, though its incidence in the community is unclear. A total of 1% to 5% of inpatient pediatric admissions are for evaluation of FTT.
PREDOMINANT SEX AND AGE: FTT most commonly occurs among children ages 6 to 12 mo, with 80% presenting before 18 mo of age. Most FTT patients present before 3 yr of age. Males and females are equally affected.
RISK FACTORS: Poverty is the single greatest risk factor. Nonmedical: Poverty, food insecurity, social isolation, neglect, and physical or emotional abuse. Medical: Intrauterine growth restriction (IUGR), prematurity, medical conditions leading to inadequate food intake, food malabsorption, or increased metabolic demand.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Children have blunted growth in height, weight, head circumference, or any combination of these. Children may have pallid, dry, or cracked skin, sparse hair growth, poorly developed musculature, lack of subcutaneous fat, swollen abdomen, or evidence of vitamin deficiencies.

ETIOLOGY

FTT is the result of inadequate nutrition, which may be due to a wide range of medical or psychosocial causes. FTT can be thought of as stemming from inadequate nutritional intake, malabsorption of nutrients, or increased caloric expenditure, though the actual cause is commonly multifactorial.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inadequate nutritional intake: Food insecurity, poor parent knowledge of child's needs, formula dilution, excessive juice, breastfeeding difficulties, neglect, behavioral feeding problem, oromotor dysfunction, developmental delay, emesis, gastroesophageal reflux, volvulus, increased intracranial pressure, genetic disease (trisomy 13, 18, 21), and psychiatric conditions
- Malabsorption: Cystic fibrosis, celiac disease, eosinophilic esophagitis, food protein insensitivity or intolerance, and inflammatory bowel disease
- Increased metabolic demand: Insulin resistance, congenital infection, other infection, genetic syndrome, hyperthyroidism, chronic disease, and malignancy

WORKUP

- Evaluation should include the child's eating habits, caloric intake, parent-child interactions, psychosocial history, past medical history, medications, family history to include parent stature and weight, review of systems, and physical exam. Fig. E1 illustrates an algorithm for management of a child with FTT.
- Height, weight, and weight-to-length measurements are most sensitive, whereas head circumference and body mass index (BMI) may be useful. Common FTT criteria for children younger than 2 yr are below, but clinical judgment should be used because normal causes and biologic variants may exist.
  1. Length, weight, or BMI below the 3rd or 5th percentile on more than one consecutive visit
  2. Weight that drops below two major percentile lines
  3. Weight less than 80% of the ideal weight for age
  4. Weight-to-length below the 5th percentile or weight-for-length less than 70% to 79% of the median
  5. Weight velocity below the 3rd or 5th percentile
  6. Weight less than 70% of the 50th percentile; may require hospitalization
- Obtain caliper measurements of skinfold thickness and midarm muscle circumference.
- Observation of a meal being taken to assess potential feeding difficulties.
- A 3-day food diary is helpful, as well as consultation by a nutritionist, to calculate the child's intake of energy, protein, vitamins, and minerals.
- Assess stool frequency, consistency, quantity, as well as fat, blood, or mucus content.
- Routine hospitalization for FTT evaluation is not recommended. Rarely, hospitalization for observed feedings and further workup is warranted.

LABORATORY TESTS

- Laboratory tests should be based on medical history and physical exam findings and should consider the risk for refeeding syndrome and other medical complications.
- Consider CBC with red blood cell indices, complete chemistry panel including phosphorus, thyroid function, urinalysis, HIV

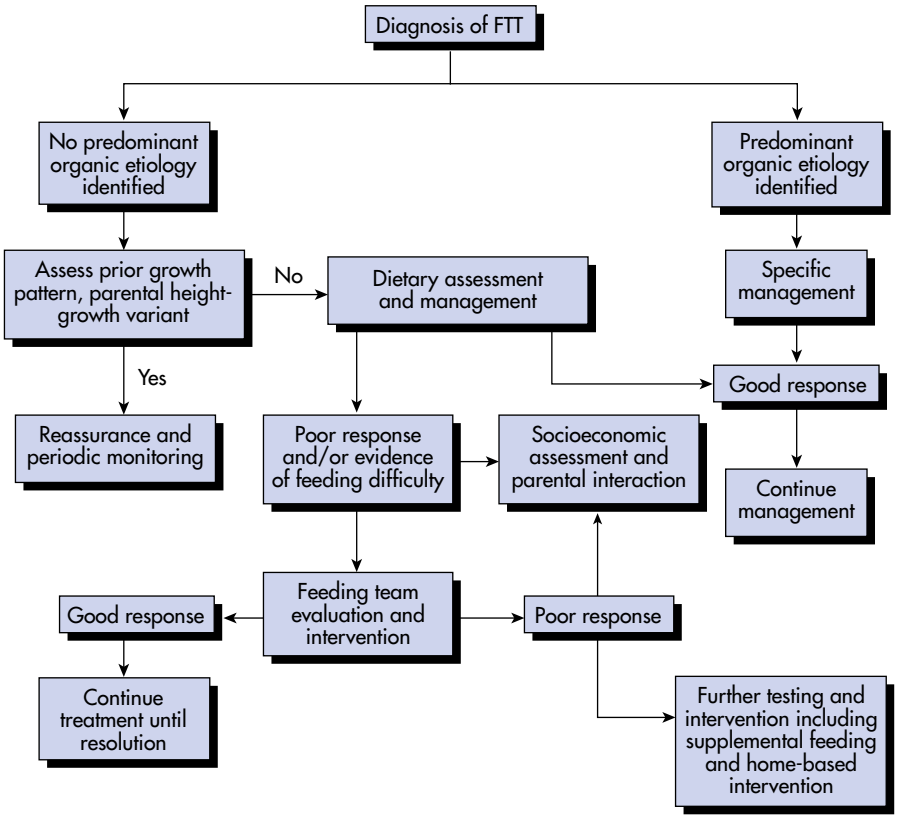

FIG. E1 Algorithm for management of a child with failure to thrive *(FTT).* (Shashidhar H, Tolia V: Failure to thrive. In Wyllie R, Hyams JS [eds], *Pediatric gastrointestinal and liver disease,* ed 4, Philadelphia, 2011, Elsevier, pp 136-145.e3.)

testing, C-reactive protein or erythrocyte sedimentation rate, celiac screening, stool examination for fats or reducing substances, or sweat chloride testing. If clinically indicated, growth hormone level and genetic sequencing can be checked.

IMAGING STUDIES

Imaging tests are not routinely performed but may be warranted depending on underlying medical cause.

Rx TREATMENT

Identification and management of underlying causes should be implemented. In cases in which there is no underlying medical condition, providing nutrition repletion will, by definition, correct FTT. A multidisciplinary team (including, but not limited to, social workers, occupational/speech therapists, nutritionists/dietitians, nurses, advanced practice nurses, and pediatricians) should be used.

NONPHARMACOLOGIC THERAPY

- Add calorie-dense foods or increase the number of feedings.
- Enteral feeding, percutaneous endoscopic gastrostomy (PEG), and nasogastric feeding tubes can be used to accelerate weight gain, and results should be seen within 2 to 7 days. Caloric intake should be titrated up to goal over 5 to 7 days. Caloric goals by age group: 0 to 6 mo: 108 kcal/kg/day, 6 to 12 mo: 98 kcal/kg/day, and 1 to 3 yr: 102 kcal/kg/day.
- Swift restoration of nutrition can lead to life-threatening refeeding syndrome, where shifts in electrolyte balance (low phosphate, magnesium, potassium), fluid balance (edema), hypoglycemia, gastroparesis or ileus, impaired heart function or arrhythmia, and sudden death can occur. Calories must therefore be titrated slowly to goal with close monitoring.
- Treat underlying medical conditions, including mental health disorders.
- Assist with family psychosocial stressors.
- Follow up closely, including home nursing visits.
- In cases where economic, psychosocial, or parental issues are suspected and the child's growth is not maintained, state and federal legislation regarding reporting to child protection services must be followed.

ACUTE GENERAL Rx

Multivitamins including iron and zinc

CHRONIC Rx

Nutrient repletion with the goal of accelerated growth should be continued for 4 to 9 months

DISPOSITION

Children with FTT commonly remain small in height and weight. Studies consistently find that children with FTT are more prone to long-term cognitive, learning, and behavioral abnormalities.

REFERRAL

- Indicated based on the cause of FTT
- Hospitalization should be considered in cases of FTT in which a child is less than 70% of predicted weight for length, where outpatient management has failed, when a suspicion of abuse or neglect exists, where signs of traumatic injury are present, where serious impairment of the child's caregiver is evident, or for close observation and treatment for refeeding syndrome.

PEARLS & CONSIDERATIONS

COMMENTS

- FTT is a common childhood symptom encountered in the outpatient and inpatient pediatric populations, is caused by undernutrition, and is associated with inadequate nutritional intake, malabsorption, or increased metabolic demand.
- A thorough multidisciplinary approach to assessment, diagnosis, and management should be used to manage nutrient status and any underlying cause(s).
- Child height/length, weight, and weight-for-length measurements with comparison to standard growth curves are useful in the identification of potential cases of FTT.
- FTT treatment should include restoration of nutrition along with treatment of the underlying cause(s), including psychosocial factors.
- Although FTT can usually be managed effectively in the outpatient setting, specific indications for inpatient treatment should be considered.

PREVENTION

Nutritional counseling and anticipatory guidance should be provided at each well-child visit. Growth parameters should be measured during serial clinical assessments and compared with growth standards. Enlist dietitians and visiting nurses to provide support to families with children at high risk of FTT.

BASIC INFORMATION

DEFINITION

A "primary" fallopian tube tumor is defined as a tumor that is restricted to or mainly affects the fallopian tube.

SYNONYMS

Fallopian tube cancers, serous tubal intraepithelial carcinomas

ICD-10CM CODES

C57.00	Malignant neoplasm of unspecified fallopian tube
C57.01	Malignant neoplasm of right fallopian tube
C57.02	Malignant neoplasm of left fallopian tube

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Primary fallopian tube tumors make up 0.3% to 1.1% of all gynecologic cancers.

Highest incidence in white, non-Hispanic women aged 60 to 79 yr.

GENETICS: Patients with BRCA mutations have a 0% to 12% incidence of serous tubal intraepithelial carcinomas (STIC). Women with hereditary nonpolyposis colorectal cancer also have a higher risk of STIC than the general population.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical exam findings are similar to those of ovarian and primary peritoneal cancers. Patients can have abdominal bloating, early satiety, abdominal distention, and weight loss. However, many early fallopian tube cancers are detected at time of risk-reducing bilateral salpingoophorectomy.

ETIOLOGY

Etiology is unknown at this time. STIC is believed to be the precursor lesion to high-grade serous carcinomas (HGSC) of the ovary.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ovarian cancer
- Primary peritoneal cancer

WORKUP

LABORATORY TESTS:

- Complete blood count, basic metabolic panel
- CA125
- Pathology:
  1. Until recently, grossly positive tubal mass was required to assign the tumor origin to the fallopian tube.
  2. Fimbrial carcinoma is unlikely to cause tubal dilation.
  3. More recently the SEE-FIM protocol for pathologic evaluation of fallopian tubes has been used to better evaluate the potential for primary fallopian tube cancers.
  4. SEE-FIM involves sectioning and extensively examining the fimbriated end. Fimbrial carcinoma is unlikely to cause tubal dilation.
  5. Fimbrial carcinomas contain TP53 mutations.

IMAGING STUDIES

- Pelvic ultrasonography
- CT abdomen/pelvis

STAGING

See Table E1.

TREATMENT

Approach mirrors treatment for ovarian cancers

NONPHARMACOLOGIC THERAPY

Surgery: Generally, total hysterectomy with removal of both tube and ovaries is the first-line treatment with goal of complete resection of all visible tumors; pelvic and para-aortic lymph node resection is often also performed.

ACUTE GENERAL Rx

Medications to control nausea and vomiting, constipation associated with tumor burden

CHRONIC Rx

- Adjuvant chemotherapy:
  1. Usually with platinum-based combination chemotherapy regimens, usually platinum-taxane combination
- Radiotherapy is no longer recommended

DISPOSITION

SURVIVAL:

- 5-yr survival is about 65% or higher.
- Stage of disease at time of diagnosis is the most important prognostic indicator.
- Overall survival is 30% to 50%.

AUTHORS: **Emily E. Nuss, MD, Beth Leopold, MD,** and **Anthony Sciscione, DO**

TABLE E1 International Federation of Gynecology and Obstetrics Staging

- **Stage 0.** Carcinoma in situ (limited to tubal mucosa)
- **Stage I.** Growth limited to the fallopian tubes
  1. **Stage I_A.** Growth limited to one tube with extension into submucosa and/or muscularis, but not penetrating the serosal surface. No malignant calls in ascites or peritoneal washings.
  2. **Stage I_B.** Growth limited to both tubes with extension into submucosa and/or muscularis but not penetrating the serosal surface. No malignant calls in ascites or peritoneal washings.
  3. **Stage 1_C.** Tumor either stage I_A or I_B with tumor extension through or onto the tubal serosa OR with ascites containing malignant cells OR with positive peritoneal washings.
- **Stage II.** Growth involving one or both fallopian tubes with pelvic extension.
  1. **Stage II_A.** Extension and/or metastasis to the uterus and/or ovaries
  2. **Stage II_B.** Extension to other pelvic tissues
  3. **Stage II_C.** Tumor either stage II_A or II_B AND with ascites containing malignant cells OR with positive peritoneal washing
- **Stage III.** Tumor involving one or both fallopian tubes with peritoneal implants outside of the pelvis, involvement of the small bowel, omentum, or liver surface, and/or positive retroperitoneal or inguinal nodes. Peritoneal implants are studs of tumors implanted in the abdominal wall
  1. **Stage III_A.** Tumor grossly limited to the true pelvis with negative nodes, but with histologically confirmed microscopic seeding of abdominal peritoneal surfaces (small bowel, omentum, or liver surface)
  2. **Stage III_B.** Tumor involving one or both tubes with histologically confirmed implants visualized on the abdominal peritoneal surfaces (small bowel, omentum, liver surface), none exceeding 2 cm in diameter. Lymph nodes negative for tumor
  3. **Stage III_C.** Abdominal implants greater than 2 cm in diameter and/or positive retroperitoneal or inguinal nodes
- **Stage IV.** Growth invading one or both fallopian tubes with distant metastases, including parenchymal liver metastases. Parenchymal liver disease refers to cancer inside the liver; it differs from disease on the liver surface, which may qualify as stage III disease. Fluid on the lungs (pleural effusion) may classify as stage IV disease, but only if cancer cells are found to be present in the fluid

BASIC INFORMATION

DEFINITION

A fall is an "event which results in a person coming to rest inadvertently on the ground and other than a consequence of the following: loss of consciousness, sudden onset of paralysis, or epileptic seizure."

SYNONYMS

Syncope
Collapse

ICD-10CM CODES	
E880-E888.9	Accidental fall
R29.6	Repeated falls

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Trauma is the fifth leading cause of death in persons >65 yr of age, and falls are responsible for 70% of accidental deaths in persons ≥75 yr.
- The incidence of falls among community-dwelling older adults is 30% to 40%. Two thirds of falls in the community are preventable; 6% to 7% of these falls result in fracture.
- The incidence of falls for nursing home and hospitalized older adults is three times the rate of community-dwelling older adults. Over 50% of nursing home residents fall during their stay.
- 20% to 30% of older adults who fall suffer significant injury leading to immobility, dependence, and an increased risk of early death.

HEALTH CARE COST: In 2006, patients ≥65 had over 2.1 million visits to the ED for injurious falls, which was 10.5% of all ED visits among the elderly and 29.6% of these visits required hospital admission. In those that were admitted, the mean length of stay was 5.5 days with a mean cost of $10,800. The aggregate hospital cost for those requiring admission in 2006 was $6.8 billion. (Source: Healthcare Cost and Utilization Project.)

PREDOMINANT SEX & AGE:

- Fall-related mortality is highest among older white men followed by white women, African American men, and African American women.
- The incidence rates of falls increase with advancing age.
- Older adults ≥85 yr are 10 to 15 times more likely to have a fracture compared with those aged 60 to 65 yr.

RISK FACTORS: Four groups of risk factors for falls have been identified (Table 1):

- Intrinsic factors inherent in the older adult who falls.
- Extrinsic factors circumstantial to the older adult who falls.
- Falls in nursing homes.
- Situational or the activity in which the older adult is engaged in when a fall occurs.

CLINICAL PRESENTATION

- Older adults who fall may present with minor soft tissue injuries, such as lacerations or bruising, hip fracture, or head trauma; however, most falls are not reported unless an injury has occurred.
- If an older adult presents for medical attention for a fall or reports recurrent falls in the past year or difficulties in walking or balance, a multifactorial fall risk assessment should be completed.
- The multifactorial fall risk assessment should include:
  1. Focused history: A detailed history of events and circumstances surrounding fall, relevant risk factors including review of medications, acute and chronic medical problems (e.g., osteoporosis, urinary incontinence, and cardiovascular disease), and whether the fall was witnessed
  2. Physical examination:
     a. Vital signs including orthostatics.
     b. Cardiovascular examination assessing for arrhythmias, carotid bruits, or new murmurs.
     c. Neurologic examination including vision assessment, evaluation of lower-extremity strength, peripheral nerves, proprioception, and testing of cortical, extrapyramidal, and cerebellar function.
     d. Gait and balance assessment: Multiple screening tools are available for fall risk screening and balance assessment (Tables 2 and 3). "Get up and go test" is a rapid assessment that will quickly tell you if the patient needs rehabilitation and what to work on. (Ask patient to stand from a seated position without use of hands, walk 10 feet forward, turn around, and return to chair and sit).
     e. Musculoskeletal exam with attention to joints of lower extremity, feet, and footwear.
  3. Functional assessment including the older adult's activities of daily living skills, use of adaptive equipment, and fear of falling
  4. Environmental assessment of home safety

TABLE 1 Risk Factors for Falls in the Elderly

Intrinsic

Aging

Age-related decline in vestibular function might lead to loss of balance, dizziness, and falls. Aging of the vision system (e.g., glaucoma, cataracts, retinopathy) may result in decreased visual acuity, inability to discriminate dark/light, and decreased spatial perception.

Cardiac

Cardiac arrhythmias, carotid sinus hypersensitivity, neurocardiogenic syncope.

Neurologic

Parkinson disease, normal pressure hydrocephalus (NPH), sensory neuropathy, dementia/impaired cognition, cervical myelopathy, senile gait disorder, prior stroke. (One third of the elderly have abnormal position sense.)

Musculoskeletal

Lower extremity weakness, impaired knee extension and ankle plantar flexion strength contribute to abnormalities in gait velocity and step length, deconditioning, arthritis, foot abnormalities (such as bunions, calluses, or nail abnormalities).

Vascular

Vertebrobasilar insufficiency, postural hypotension, postprandial hypotension.

Metabolic

Hypoglycemia, hypothyroidism, hyponatremia.

Psychiatric

Depression.

Medications

Use of more than four medications may be associated with an increased risk of falls. Medications that may increase fall risk include benzodiazepines, sleeping medications, neuroleptics, antidepressants, anticonvulsants, class I antiarrhythmics, and antihypertensives.

Extrinsic

Environmental

Environmental hazards cause >50% of falls in the elderly (cords, furniture, small objects, ill-fitting shoes, slippery surfaces, loose rugs, uneven steps, optical patterns on escalators). Majority occurs with mild-moderate activity (walking, stepping up/down, changing position); 70% occur at home and 10% on stairs (descending > ascending).

Nursing Home Falls

20% have a cardiovascular cause (hypotension: drug induced, postprandial, postural, or bradycardia) 5% are the result of an acute illness such as PNA, febrile illness, UTI, CHF.

3% are from an overwhelming intrinsic event such as syncope, seizure, stroke, psychoactive drugs.

Situational

Tripping over obstacles, carrying heavy items, descending/ascending stairs, rapid turning, reaching overhead, climbing ladders, ill-fitting shoes, lack of assistive devices.

CHF, Congestive heart failure; *PNA,* pneumonia; *UTI,* urinary tract infection.

TABLE 2 Scales Used for Fall Risk Screening and Balance Assessment

Instrument	Items	Setting		
		Community	Acute	Chronic
Multifactorial Reports				
STRATIFY	Five items—history of falls, agitation, visual impairment, frequent toileting, able to stand but needs assistance with moving		X	X
Morse Fall Scale	Six items—history of falls, secondary diagnoses, parenteral therapy, use of ambulation aids, gait, mental status		X	X
FROP-Com	13 risk factors in 26 items—fall and fall injury history, medications, medical conditions, sensory loss, feet, cognitive status, toileting, nutrition, environment, function, behavior, balance, gait; total score, 0 to 60; fall risk high with score >24	X		
Fall risk for residential care	Among persons who can stand without assistance—poor balance or two of three the following: Fall history, nursing home residence, urinary incontinence Among persons who cannot stand without assistance—one of three of the following: fall history, hostel residence, use of nine or more medications			X
Functional Mobility				
Berg Balance test	14 tasks scored 0 to 4; total range 0 to 56; fall risk increases as score decreases	X	X	X
Functional reach	Distance reached in inches without moving the feet; fall risk <7 inches	X	X	X
Performance-oriented mobility and balance	Balance subscale score 0 to 16, gait subscale 0 to 12, summary score 0 to 28; summary score <19 indicates high fall risk	X		X
Timed up and go	Time in seconds to rise from a chair, walk 3 m, turn, walk back, and sit down; <10 sec normal; fall risk increases with time >13.5 sec	X		X
Dynamic gait index	Eight walking tasks scored 0 to 3, total score 0 to 24; <18 or 19 indicates fall risk	X		
Functional mobility tests	Time to complete eight step ups (alternate step test) >10 sec, timed sit to stand five times >12 sec, 6-m walk time >6 sec increased fall risk	X		
Physiologic profile assessment	Performance in five domains: Sway, reaction time, strength, proprioception, contrast sensitivity; total score 0 to >3; fall risk increased with score ≥2	X		

FROP-Com, Falls Risk for Older People in the Community; *STRATIFY,* St. Thomas Risk Assessment Tool in Falling elderly inpatients.
From Fillit HM et al: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

TABLE 3 Clinical Assessment Based on Components of Postural Control

Organ System	Impairment	Clinical Evaluation	Potential Cause
Eye	Decreased acuity	Vision chart	Presbyopia, macular degeneration, cataracts
	Reduced visual fields	Confrontation, perimetry	Glaucoma, posterior circulation stroke
	Decreased depth perception	Stereo or depth testing	Monocular vision
	Decreased dark adaptation	Self-report—inability to dilate pupil in low light	Aging, miotic agents for glaucoma
Vestibular apparatus	Otoliths	Ability to detect true vertical, Hallpike maneuver	Benign positional vertigo
	Semicircular canals	Ability to detect position during rotation with eyes closed, nystagmus, visual acuity during head motion	Meniere disease, vestibular hypofunction
Peripheral nerve	Peripheral neuropathy	Light touch, filaments, two-point discrimination, vibratory sense	Diabetes, peripheral vascular disease, vitamin B_{12} deficiency
Circulation	Reduced cerebral perfusion	Low blood pressure, altered level of consciousness, light-headedness	Medications, arrhythmias, postprandial hypotension
	Orthostatic hypotension	Positional change in blood pressure	Medications, autonomic dysfunction, dehydration
Brain	Reduced attention	Ability to perform dual tasks like timed up and go with cup of water, executive function tasks	Mild cognitive impairment, dementia, medications
	Psychomotor slowing	Timed tapping, timed finger to nose test, trails A test (connect the dots)	Medications, degenerative and vascular brain diseases
	Altered postural reflexes	Absent or slowed righting reflexes	Parkinson disease, other extrapyramidal and degenerative brain diseases
Muscle	Reduced strength	Manual muscle testing, strength-based functional performance (chair rise, squat)	Generalized—inactivity, sarcopenia, vitamin D deficiency, myopathies
			Focal deficits, spinal cord and peripheral motor nerve conditions
Musculoskeletal pain	Loss of flexibility	Contractures, decreased range of motion	Arthritis, inactivity
	Bone and joint deficits	Weight-bearing pain	Arthritis, fractures, periarticular conditions, foot problems
	Disturbance of spinal cord, roots, nerves	Leg and back pain with activity	Spinal stenosis, radiculopathies, peripheral neuropathies

From Fillit HM et al: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

ETIOLOGY

- Falls are a multifactorial syndrome resulting from the cumulative effects of impaired gait and balance, aging, polypharmacy, depression, cognitive impairment, acute medical illness, or environmental factors (Fig. E1).
- Most falls among community-dwelling older adults are due to environmental factors, whereas falls among nursing home residents are a result of confusion, gait impairment, or postural hypotension.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Falls are often a nonspecific symptom of an acute illness (such as delirium, urinary tract infection, acute anemia, or pneumonia) or an exacerbation of a chronic disease (chronic heart failure [CHF] or chronic obstructive pulmonary disease [COPD]). The mnemonic "DELIRIUMS" can be used to assess the differential diagnosis in acute delirium. (**D**rugs, **E**motional [depression], **L**ow PaO_2 [CHF, COPD], **I**nfection, **R**etention [urinary, fecal], **I**ctal status, **U**nder nutrition/hydration, **M**etabolic, **S**ubdural/Sensory [all neurologic causes] workup).

WORKUP

- Older adults presenting with a noninjurious fall need a detailed history and physical exam to identify acute medical illnesses and potential modifiable risk factors. Laboratory and neuroimaging studies may be necessary if the history and physical exam indicate a specific problem. ECG and Holter monitoring may be considered if cardiac arrhythmia is suspected.
- See Fig. E1.

LABORATORY TESTS

CBC, stool guaiac, blood chemistries, thyroid function, liver function, vitamin B_{12} level, folate level, erythrocyte sedimentation rate, vitamin D level, drug levels, and urinalysis depending on physical/historical findings.

IMAGING STUDIES

- CT or MRI of the brain or cervical spine films in the presence of neurologic or gait impairment.
- Chest x-ray if pulmonary pathology (pneumonia, pulmonary edema) is suspected.
- Consider ECG, echocardiography, or Holter monitor if suspicious for structural cardiac abnormality or syncope.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Physical therapy evaluation for gait and balance training, evaluation of appropriate assisted devices (e.g., cane, walker), the use of fall prevention equipment (e.g., low beds, bed alarms).
- Home safety assessment: Studies show that 50% of recurrent fallers fell doing the same activity that caused them to fall the first time. This can be prevented by creating a home safety evaluation checklist (preferably done by family member to improve compliance) or arranging for a home safety inspection by a visiting nurse or occupational therapist.
- Minimization or discontinuation of certain medications associated with falls (psychotropics).
- Customized exercise program to improve strength, gait, and balance.
- Evaluation of proper footwear, hard sole, and low heel height.

ACUTE GENERAL Rx

Hospitalization may be necessary for treatment of hip fracture, subdural hematoma, lacerations, or trauma as well as the treatment of underlying cause of the fall such as infection, metabolic disturbances, cardiovascular (e.g., carotid sinus hypersensitivity, vasovagal syndrome, bradyarrhythmias, and tachyarrhythmias) or neurologic abnormality.

CHRONIC Rx

- Screen and treat for osteoporosis as low bone density increases the risk of hip or other fractures.
- Optimize treatment of chronic illnesses such as CHF, COPD, osteoarthritis, Parkinson disease, dementia, postural hypotension, and visual problems.
- Vitamin D supplementation of at least 800 IU per day. Epidemiological studies reveal that compared with usual care, short-term intervention with oral nutritional supplementation and dietetic counseling significantly decrease falls in malnourished older adults.
- Table 4 summarizes the management of impairments that contribute to instability and falls.

COMPLEMENTARY & ALTERNATIVE MEDICINE

T'ai chi has been shown to reduce the risk of falls in community-dwelling study participants.

DISPOSITION

Falls increase the older adult's risk of hospitalization, institutionalization, and mortality.

REFERRAL

- Referral may be appropriate to cardiologist, ophthalmologist, neurologist, or podiatrist depending on the presence of a specific condition.
- Consider referral to physical therapist for gait and balance training, evaluation for assisted device, or strengthening program.

PEARLS & CONSIDERATIONS

COMMENTS

- Fear of falling may lead to restriction of activities, social isolation, and dependence.
- Older adults with four or more risk factors have a 78% chance of falling.
- Mortality from falls has increased by 42% over the past decade.

PREVENTION

The U.S. Preventive Services Task Force recommends exercise or physical therapy and vitamin D supplementation to prevent falls in community-dwelling adults aged ≥65 who are at increased risk for falls. It does not recommend automatically performing an in-depth multifactorial risk assessment in conjunction with comprehensive management of identified risks to prevent falls in community-dwelling adults aged 65 or older because the likelihood of benefit is small. In determining whether this service is appropriate in individual cases, patients and clinicians should consider the balance of benefits and harms on the basis of the circumstances of prior falls, comorbid medical conditions, and patient values.

SCREENING

The "get up and go test" is a quick assessment of balance and gait. A more in-depth screening tool for falls is the Tinetti gait and balance assessment, which evaluates normal and adaptive ability to maintain balance when rising from a chair, standing with eyes closed, turning, and receiving a sternal nudge. It also evaluates several components of gait (step height, postural sway, path deviation). The test is scored on the patient's ability to perform specific tasks. Scoring is done on a 3-point scale with a range of 0 to 2. Individual scores are combined to form three measures: an overall gait assessment score (maximum score = 12), an overall balance assessment score (maximum score = 16), and a gait and balance score (maximum score = 28). In general, patients who score below 19 are at high risk for falls, and those who score 19 to 24 are at risk for falls.

PATIENT & FAMILY EDUCATION

Providing education and information for the patient and caregiver regarding fall prevention strategies in addition to multifactorial risk reduction strategies

AUTHORS: **Sean H. Uiterwyk, MD, Alicia J. Curtin, PhD,** and **Keith Brennan, MD**

TABLE 4 Management of Impairments That Contribute to Instability and Falls

Organ System	Impairment	Medical Management	Restorative Services	Environmental Modifications
Eye	Decreased acuity	Corrective lenses	Low vision rehabilitation	Lighting
	Reduced visual fields	Prisms in spectacles	Low vision rehabilitation, teach to scan using head rotation	
	Loss of depth perception	Cataract removal, if indicated	Teach to use shadows to detect depth	Lighting to accent shadows, contrast
	Poor dark adaptation	Switching to glaucoma medications that do not cause miosis		Lighting
Vestibular system	Benign paroxysmal positional vertigo (BPPV)	Epley maneuver	Vestibular rehabilitation	
	Meniere disease	Cautious use of meclizine, diuretics; rarely, surgery	Vestibular rehabilitation	
Peripheral nerve	Neuropathy	Footwear to protect foot and maximize sensation	Assistive devices for haptic enhancement	Hand holds, railings
Central circulation	Reduced brain perfusion	Treatment varies by cause Arrhythmias—medications to control rate and rhythm, pacemakers Postprandial hypotension—frequent small meals		
	Orthostatic hypotension	Treatment varies by cause Adjust offending medications Autonomic neuropathy—salt loading, fluorinated corticosteroids Dehydration—hydration, reduce diuretic dose	Compression hose, calf muscle contractions	
Brain	Reduced attention	Medication adjustment	Practice dual tasks	
	Psychomotor slowing	Medication adjustment	Practice movement speed	
	Abnormal righting reflexes	Antiparkinsonian medication helps bradykinesia more than balance	Assistive devices, practice getting up after a fall	Protective clothing
Effector muscle	Weakness	Reduced activity—treat contributing causes (e.g., CHF, anemia, COPD, arthritis)	Strength-training exercises	Raise chair height
		Focal motor deficit due to spinal stenosis—sometimes surgery Myopathy—adjust offending medications, possibly steroids for myositis	Orthotics, exercise, assistive devices	
Musculoskeletal	Decreased range of m motion		Active and passive range of motion exercise, orthotics	
Pain	Bone and joint	Analgesics, injections	Physical modalities (e.g., heat, massage, assistive devices, orthoses, adaptive equipment)	Place items within easy reach
	Spinal cord, roots, nerves	Injections, surgery, analgesics	Orthoses, assistive devices	Place items within easy reach

Familial Adenomatous Polyposis and Gardner Syndrome PTG

BASIC INFORMATION

DEFINITION

Familial adenomatous polyposis (FAP) is a highly penetrant, autosomal-dominant condition characterized by hundreds of colorectal adenomatous polyps that inevitably progress to cancer (Fig. E1). *Gardner syndrome* is a subset of FAP, with prominent extraintestinal manifestations including dental abnormalities, soft tissue lesions, desmoid tumors, and osteomas.

ICD-10CM CODES

D12.2 Benign neoplasm of ascending colon
D12.3 Benign neoplasm of transverse colon
D12.4 Benign neoplasm of descending colon
D12.5 Benign neoplasm of sigmoid colon
D12.6 Benign neoplasm of colon, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- FAP occurs in approximately 1 in 10,000 births worldwide.
- FAP accounts for <1% of all colorectal cancers.
- Individuals develop hundreds to thousands of adenomatous colorectal polyps.
- Polyps usually present in adolescence.
- 100% lifetime risk for colorectal cancer; most diagnosed by 40 yr of age.
- Gastric, duodenal, periampullary, and small bowel polyps occur but have lower malignant potential.
- Increased risk for other tumors: Desmoid (15%), duodenal/periampullary (7%), thyroid (2%), brain (1%), childhood hepatoblastoma (1%), nasopharyngeal angiofibroma (benign), pancreatic (2%), adrenal adenoma (10%), and gastric (1%).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Phenotypic variability is seen in individuals and families with the same mutation. Extraintestinal manifestations may precede intestinal disease. These findings are reported in at least 20% of individuals with FAP.

- Congenital hypertrophy of the retinal pigment epithelium (CHRPE): Benign fundus lesions, usually present at birth
- Dental abnormalities: Supernumerary or unerupted teeth
- Soft tissue lesions: Epidermal or sebaceous cysts, fibromas, lipomas, desmoid tumors (benign, locally invasive, aggressive connective tissue tumor)
- Osteomas (benign bone growths): Skull, mandible, long bone
- Anemia, occult blood in stool, bowel obstruction, weight loss

ETIOLOGY

- FAP is caused by mutations of the tumor suppressor gene adenomatous polyposis coli *(APC)* on chromosome 5q21 to q22; more than 1000 disease-causing mutations identified. The site of the mutation often correlates with the extraintestinal findings.
- De novo mutations are responsible for approximately 20% of FAP cases. These may be due to germline mutations or somatic cell mosaicism, which is seen when a new mutation occurs in the APC gene post-fertilization and is present in only a subset of cell types or tissues.
- Table E1 summarizes the genetics of colonic polyposis.

DIAGNOSIS

In individuals with a family history, more than 100 adenomatous colorectal polyps, CHRPE lesions, or positive genetic testing confirms diagnosis. In those without a family history, more than 100 adenomatous colorectal polyps suggest the diagnosis, and genetic testing confirms it. The diagnosis should be considered in individuals with ≥10 adenomatous colorectal polyps or fewer polys in the presence of extraintestinal findings.

DIFFERENTIAL DIAGNOSIS

- Turcot syndrome
- Attenuated FAP (also APC gene mutation, but presents with fewer polyps [<100], at a later age, and has lower cancer risk than FAP [~80% lifetime risk])
- MUTYH-associated polyposis
- Peutz-Jeghers syndrome
- Juvenile polyposis syndrome
- Cowden disease
- Lynch syndrome
- Hereditary mixed polyposis syndrome
- Polymerase proofreading-associated polyposis
- Hyperplastic polyposis
- Table 2 compares various adenomatous polyposis syndromes

WORKUP

History, physical examination, laboratory tests, imaging studies

DIAGNOSTIC SCREENING OPTIONS

GENETIC TESTING: NOTE: Genetic counseling should be performed, and written informed consent obtained before testing. Refer to a specialized center for counseling and evaluation.

- Should be offered to first-degree relatives of affected individuals (with an identified mutation) at age 10 to 12 yr and clinically suspected individuals.
- Able to identify a mutation in approximately 80% of families. To ensure that the family has a detectable mutation, test an affected family member first.
- If positive in the affected individual, the test can differentiate with 100% accuracy affected and unaffected family members. If negative in the affected individual, screening family members will not be useful in determining disease status.
- If no known family history exists, screening the clinically suspected individual is reasonable. A positive test rules in FAP but a negative test does not rule it out.
- Numerous testing techniques available; may require multiple tests to identify the mutation.

SIGMOIDOSCOPY:

- Individuals with a positive genetic test, untested at-risk family members, or patients from families with an unidentified *APC* mutation: Annual flexible sigmoidoscopy or colonoscopy beginning at 10 to 12 yr of age.
- Once adenomatous polyps are detected, patients should undergo colonoscopy and evaluation for colectomy.
- Negative genetic test in patients from families with an identified mutation: Average risk screening.
- Screening with upper endoscopy should begin at age 25 and should include visualization of duodenal papilla. Additional annual screening should include thyroid ultrasound.

CHRPE: Lesions occur in up to 80% of families and are a reliable indicator of affected status in these families.

TREATMENT

- Prophylactic colectomy or proctocolectomy: Timing determined by polyp number, size, and degree of dysplasia. Postsurgical endoscopic surveillance annually.
- Additional screening:
  1. Annual physical examination: History, examination (including thyroid), and blood tests
  2. Upper endoscopy to screen for gastric/duodenal polyps: Baseline at age 25 yr (earlier if colon polyps detected) and repeated every 3 mo to 4 yr based on findings
  3. Annual thyroid ultrasound: Begin in teenage yrs
  4. Other possible cancer sites imaged if symptoms occur or if these cancers have occurred in relatives
- Treat soft tissue lesions and osteomas for symptoms or cosmetic concerns. Treat desmoid tumors if they pose a risk to adjacent structures.

DISPOSITION

- 100% chance of colorectal cancer in untreated individuals. Many other neoplasms occur at higher rates.
- Metastatic colorectal cancer is the leading cause of death (58%), followed by desmoid tumors (11%), and duodenal/periampullary adenocarcinoma (8%).

REFERRAL

- Patients should be managed at centers with expertise in FAP, including a gastroenterologist, medical geneticist, and surgeon.
- Genetic counselors can be found at www.nsgc.org.
- Genetic clinics and laboratories can be found at www.ncbi.nlm.nih.gov/gtr.

TABLE 2 Adenomatous Polyposis Syndromes

Syndrome	Gene Mutation	Polyps	Extraintestinal Abnormalities
Classic FAP	*APC* (usually truncated protein)	Colonic adenomas (thousands) Duodenal, periampullary adenomas Gastric fundic gland polyps Jejunal and ileal adenomas Ileal lymphoid polyps	Mandibular osteomas Dental abnormalities
Gardner variant of FAP	*APC*	Same as FAP	Osteomas (mandible, skull, long bones) CHRPE Desmoid tumors Epidermoid and sebaceous cysts Fibromas, lipomas Thyroid, adrenal tumors
Turcot variant of FAP	*APC* DNA MMR*	Colonic adenomas (sometimes fewer than in classic FAP)	Medulloblastoma Glioblastoma multiforme CHRPE
Attenuated FAP	*APC* 5′ and 3′ regions	Colonic adenomas (<100; proximal colon) Duodenal, periampullary adenomas Gastric fundic gland polyps	Mandibular osteomas (rare)
Familial tooth agenesis	*Axin2* (APC pathway)	Colonic adenomas Hyperplastic polyps	Agenesis of teeth
Bloom syndrome	*BLM*	Colonic adenomas	Small stature Facial erythema/telangiectasia Male sterility Adenocarcinomas, leukemia, lymphoma
MUTYH polyposis	*MUTYH (MYH)*	Colonic adenomas (5-100) Duodenal polyposis Gastric cancer	CHRPE Osteomas

*May be more appropriately classified under hereditary nonpolyposis colon cancer.
APC, Adenomatous polyposis coli; *CHRPE,* congenital hypertrophy of the retinal pigment epithelium; *DNA,* deoxyribonucleic acid; *FAP,* familial adenomatous polyposis; *MMR,* mismatch repair.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.

PEARLS & CONSIDERATIONS

- Management should be individualized based on genotype, phenotype, and individual preferences.
- Sulindac (NSAID) and celecoxib (COX-2 inhibitor) can cause duodenal and colorectal polyp regression in individuals with FAP. Preliminary studies with other agents also show polyp regression. Their ability to reduce cancer risk remains unknown; they do not replace colon resection for cancer prevention.
- Desmoid tumors usually present in the 30s, frequently occur in the abdomen, and are difficult to treat with high rates of recurrence. Growth and recurrence are stimulated by surgery.
- Screen children of affected parents (from infancy to age 7 yr) biannually with alpha-fetoprotein level and liver ultrasound to rule out hepatoblastoma.
- Preimplantation and prenatal genetic testing is available.

Familial Mediterranean Fever (FMF)

BASIC INFORMATION

DEFINITION

Familial Mediterranean fever (FMF) is a hereditary periodic fever syndrome. FMF type 1 is characterized by recurrent short episodes of inflammation and serositis, while FMF type 2 is characterized by amyloidosis as the first clinical manifestation.

SYNONYMS

Non-neuropathic heredofamilial amyloidosis
Benign paroxysmal peritonitis
Familial paroxysmal polyserositis
Recurrent polyserositis
Periodic fever
FMF

ICD-10CM CODE

E85.0 Non-neuropathic heredofamilial amyloidosis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Varies depending on the ethnic background of the population. FMF affects primarily eastern Mediterranean populations (e.g., Armenian, Arab, Turkish, Jewish) but is not restricted to these ethnic groups. In Armenians, the prevalence is 1 in 500, and in people of Turkish descent, estimates are 1 per 1000. As many as 1 in 5 people of these ethnic backgrounds is a carrier of FMF.
PREDOMINANT SEX AND AGE: Male:female ratio is 1.5 to 2:1. Disease onset is typically before age 20, with the vast majority of initial attacks occurring before age 10. Very rare to have onset after age 40.
GENETICS: Pattern of inheritance is primarily autosomal recessive. Mutations in the *MEFV* gene, which encodes the pyrin protein, causes the disease in many cases. There are more than 80 known mutations, and in 10% to 20% of cases no mutation is found, although FMF diagnostic criteria fulfilled.
RISK FACTORS: Affected first-degree relatives, consider offering genetic testing

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Sporadic, recurrent attacks of fever and severe pain, abrupt in onset, usually lasting 1 to 3 days, with spontaneous resolution.
- Almost all patients have episodic abdominal pain. On exam may have tenderness, guarding, rebound and rigidity; may be mistaken for an acute surgical abdomen.
- Attacks localized to chest in up to half of patients due to pleural inflammation or referred from subdiaphragmatic inflammation.
- Arthritis is usually mono- or oligoarticular, involving large joints (e.g., knee, ankle, hip). Pain is usually out of proportion to swelling.
- Up to 50% of patients can have an erysipelas-like rash, usually on lower extremities (Fig. E1).
- Rarer manifestations include prolonged febrile myalgias, pericarditis, orchitis, aseptic meningitis, migratory polyarthritis, Henoch-Schönlein purpura, sacroiliitis, infertility.

ETIOLOGY

MEFV is the only gene in which pathogenic variants are known to cause FMF, and it encodes pyrin, a protein that plays a role in the innate immune system and helps regulate the inflammasome. The exact mechanism that triggers acute FMF attacks remains unclear.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other periodic fever syndromes (Table E1)
- Systemic rheumatic diseases (e.g., rheumatoid arthritis, systemic lupus erythematosus, adult onset Still disease, abdominal vasculitis)
- Infection

WORKUP

The diagnosis is based on a detailed history with suggestive clinical symptoms and is supported by ethnic origin and family history; the diagnosis is not excluded by negative genetic testing. If genetic testing is negative but clinical suspicion remains high, can consider trial of colchicine; would expect a favorable response.

LABORATORY TESTS

- CBC: Leukocytosis with neutrophil predominance
- Elevated acute phase reactants: erythrocyte sedimentation rate, c-reactive protein, fibrinogen, serum amyloid A protein
- Sterile, inflammatory synovial fluid if arthrocentesis conducted
- Urinalysis with proteinuria should raise concern for renal amyloidosis
- *MEFV* gene mutation (75% are V726A, M694V, M694I, M680I, E148Q)
- If undergoing abdominal surgery, a negative laparotomy is expected

FIG. E1 Familial Mediterranean fever rash. A, Erysipelas-like erythema (ELE) of familial Mediterranean fever (FMF): erythematous plaques on the foot. **B,** ELE of FMF: erythematous plaques on the lower extremity. (From Callen JP et al: *Dermatologic signs of systemic disease,* ed 5, 2017, Elsevier.)

TABLE E1 Hereditary Periodic Fever Syndromes

	Hereditary Periodic Fever Syndromes					
				Cryopyrin-associated periodic syndromes (CAPS)		
	FMF	**HIDS**	**TRAPS***	**MWS**	**FCAS† (1 and 2)**	**NOMID (CINCA)**
Ethnicity	Sephardic Jewish, Arab, Turkish, Italian, Armenian	Predominantly Dutch, Northern European	Any ethnic group	Any ethnic group	Any ethnic group	Any ethnic group
Inheritance	AR	AR	AD	AD	AD	AD
Gene	*MEFV*	*MVK* ‡	*TNFRSF1A*	*NLRP3 (CIAS1)*	*NLRP3 (CIAS1); NLRP12*	*NLRP3 (CIAS1)*
Chromosome	16p13.3	12q24	12p13	1q44	1q44	1q44
Protein	Pyrin	Mevalonate kinase	TNF receptor-1A	Cryopyrin	Cryopyrin; monarch-1	Cryopyrin
Attack length	1-3 days	3-7 days	Often >7 days	1-2 days	Minutes – 3 days	Continuous + flares
Mucocutaneous lesions	Erysipeloid erythema and edema	Erythematous macules and edematous papules, which may become purpuric; occasional oral and vaginal ulcers	Erythematous patches and edematous plaques (often annular or serpiginous); later ecchymotic in appearance; rarely oral ulcers	Urticarial papules and plaques	Cold-induced urticarial papules and plaques	Urticarial papules and plaques; occasional oral ulcers
Distribution of skin lesions	Favor lower leg, foot	Widespread on face, trunk, and extremities	Migrate distally on an extremity with underlying myalgia; may be more widespread	Widespread on face, trunk, and extremities	Extremities > trunk, face	Widespread on face, trunk, and extremities
Abdominal pain and serositis	Peritonitis > pleuritis > pericarditis	Abdominal pain, but rarely serositis	Peritonitis > pleuritis, pericarditis	Abdominal pain, but rarely serositis	Rare	Rare
Musculoskeletal findings	Monoarthritis > exercise-induced myalgia	Arthralgia > oligoarticular arthritis > myalgia	Migratory myalgia > arthralgia > monoarthritis	Myalgia ("lancinating limb pain"), arthralgia > large-joint oligoarticular arthritis	Arthralgia > myalgia	Epiphyseal and patellar overgrowth, arthritis, deforming arthropathy
Ocular findings	Uncommon	Uncommon	Periorbital edema, conjunctivitis, rarely uveitis	Conjunctivitis, episcleritis, optic disc edema	Conjunctivitis	Conjunctivitis, uveitis, optic disc edema, blindness
Neurologic findings	Rarely aseptic meningitis	Headache	Headache	Sensorineural hearing loss; headache	Headache	Sensorineural hearing loss; aseptic meningitis, seizures
Other clinical findings	Acute scrotal swelling; splenomegaly	Cervical LAN, HSM	Scrotal pain; splenomegaly, occasional LAN			LAN, HSM; dysmorphic facies—frontal bossing, protruding eyes
Amyloidosis	Most common in M694V homozygotes	Rare	~15% of cases	~25% of cases	Uncommon	Late complication
Dermal infiltrate in typical skin lesions	Neutrophils	Neutrophils and/or lymphocytes; mild vasculitis common	Lymphocytes, monocytes, and a few neutrophils	Neutrophils and/or lymphocytes (sparse)	Neutrophils (perivascular)	Neutrophils (perivascular + periadnexal)
Cutaneous vasculitis	LCV/HSP (5%-10%), PAN (~1%)	LCV/HSP	Lymphocytic small vessel (rare)			

TABLE E1 Hereditary Periodic Fever Syndromes—cont'd

	Hereditary Periodic Fever Syndromes					
				Cryopyrin-associated periodic syndromes (CAPS)

Laboratory abnormalities§	Low C5a inhibitor in serosal fluids	High serum IgD‖ (>100 IU/ml) and IgA1; mevalonate in urine during attacks; low lymphocyte mevalonate kinase	Low serum soluble TNF receptor-1 (<1 ng/ml between attacks)			
Treatment	Colchicine prophylaxis; NSAIDs, TNF inhibitors, thalidomide, herbal remedies	Corticosteroids for acute attacks; anakinra; TNF inhibitors (e.g., etanercept); simvastatin	Corticosteroids; TNF inhibitors (e.g., etanercept)	Corticosteroids; IL-1/IL-1R antagonists: rilonacept, canakinumab, anakinra	IL-1/IL-1R antagonists	IL-1/IL-1R antagonists

AD, Autosomal dominant; *AR*, autosomal recessive; *CINCA*, chronic infantile neurologic, cutaneous, and articular syndrome; *FCAS*, familial cold autoinflammatory syndrome; *FMF*, familial Mediterranean fever; *HIDS*, hyperimmunoglobulinemia D with periodic fever syndrome; *HSM*, hepatosplenomegaly; *HSP*, Henoch-Schönlein purpura; *Ig*, immunoglobulin; *IL*, interleukin; *LAN*, lymphadenopathy; *LCV*, leukocytoclastic vasculitis; *MWS*, Muckle–Wells syndrome; *NOMID*, neonatal-onset multisystem inflammatory disease; *NSAID*, nonsteroidal antiinflammatory drug; *PAN*, polyarteritis nodosa; *TNF*, tumor necrosis factor; *TRAPS*, TNF receptor-associated periodic syndrome.
*Includes familial Hibernian fever.
†Also referred to as familial cold urticaria.
‡Allelic with mevalonic aciduria, which is characterized by dysmorphology, psychomotor retardation, and progressive cerebellar ataxia as well as periodic fevers and other features of HIDS.
§Genetic analysis can be performed to confirm the diagnosis.
‖IgD levels are occasionally normal; elevated IgD may also be observed in FMF and TRAPS.
Courtesy, Julie V Schaffer, M.D. In Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

IMAGING STUDIES

During an acute attack, depending on manifestations such as peritonitis, pleuritis, or arthritis, may see air-fluid levels, pleural effusions, and/or synovial effusions.

Rx TREATMENT

The main goals of treatment are to (1) prevent acute attacks and (2) prevent the development of amyloidosis.

ACUTE GENERAL AND CHRONIC Rx

- Supportive care during acute episodes with IVF, NSAIDs, pain control.
- To prevent attacks first-line Rx is colchicine, 0.6 to 1.8 mg daily.
  1. If colchicine unresponsive, possibility of noncompliance, or reconsider diagnosis.
  2. Should continue colchicine in pregnant FMF patients, and it is safe to breastfeed.
- If truly colchicine unresponsive, IL-1 inhibition (anakinra, rilonacept, canakinumab) is second-line; 5% to 10% of patients are colchicine resistant. There are also successful reports of using thalidomide, TNF inhibitors, and tocilizumab.

DISPOSITION

Since the usage of colchicine, most treated patients are asymptomatic and do not commonly see development of AA amyloidosis.

REFERRAL

Rheumatology

PEARLS & CONSIDERATIONS

COMMENTS

- Most patients have disease onset before age 20, and attacks typically last 1 to 3 days. Colchicine is the standard of care for prophylaxis of attacks and prevention of amyloidosis. Should continue treatment with colchicine during pregnancy. Should question diagnosis if there is no response to colchicine. Type AA amyloidosis is the most frequent complication of FMF, with the kidneys being the most affected organ.
- Contrary to expectations, the incidence of cancer in patients with FMF is significantly lower than the general population.

PREVENTION

Should consider referring all first-degree relatives of FMF patients for genetic testing, whether or not they have symptoms.

Fatty Liver of Pregnancy, Acute

BASIC INFORMATION

DEFINITION

Acute fatty liver of pregnancy (AFLP) is characterized histologically by microvesicular fatty cytoplasmic infiltration of hepatocytes with minimal hepatocellular necrosis.

SYNONYMS

Acute fatty metamorphosis
Acute yellow atrophy
AFLP
Acute fatty liver of pregnancy

ICD-10CM CODES

026.611	Liver and biliary tract disorders in pregnancy, first trimester
026.612	Liver and biliary tract disorders in pregnancy, second trimester
026.613	Liver and biliary tract disorders in pregnancy, third trimester
026.619	Liver and biliary tract disorders in pregnancy, unspecified trimester

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Rare: 1 in 10,000 to 1 in 20,000 pregnancies
- Equal frequencies in all races and at all maternal ages

AVERAGE GESTATIONAL AGE: 37 wk (range 28 to 42 wk)

- 20% present postnatally

RISK FACTORS:

- Primiparity
- Multiple gestation
- Male fetus
- History of type 2 diabetes mellitus
- Preeclampsia

GENETICS: Some with a familial deficiency of long-chain 3-hydroxyacyl-coenzyme A dehydrogenase (LCHAD)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Initial manifestations:
  1. Nausea and vomiting (70%)
  2. Pain in right upper quadrant or epigastrium (50% to 80%)
  3. Malaise and anorexia
- Jaundice often in 1 to 2 wk
- Hypoglycemia
- Late manifestations:
  1. Fulminant hepatic failure
  2. Encephalopathy
  3. Renal failure
  4. Pancreatitis
  5. Gastrointestinal and uterine bleeding
  6. Disseminated intravascular coagulation (10%)
  7. Seizures
  8. Coma
- Liver:
  1. Usually small
  2. Normal or enlarged in preeclampsia, eclampsia, HELLP syndrome (hemolysis, elevated liver enzymes, and low platelets), and acute hepatitis
  3. Coexistent preeclampsia in up to 46% of patients

ETIOLOGY

- Fetal long-chain L-3 hydroxyacyl-CoA dehydrogenase deficiency (LCHAD) deficiency results in transplacental passage of excess fetal fatty acids and subsequent accumulation in the maternal liver.
- Postulated that inhibition of mitochondrial oxidation of fatty acids may lead to microvesicular fatty infiltration of liver.
- Fatty metamorphosis of preeclamptic liver disease believed to be of different etiology.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute gastroenteritis
- Preeclampsia or eclampsia with liver involvement
- HELLP syndrome
- Acute viral hepatitis
- Fulminant hepatitis
- Drug-induced hepatitis caused by halothane, phenytoin, methyldopa, isoniazid, hydrochlorothiazide, or tetracycline
- Intrahepatic cholestasis of pregnancy
- Gallbladder disease
- Reye syndrome
- Hemolytic-uremic syndrome
- Budd-Chiari syndrome
- Systemic lupus erythematosus

WORKUP

- A clinical diagnosis is based predominantly on physical and laboratory findings (Swansea criteria).
- Most definitive diagnosis is through liver biopsy with oil red O staining and electron microscopy.
- Liver biopsy is reserved for atypical cases only and only after any existing coagulopathy is corrected with fresh frozen plasma because of concerns for excessive bleeding.

LABORATORY TESTS

Tests to determine the following:

- Hypoglycemia (often profound <60 mg/dl)
- Hyperammonemia
- Elevated aminotransferases (usually <500 U/ml)
- Thrombocytopenia
- Leukocytosis (white blood cell count >15,000)
- Hyperbilirubinemia (usually <10 mg/dl)
- Low albumin
- Hypofibrinogenemia (<300 mg/dl)
- Disseminated intravascular coagulation (DIC) (in 75%)

IMAGING STUDIES

- Ultrasound: Best used to rule out other diseases in the differential diagnosis such as gallbladder disease
- CT scan: Plays minimal role because of a high false-negative rate

TREATMENT

NONPHARMACOLOGIC THERAPY

- Patient is admitted to intensive care unit for stabilization.
- Fetus is delivered; spontaneous resolution usually follows delivery.
- Mode of delivery is based on obstetric indications and clinical assessment of disease severity.

ACUTE GENERAL Rx

- Decrease in endogenous ammonia through dietary protein restriction; neomycin 6 to 12 g/day PO to decrease presence of ammonia-producing bacteria; magnesium citrate 30 to 50 ml PO or enema to evacuate nitrogenous wastes from colon.
- Administration of IV fluids with glucose to keep glucose levels >60 mg/dl.
- Coagulopathy corrected with fresh frozen plasma.
- Avoidance of drugs metabolized by liver.
- Aggressive avoidance and treatment for nosocomial infections; consideration of prophylactic antibiotics.
- Monitor closely for development of complications such as hepatic encephalopathy, pulmonary edema, DIC, and respiratory arrest.
- Plasma exchange after delivery may result in a lower maternal mortality.

CHRONIC Rx

Orthotopic liver transplantation is the only treatment for irreversible liver failure.

DISPOSITION

- Before 1980, both maternal and fetal mortality rates were approximately 85%.
- Since 2008, maternal mortality rates have been less than 10%.
- Usually rapid return of liver function to normal after delivery.
- Minimal risk of recurrence with future pregnancies.

REFERRAL

- To tertiary health care facility as soon as diagnosis is suspected.
- Twenty percent of infants born to mothers with AFLP have LCHAD; after birth, all infants should be evaluated for the deficiency.

BASIC INFORMATION

DEFINITION

Febrile seizures are seizures that occur in febrile children (fever of at least 100.4° F [38° C]) between the ages of 6 and 60 mo in the absence of infection of the central nervous system (CNS), metabolic disturbance, or history of neonatal seizures or a previous unprovoked seizure. Febrile seizures are subdivided into two categories: Simple and complex. Simple febrile seizures last <15 min, are generalized (without a focal component), and occur once in a 24-hr period, whereas complex febrile seizures are prolonged (>15 min), show focal neurologic signs, or occur more than once in 24 hr.

SYNONYMS

Febrile convulsions
Seizures, febrile

ICD-10CM CODE
R56.0 Febrile convulsions

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Febrile seizures are the most common seizures of childhood. 2% to 5% of children will have a febrile seizure by age 60 mo. Simple febrile seizures represent 65% to 90% of febrile seizures.
PREVALENCE: Represents up to 18% of all pediatric epilepsy syndromes
PREDOMINANT SEX AND AGE: Slightly more common in boys than girls
PEAK INCIDENCE: 6 to 60 mo

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Children with febrile seizures have normal physical and neurologic examinations.
- Viral illnesses are the predominant cause of febrile seizures.

ETIOLOGY

- Viral infections are a common cause of a fever that triggers febrile seizures.
- Febrile seizures tend to occur in families. Although clear evidence exists for a genetic basis of febrile seizures, the mode of inheritance is unknown.
- Febrile seizures are likely multifactorial with genetic and environmental factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- CNS infection (i.e., meningitis)
- Epilepsy

WORKUP

- It is important to first investigate whether an underlying infection exists. Fig. 1 describes guidelines for febrile seizure evaluation.
- In patients with simple self-limited febrile seizures with rapid return to consciousness and a normal neurologic examination, further workup is not routinely recommended.
- In patients with complex febrile seizures, laboratory workup and brain imaging are recommended.
- Electroencephalogram (EEG) is not routinely recommended in the evaluation of a neurologically healthy child with simple febrile seizures.

LABORATORY TESTS

- Routine blood workup (CBC with differential, complete metabolic panel (CMP), electrolytes), blood and urine cultures are often performed, but there is no evidence that these tests are necessary for identifying the cause of a simple febrile seizure.
- Cerebrospinal fluid (CSF) analysis: Follow lumbar puncture guidelines of the American Academy of Pediatrics.
- Lumbar puncture should be performed in children with febrile seizures and signs and symptoms of meningitis (e.g., neck stiffness, Kernig sign, Brudzinski sign), or if the patient history or examination suggests the presence of meningitis or other intracranial infection.
- In infants 6 to 12 mo of age with febrile seizures, lumbar puncture is an option if they have not received the recommended *Haemophilus influenza* type b (Hib) or pneumococcal vaccinations, or if their immunization status is unknown.
- Lumbar puncture is also considered an option in children with febrile seizures pretreated with antibiotics.

IMAGING STUDIES

- MRI of the brain is not required in the routine evaluation of patients with simple febrile seizures.
- Imaging of the brain should be considered in children with complex febrile seizures and in children with focal neurologic deficits.
- CT scans of the head should be avoided in children, if possible, due to exposure to radiation and the relative low yield of the test compared with MRI. CT scans of the head are reserved for neurologic emergencies and are adjusted for weight in children.

TREATMENT

Febrile seizures do not usually require antiepileptic drug treatment.

NONPHARMACOLOGIC THERAPY

Not applicable

GENERAL Rx

Symptomatic treatment of fever

CHRONIC Rx

No chronic treatment for febrile seizures is recommended.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Not applicable

DISPOSITION

- Treatment is not recommended.
- Febrile seizures should stop by age 60 mo.
- Risk of recurrence in the first 2 yr after an initial febrile seizure is 15% to 70%.

REFERRAL

Patients with recurrent febrile seizures need to be referred for a consultation by a pediatric neurologist.

PEARLS & CONSIDERATIONS

COMMENTS

- It is crucial to find out the etiology of the fever and to treat it appropriately.
- Patient with seizures and fever after age 60 mo are not classified as febrile seizures.

PREVENTION

Antipyretics do not reduce the recurrence risk of febrile seizures. However, fever should be treated and worked up independently of the diagnosis of febrile seizures.

PATIENT & FAMILY EDUCATION

- Children with febrile seizures do not need antiepileptic drug treatment.
- Patient education and information can be obtained at the Epilepsy Foundation: www.epilepsyfoundation.org. Parents should be reassured that children without underlying developmental problems will usually not have lasting neurologic effects from febrile seizures.

Felty Syndrome

BASIC INFORMATION

DEFINITION

Felty syndrome (FS) is originally defined as the triad of seropositive rheumatoid arthritis (RA), splenomegaly, and neutropenia. The hallmark of FS is a persistent, idiopathic neutropenia. Splenomegaly is extremely variable in its extent and is no longer an absolute diagnostic requirement; it is an extraarticular manifestation of seropositive RA.

SYNONYM

FS

ICD-10CM CODES

M05.00	Felty syndrome, unspecified site
M05.011	Felty syndrome, right shoulder
M05.012	Felty syndrome, left shoulder
M05.019	Felty syndrome, unspecified shoulder
M05.021	Felty syndrome, right elbow
M05.022	Felty syndrome, left elbow
M05.029	Felty syndrome, unspecified elbow
M05.031	Felty syndrome, right wrist
M05.032	Felty syndrome, left wrist
M05.039	Felty syndrome, unspecified wrist
M05.041	Felty syndrome, right hand
M05.042	Felty syndrome, left hand
M05.049	Felty syndrome, unspecified hand
M05.051	Felty syndrome, right hip
M05.052	Felty syndrome, left hip
M05.059	Felty syndrome, unspecified hip
M05.061	Felty syndrome, right knee
M05.062	Felty syndrome, left knee
M05.069	Felty syndrome, unspecified knee
M05.071	Felty syndrome, right ankle and foot
M05.072	Felty syndrome, left ankle and foot
M05.079	Felty syndrome, unspecified ankle and foot
M05.09	Felty syndrome, multiple sites

EPIDEMIOLOGY & DEMOGRAPHICS

- The lifetime risk of FS for a patient initially diagnosed with RA is estimated to be 1%. The prevalence has been steadily declining over the past two decades.
- Demographics are similar to RA, affecting 60% to 80% women.
- FS patients tend to have a family history of RA and be HLA-DR4 positive.
- Recognized in patients in their late 40s or early 50s who have had RA for >10 yr.
- FS is rare in African Americans because of the infrequency of HLA-DR4 in this population.

CLINICAL PRESENTATION

- Felty syndrome (FS) is an uncommon extraarticular manifestation of rheumatoid arthritis (RA) with neutropenia (absolute neutrophil counts <2000/μl) and splenomegaly.
  1. RA is typically severe, long-standing (at least >10 yr) with seropositive rheumatoid factor (RF) or anti-citrullinated peptide antibodies (ACPA).
- Extraarticular manifestations (rheumatoid nodules, vasculitis, skin lesions, pleuropericarditis, and other) are more frequently found in patients with FS than RA.
- One third of patients may have relatively inactive synovitis. Erythrocyte sedimentation rate (ESR) is almost always significantly elevated even in patients with inactive synovitis.
- Splenomegaly and neutropenia are rarely present before the arthritis.
- Mild hepatomegaly is common (up to 68%).
- The degree of splenomegaly varies and may be detectable only by imaging studies; the degree of splenomegaly has no correlation with the degree of neutropenia.
- Patients with FS have a twentyfold increased frequency of bacterial infections compared with other RA patients.
- FS patients have greater risk of developing non-Hodgkin lymphoma than RA patients. Similarly, FA patients are at increased risk of lung disease. Differentiation between large granular lymphocyte (LGL) leukemia and FS is necessary because both can present with neutropenia and are associated with RA.

ETIOLOGY

The pathogenesis of FS is probably multifactorial, including immune dysfunction resulting from an imbalance between granulocyte production and destruction from the circulatory pool.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Systemic lupus erythematosus
- LGL leukemia
- Drug reaction (conventional disease-modifying anti-rheumatic drugs [DMARDs] or biologic DMARDs)
- Myeloproliferative disorders
- Lymphoma or reticuloendothelial malignancies
- Cirrhosis with portal hypertension
- Sarcoidosis
- Tuberculosis
- Amyloidosis
- HIV infection
- Epstein-Barr virus infection
- Malaria

LABORATORY TESTS

- There is no single diagnostic test for patients with FS.
- CBC with differential to detect neutropenia <2000/μl, mild to moderate anemia, and mild to moderate thrombocytopenia.
- Elevated ESR, C-reactive protein.
- Elevated rheumatoid factor and/or anticyclic citrullinated peptide (anti-CCP) antibody titers, positive in 94% and 77%, respectively, with typically higher titers.
- Autoantibody levels are more frequently elevated in FS.
  1. Antinuclear antibody (ANA) positive in 67%
  2. Antihistone antibody positive in 83%
  3. Antineutrophil cytoplasmic antibody (ANCA) positive in 77%
  4. Anti-glucose-6-phosphate isomerase antibody positive in 92%
- HLA-DR4: positive in 98%.
- Immunoglobulin levels may be higher and complement levels lower in FS patients than in RA patients.
- Peripheral smear morphology and immunophenotypic analysis is essential to exclude LGL leukemia.
- Bone marrow examination, which typically shows myeloid hyperplasia with maturation arrest, is often necessary to exclude other causes of neutropenia.

IMAGING STUDIES

Ultrasonography or CT scan may be useful in diagnosing splenomegaly but is not necessary.

TREATMENT

ACUTE GENERAL Rx

The principal treatment interventions include nonpharmacologic measures to reduce the risk for infection and medications to control RA disease and alleviate the granulocytopenia.

- Splenectomy:
  1. Usually reserved for patients with profound neutropenia (<1000/mm^3) and severe recurrent infections despite treatment with synthetic disease-modifying antirheumatic drugs (cs-DMARDs) and/or biologic disease-modifying antirheumatic drugs (bDMARDs).
  2. Acutely reverses hematologic abnormalities.
  3. 25% to 30% have recurrent neutropenia, but the granulocyte count usually remains above the pre-splenectomy level.
  4. Improvement in frequency of recurrent infection is variable and not correlated with degree of hematologic improvement.
- DMARDs (conventional synthetic [csDMARDs] and biologic [bDMARDs]):
  1. Methotrexate (MTX) and rituximab (RTX) are the DMARDs that are preferred in patients with FS, as their benefits have been described in case reports and case series. Leflunomide may be used as an alternative to MTX in patients unable to take MTX. Abatacept is recommended for patients with inadequate response to MTX and RTX, and who require prednisone at dosages greater than 10 to 15 mg daily for control of arthritis and granulocytopenia.
  2. Tumor necrosis factor (TNF) inhibitors are avoided because they have been found to be an ineffective treatment for FS. Tocilizumab and tofacitinib have not been studied, but are avoided because each may cause neutropenia.
  3. Penicillamine, sulfasalazine, hydroxychloroquine, gold salt: Limited experience; infrequently used; not the first choice for FS.
- Corticosteroids:
  1. Overwhelming infection is the main barrier to the use of corticosteroids.

2. Prednisone 30 mg/day or more can elevate the neutrophil count, but this effect is often not sustained when the dose is reduced.
3. Pulse dosing is a potential alternative for short-term elevation of neutrophils.

- Granulocyte colony-stimulating factor/granulocyte-macrophage colony-stimulating factor:
  1. Improves neutrophil count but not arthritis and anemia of FS
  2. May be useful as adjunctive therapy during serious infection or in preparation for surgery

DISPOSITION

- Poor prognosis with recurrent infections because of neutropenia. The average mortality rate after diagnosis is 25% in 5 yr.
- Articular involvement can be severe in FS.

REFERRAL

- To a hematologist for treatment of neutropenia
- To a rheumatologist for treatment of RA

PEARLS & CONSIDERATIONS

COMMENTS

- Recurrent infections are the major cause of death.
- Neutropenia of FS can be effectively treated with DMARDs, the greatest experience with MTX.

Fertility Preservation in Women

BASIC INFORMATION

DEFINITION

Fertility preservation is the process of preserving eggs, sperm, or reproductive tissue for future use.

Patients typically seek fertility preservation techniques before undergoing sterilizing therapies for cancer treatment or for elective delay of childbearing.

SYNONYMS

Oncofertility
In vitro fertilization
Cryopreservation

ICD-10CM CODES

Z31.84	Encounter for fertility preservation procedure
Z31.62	Encounter for fertility preservation counseling (before cancer therapy) (before removal of gonads)
Z31.41	Encounter for fertility testing
Z31.9	Other special procreative management

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Given the emergence and novelty of fertility preservation techniques, the epidemiology has not been well established. Currently, little is known regarding the perceptions and prevalence of elective fertility preservation. However, there is a growing need for discussions regarding fertility options among cancer patients. In 2006, the American Society of Clinical Oncology published guidelines for oncologists to discuss the possibility of infertility and offer referral for fertility preservation consultation and treatment.

In 2017, nearly 12% of men and women found to have cancer were younger than 45 yr Furthermore, the prevalence of nonsurgical premature menopause in female cancer survivors was 9.1% by age 40, nearly tenfold higher than baseline. Recent literature shows that, among adolescent females with malignancies, 81% of them and 93% of parents were interested in fertility preservation, even if options were described as experimental.

PREDOMINANT SEX AND AGE: Fertility declines with age in both men and women, but the effects of age are more pronounced in women, particularly after age 35.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- An increasing proportion of women are choosing to delay childbearing to pursue educational degrees or for professional achievement.
- For women seeking to delayed childbearing, a thorough history and physical should be performed. A thorough reproductive history including previous pregnancies, spontaneous/elective abortions, and pregnancy complications; a gynecologic history including cysts, fibroids, sexually transmitted diseases, and endometriosis also needs to be included.
- A complete assessment of past medical diagnoses, illicit drug use, and family history is indicated. Specifically, age is a determining factor guiding management. The older a woman is at the time of oocyte cryopreservation, the lower the probability of live birth in the future. The highest probability of live birth after oocyte cryopreservation occurs for women ≤35 yr of age, whereas the maximum age for attempting oocyte cryopreservation may be as high as 45 yr.
- For patients undergoing sterilizing therapies, chemotherapy, or radiation, physicians should discuss the risk of treatment-induced infertility and possible interventions to preserve fertility. Ultimately, the optimal preservation approach depends on the type of gonadotoxic treatment (radiation vs. chemotherapy), time available, patient age, cancer type, partner status, costs, and storage.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Elective delay
- Gonadotoxic treatment with radiation
- Gonadotoxic treatment with chemotherapy

WORKUP

Initial workup requires a discussion of patient goals, ideal family size, and timeline. Physicians should set realistic expectations for their patients' most likely outcome. Factors such as age and number of retrieved oocytes can predict the probability of achieving a live birth. Online calculators are available to guide clinical management.

LABORATORY TESTS

Assessment of markers of ovarian reserve:

- Anti-Müllerian hormone concentration (>2.7 ng/ml is associated with improved oocyte quality)
- Day 3 follicle-stimulating hormone (<10 to 15 mIU/ml is normal)
- Day 3 estradiol concentration (<80 pg/ml is normal)
- Inhibin B (>45 pg/ml is normal)

IMAGING STUDIES

Consider an ultrasound-guided assessment of ovarian reserve:

- Antral follicle count (>3 to 4 is normal)
- Ovarian volume (>3 cc is normal)

TREATMENT

There exist a multitude of methods for fertility preservation:

- Cryopreservation:
  1. Embryo: This method is an established technique for fertility preservation; the percentage of live birth after embryo transfer is similar to the natural fecundity rate of 20% to 30%. Women undergo ovarian stimulation with gonadotropins followed by office oocyte retrieval via needle aspiration under ultrasound guidance. Oocytes are fertilized in vitro with partner or donor sperm. The subsequent embryos that arise are cryopreserved using either slow freezing or vitrification, and stored for future use; there is no time limit for embryo storage. Cryopreserved embryos are not associated with poor obstetrical outcomes. However, for women undergoing chemotherapy, certain time constraints make oocyte retrieve unfeasible. Additionally, ovarian stimulation may not be possible with estrogen-sensitive tumors.
  2. Oocytes: Oocyte cryopreservation is technically more challenging than embryo preservation. Given the increased water content in oocytes, cryopreservation risks ice crystals, excessive osmotic pressure, and electrolyte toxicity. Although the success rates tend to be lower than embryo cryopreservation, harvesting oocytes are more appealing for women without partners at the time of fertility preservation. Patient should be counseled extensively on their risk of transfer success and live birth. Large retrospective cohorts have shown that approximately 5% of thawed oocytes will successfully implant and 4% will result in a live birth in women whose average age was 33.
  3. Ovarian tissue: This technique remains in its infancy and is currently experimental. The advantages of this technique include faster time, preservation of many oocytes, and no ovarian stimulation necessary. The ovarian tissue can remain either in the pelvis or other locations throughout the body. Retrieval is often invasive, typically with laparoscopy.
- Transposition via oophoropexy: This technique can be useful in patients with planned radiation. The ovary can be removed from the field of radiation and transposed elsewhere in the pelvis.
- Gonadotropin-releasing hormone (GnRH) agonists: This technique is useful in women undergoing chemotherapy. GnRH agonists suppress ovarian function and are speculated to prevent toxic damage to oocytes caused by chemotherapy. This technique remains in its infancy. The efficacy and success have not been established, and this is therefore not the first-line therapy for fertility preservation.

Ultimately, a complete evaluation of patient goals, time available, and cancer type is necessary before selecting a method of fertility preservation.

DISPOSITION

Fertility preservation via cryopreservation of embryos or oocytes is completed in an outpatient setting. GnRH agonist therapy is also managed in an outpatient setting. Harvesting ovarian tissue and transposing via oophoropexy are more invasive procedures, requiring surgical management.

REFERRAL

The American Society of Clinical Oncology and the American Society of Reproductive Medicine recommend early referral to a reproductive endocrine and infertility specialist if fertility is a concern before treatment.

PEARLS & CONSIDERATIONS

COMMENTS

- Two major indications for fertility preservation include prior cancer treatment and elective delay of childbearing.
- Early referral to a reproductive endocrinology and infertility specialist is essential.
- A discussion of patient-centered reproductive goals should be initiated.
- Fertility preservation techniques should be reviewed, and the best option selected for each patient, specific to the situation and reproductive goals.

Fetal Alcohol Spectrum Disorder

BASIC INFORMATION

DEFINITION

- Adverse effects of alcohol on developing humans represent spectrum of structural anomalies and behavioral and neurocognitive disabilities, most accurately termed fetal alcohol spectrum disorder (FASD) (Table E1).
- Children at severe end of spectrum defined as having fetal alcohol syndrome (FAS).

SYNONYMS

Fetal alcohol spectrum disorder
FAS
FASD

ICD-10CM CODES

Q86.0	Fetal alcohol syndrome (dysmorphic)
P04.3	Newborn (suspected to be) affected by maternal use of alcohol

EPIDEMIOLOGY & DEMOGRAPHICS

- Alcohol considered to be most common teratogen to which the fetus is liable to be exposed. The percentage of pregnant women who consume alcohol has increased from 7.6% in 2012 to 10.2% in 2015.
- 10% report drinking alcohol during pregnancy and 2% to 4% admit to binge drinking. Binge drinking is associated with the development of behavioral problems and physical deformities.
- Most common cause of inheritable intellectual disability in the U.S.
- Prevalence is 1 to 2/1000 live births across the U.S. It is least prevalent in Hispanic children and most prevalent in Native American and Alaskan Natives.
- Each yr 40,000 babies are born with FASD.

RISK FACTORS

- Advanced maternal age (>30 yr)
- High parity
- African American, Alaskan Native, or Native Indian descent
- Binge drinking (>4 drinks per occasion)
- History of prior affected child
- Genetic susceptibility
- Undernutrition
- Low socioeconomic group

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Typical features:

- Growth retardation
  1. Prenatal or postnatal
  2. Height and/or weight <10%
- Facial dysmorphia (Fig. E1)
  1. Smooth philtrum
  2. Thin vermilion border
  3. Small palpebral fissure (<10%)
  4. Others: Epicanthic folds, ptosis of eyelids, flat nasal bridge and midface, upturned nose, railroad track ears, and so forth
- CNS abnormalities
  1. Structural
     a. Head circumference, 10%
     b. Clinically significant brain abnormalities observable through imaging
  2. Neurologic
     a. Neurologic problems not due to a postnatal insult or fever
  3. Functional
     a. Intellectual deficit
     b. Cognitive or developmental deficits
     c. Executive function deficits
     d. Motor function delays
     e. Problem with attention and hyperactivity
     f. Social skills
     g. Other problems such as sensory, pragmatic language, and memory

Rare birth defects:

- Cardiac
  1. Ventricular septal defect (VSD)
  2. Atrial septal defect (ASD)
  3. Tetralogy of Fallot
  4. Aberrant great vessels
- Skeletal
  1. Radioulnar synostosis
  2. Hypoplastic nails
  3. Clinodactyly (curved fifth finger)
  4. Shortened fifth digit
  5. Pectus excavatum and carinatum
  6. Klippel-Feil syndrome
  7. Hemivertebrae
  8. Camptodactyly
  9. Scoliosis
- Renal
  1. Aplastic kidneys
  2. Dysplastic kidneys
  3. Ureteral duplication
  4. Hypoplastic kidneys
  5. Hydronephrosis
  6. Horseshoe kidneys
- Ocular
  1. Strabismus
  2. Refractive problems
  3. Retinal vascular abnormalities
- Auditory
  1. Conductive hearing loss
  2. Neurosensory hearing loss
- Others
  1. Hockey stick–like palmar crease

ETIOLOGY

- Prenatal damage comes about primarily by direct action of ethanol or its metabolites (e.g., acetaldehyde) on the fetus.
- Exact damaging mechanism is unclear.
- Although the damaging effect of alcohol is different in the various phases of pregnancy, it is by no means limited to first trimester.
- No exact dose-response relationship between alcohol consumed during prenatal period and extent of damage inflicted on infant.
- An occasional drink during pregnancy carries no risk to the fetus, but no level of drinking is known to be safe during pregnancy.
- The least significant effect recognized at 2 drinks/day is smaller birth weight (160 g less than average).
- Until 4 to 6 drinks/day are consumed, no additional subtle clinical features are evident.
- Most children who have FAS have been born to frankly alcoholic mothers whose intake is ≥8 to 10 drinks/day, and those who engage in binge drinking.
- The risk of serious problem in the offspring of a chronically alcoholic woman is ~30% to 50%; the greatest risk is mental retardation.

SECONDARY DISABILITIES

- Mental health problems
- Dependent living
- Employment problems
- Disruptive school problems
- Trouble with law
- Confinement
- Inappropriate sexual behavior
- Alcohol or drug problems

TABLE E1 Institute of Medicine's Diagnostic Criteria for Fetal Alcohol–Related Abnormalities

Category 1	
FAS with confirmed maternal alcohol exposure	Presence of classic triad of growth retardation, characteristic facial dysmorphology, and neurodevelopmental abnormalities. This is often defined as full-blown FAS
Category 2	
FAS without confirmed maternal alcohol exposure	Triad in category 1 is present without confirmed maternal drinking
Category 3	
Partial FAS with confirmed maternal alcohol exposure	Presence of some of the characteristic facial anomalies plus growth retardation or CNS neurodevelopmental abnormalities or behavioral/cognitive abnormalities
Category 4	
FAS with confirmed maternal alcohol exposure and alcohol-related birth defects	Some congenital anomalies as a result of alcohol toxicity
Category 5	
FAS with confirmed maternal alcohol exposure and alcohol-related neurodevelopmental disorder	Evidence of CNS neurodevelopmental abnormalities, a complex pattern of behavioral/cognitive abnormalities, or both, but not necessarily any obvious physical changes

CNS, Central nervous system; *FAS,* fetal alcohol syndrome.

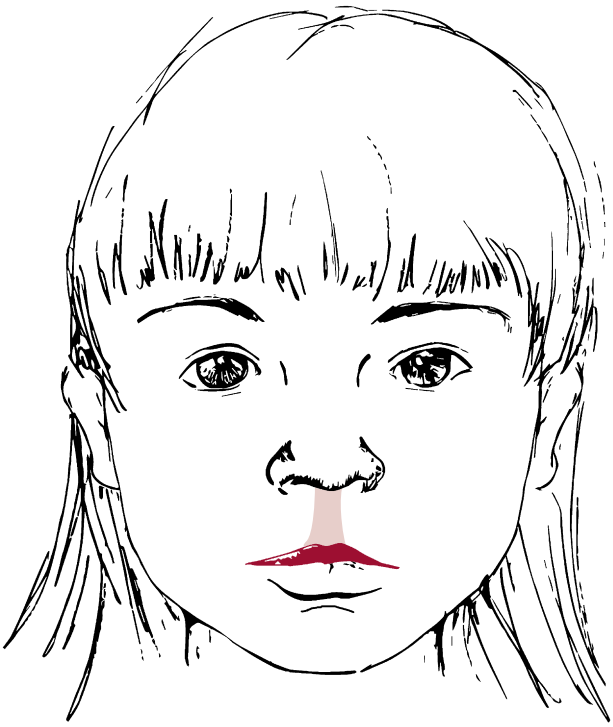

FIG. E1 The three most prominent and consistent facial abnormalities of fetal alcohol syndrome occur in the midface and give this 6-yr-old girl the distinctive appearance: short palpebral fissures that hide the medial and lateral portions of her eyes, smooth philtrum (the normally indented vertical groove between the bottom of the nose and the upper lip), and a thin upper lip. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

Dx DIAGNOSIS

- It is a diagnosis of exclusion.
- Diagnosis is difficult prenatally and at birth. Most cases are not diagnosed until school age.
- As the characteristic facial features tend to become decreasingly recognizable as the child reaches adolescence, the diagnosis becomes increasingly difficult with advancing age.
- Prenatal exposure to alcohol is not sufficient to warrant a diagnosis. According to the CDC, diagnosis of FAS requires three specific findings and history of prenatal alcohol exposure:
  1. Growth restriction (intrauterine or postnatal)
  2. CNS involvement
  3. Documentation of all three facial abnormalities (smooth philtrum, thin vermilion border, and short palpebral fissure)
- Imaging recommendation during pregnancy with alcohol exposure:
  1. High-risk anatomy scan
  2. Serial growth scan
  3. Fetal echocardiogram at 22 to 24 weeks' intrauterine pregnancy
- Measurement of the ethyl esters of fatty acids in the meconium and hair of the newborn can substantiate maternal alcohol exposure.
- In school-aged children, the diagnostic process should include a thorough psychological evaluation that assesses multiple domains. Also, supplement the observation by obtaining standardized testing through early intervention programs, public schools, and psychologists in private practice.

DIFFERENTIAL DIAGNOSIS

- Other causes of symmetric growth retardation including intrauterine infection and aneuploidy.
- Aneuploidy (T21, T18, T13).
- Syndromes with overlapping features of FAS:
  1. Fetal anticonvulsant syndrome
  2. Maternal phenylketonuria
  3. Toluene embryopathy
  4. Velocardiofacial syndrome (deletion 22q11)
  5. Williams syndrome
  6. Dubowitz syndrome
  7. Cornelia de Lange syndrome

Rx TREATMENT

- As there is no cure for FAS, we need to emphasize prevention.
- For women who are planning pregnancy or who could become pregnant, the United States Surgeon General recommends the safest course: to avoid alcohol entirely during pregnancy.
- Women of childbearing age who are not pregnant should drink ≤7 alcoholic drinks/wk and ≤3 drinks on any one occasion.
- Preconception counseling should be offered to women of childbearing age who are at risk for an alcohol-exposed pregnancy.

TABLE E2 T-ACE Questions*

T (tolerance)	How many drinks does it take to make you feel high? (3 or more drinks = 2 points)
A (annoyed)	Have people annoyed you by criticizing your drinking? (Yes = 1 point)
C (cut down)	Have you felt you ought to cut down on your drinking? (Yes = 1 point)
E (eye opener)	Have you ever had to drink first thing in the morning to steady your nerves or to get rid of a hangover? (Yes = 1 point)

*A score of 2 or more indicates heavy or problem drinker. Its sensitivity is 70% and specificity is 85%.

TABLE E3 TWEAK*

T (tolerance)	How many drinks does it take before you begin to feel the first effects of alcohol? (3 or more drinks = 2 points)
W (worried)	Have close friends or relatives worried about your drinking in the past year? (Yes = 2 points)
E (eye opener)	Do you sometimes take a drink in the morning when you first get up? (Yes = 1 point)
A (amnesia)	Has a friend or family member ever told you about things you said or did while you were drinking that you could not remember? (Yes = 1 point)
K (kut down)	Do you sometimes feel the need to cut down on your drinking? (Yes = 1 point)

*A total of 3 or more points indicates that the woman is likely to be a heavy or problem drinker. Its sensitivity is 79% and specificity is 83%.

- Screen all pregnant women for alcohol use.
- The National Institute on Alcohol Abuse and Alcoholism recommends that any woman who reports drinking >7 drinks/wk or >3 drinks on a given day be further assessed for alcohol-related problems.
- The T-ACE (Table E2) and TWEAK (Table E3) questionnaires are used to identify women drinking enough to potentially damage the fetus. The CAGE questionnaire is less sensitive for screening pregnant women.
- Effective treatment alternatives for women who screen positive for hazardous alcohol use include brief interventions to promote reductions in alcohol use and that facilitate referral to specialized treatment programs.
- Discontinuation or reduction of alcohol consumption at any point in pregnancy may be beneficial.

- The use of alcohol-containing tonics and medications should be avoided. This applies to medications with an alcohol base when the concentration exceeds 10%.
- Alcoholism is one of the few situations in which pregnancy interruption may be discussed with the patient as it may result in FAS.
- Early diagnosis and appropriate treatment may decrease secondary disabilities and recurrence in future pregnancies.
- A child should be referred for full FAS evaluation when substantial prenatal alcohol use by the mother has been confirmed (>7 drinks/wk, >3 drinks on multiple occasions, or both).
- If substantial prenatal exposure is known, with no other positive criteria, the physician should document exposure and closely monitor the child's growth and development.
- When information about prenatal exposure is unknown, a child should be referred for full FAS if any of the following conditions are present: (1) all three dysmorphic facial features (smooth philtrum, thin vermilion border, and small palpebral fissure), (2) one or more of these facial features with growth deficit, (3) one or more facial features with one or more CNS abnormalities, (4) one or more dysmorphic facial features with growth deficit and one or more CNS abnormalities, or (5) any report of concern by a caregiver or parent that a child has or may have FAS.
- Infants and children who are diagnosed with FAS should be evaluated by a physician who is knowledgeable and competent in the evaluation of neurodevelopment and psychosocial problems associated with the diagnosis.
- A multidisciplinary team including a clinical geneticist, developmental pediatrician, mental health professional, social worker, and education specialist is often necessary for management.
- Treatment options include:
  1. Medications to help with symptoms
  2. Behavior and education therapy
     a. Friendship training
     b. Specialized math training
     c. Executive function training
     d. Parent-child interaction training
     e. Parenting and behavior management training
  3. Parenting training
     a. Concentrate on child's strengths and talents.
     b. Accept child's limitations.
     c. Be consistent with everything.
     d. Use concrete language and examples.
     e. Use stable routine that does not change daily.
     f. Keep everything simple.
     g. Be specific (i.e., say exactly what you mean).
     h. Structure your child's world to provide a foundation for daily living.
     i. Use visualized aids, music, and hands-on activities to help your child learn.
     j. Use positive reinforcement often.
     k. Supervise.
     l. Repeat, repeat, and repeat.
  4. Emphasis on the following protective factors helps reduce the effects and also assists people with this condition to reach their full potential:
     a. Diagnosing before 6 yr
     b. Living in stable nurturing home environment in school yrs
     c. Absence of violence
     d. Involvement in special education and social services
  5. Alternative approaches such as biofeedback, auditory training, relaxation therapy, visual imagery, yoga/exercise, acupuncture/acupressure, massage, Reiki, energy healing, animal-assisted therapy, and so forth may play a role.

BASIC INFORMATION

DEFINITION

A traveler who returns from a foreign country with a fever or develops a fever within a month of returning.

ICD10-CM CODES

A50	Fever of other and unknown origin
A95	Yellow fever
A90	Dengue fever
A01	Typhoid and paratyphoid fever
B54	Malaria, malarial (fever)
A98.8	Other specified viral hemorrhagic fever

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Fever was the chief complaint in 28% of travelers who reported to a travel clinic. Mortality is between 0.2% and 0.5%. According to the CDC, the specific cause of fever may not be diagnosed in up to 25% or more of returned travelers.

PEAK INCIDENCE: Location and timing of travel influences the incidence of fever.

RISK FACTORS: Morbidity and mortality increased among elderly and young travelers.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- A detailed history on the trip must be obtained, including areas of travel, activities, sleeping arrangements, pre-trip immunizations, comorbidities, and use of malaria prophylaxis.
- If the incubation period is <21 days, the most common diseases include malaria, typhoid fever, and dengue. Also consider Japanese encephalitis, meningococcemia, plague, typhus, yellow fever, and viral hemorrhagic fevers.
- If incubation period is >21 days, the most common diseases include malaria, tuberculosis (TB), and hepatitis A. Consider acute HIV infection, acute systemic schistosomiasis, borreliosis, other viral hepatitis, and West African trypanosomiasis (Table 1).

If there is fever accompanied by any of the following syndromes, CDC recommends further investigation because of a high risk of a disease that affects public health and immediate infection control and containment/isolation procedures are indicated:

- Skin rash with or without conjunctivitis (e.g., measles, meningococcemia, hemorrhagic fevers such as Ebola)
- Rapid respiratory rate (e.g., influenza, Middle East respiratory syndrome [MERS], pneumonic plague)
- Persistent cough (e.g., tuberculosis, pertussis)
- Decreased consciousness (e.g., meningococcal meningitis, rabies)
- Bruising or unusual bleeding without previous injury (e.g., hemorrhagic fevers)
- Persistent voluminous diarrhea (e.g., cholera)
- Persistent vomiting other than air or motion sickness (e.g., norovirus infection)
- Jaundice (e.g., hepatitis A)
- Flaccid paralysis of recent onset (e.g., polio)

Common causes of fever in returning travelers:

- Malaria: Most common cause of fever after travel in endemic areas. Presents with abrupt rigors, relapsing high fevers, diaphoresis, malaise, headaches, myalgias, abdominal pain, nausea, vomiting, diarrhea.
- Enteric fevers (typhoid fever, paratyphoid fever): Clinical syndrome of sustained fever, anorexia, abdominal pain, malaise. Diarrhea usually precedes other symptoms. May see hepatosplenomegaly and rose spots on physical exam. Vaccines are 70% effective. Patient will have traveled to a developing nation. Diagnoses by identification of organism in blood, stool, or urine.
- Dengue fever ("breakbone fever"): Abrupt fever, severe myalgia, headaches with retroorbital pain, maculopapular blanching rash, petechial fever similar to meningococcus.

Hemorrhagic fevers:

- Yellow fever: Classic presentation of jaundice, black emesis, albuminuria. Patients may also have conjunctival injection, facial flushing, relative bradycardia.
- Ebola: Recent large outbreaks in West Africa with recurring smaller outbreaks. Symptoms of fever, myalgia, and abdominal pain that progress to hemorrhage, shock, and end organ failure.

Fever with central nervous system involvement:

- Consider malaria, meningococcal meningitis, tuberculosis, rabies.
- Japanese encephalitis: Asian distribution, associated with rural rice fields. High fevers, headache, nuchal rigidity, and seizures.

Chronic fevers: Relapsing or constant fever >3 wk:

- African trypanosomiasis (African sleeping sickness): Bite from the tsetse fly, painless chancre that grows for 2 to 3 wk. Fever unresponsive to antimalarials, malaise, wasting, behavioral and neurologic changes, encephalitis, coma occur.
- American trypanosomiasis (Chagas disease): Spread by reduviid bug (kissing or assassin bug). Painful edema at wound near mouth, unilateral periorbital edema, lymphadenopathy for 2 to 4 wk. Latent phase with nerve destruction causing cardiac and GI manifestations.
- Middle East respiratory syndrome (travel to or near the Arabian Peninsula): Fever, acute respiratory distress syndrome, or pneumonia.

ETIOLOGY

Table 2 summarizes the constellations of exposures and clinical presentations suggestive of particular diagnoses in returning travelers.

TABLE 1 Incubation Periods of Common Travel-Related Infections*

Short Incubation (<10 days)	Medium Incubation (10-21 days)	Long Incubation (>21 days)
Malaria	Malaria	Malaria
Arboviruses including dengue, yellow fever, Japanese encephalitis	Flaviviruses: Tick-borne encephalitis and Japanese encephalitis	Schistosomiasis
Hemorrhagic fevers: Lassa, ebola, South American arenaviruses	Hemorrhagic fevers: Lassa, ebola, Crimean-Congo	Tuberculosis
Respiratory viruses including severe acute respiratory syndrome	Acute HIV infection	Acute HIV infection
Typhoid and paratyphoid	Typhoid and paratyphoid	Viral hepatitis
Bacterial enteritis	*Giardia*	Filariasis
Rickettsia: Spotted fever group—Rocky Mountain spotted fever, African tick typhus, Mediterranean spotted fever, scrub typhus, Q fever	*Rickettsia*: Flea-borne, louse-borne, and scrub typhus, Q fever, spotted fevers (rare)	*Rickettsia:* Q fever
Bacterial pneumonia including *Legionella*	Cytomegalovirus	Secondary syphilis
Relapsing fever	*Toxoplasma*	Epstein-Barr virus including mononucleosis
Amebic dysentery	Amebic dysentery	Amebic liver disease
Meningococcemia	Histoplasmosis	Leishmaniasis
Brucella (rarely)	*Brucella*	*Brucella*
Leptospirosis	Leptospirosis	Bartonellosis (chronic)
Fascioliasis	Babesiosis	Babesiosis
Rabies (rarely)	Rabies	Rabies
African trypanosomiasis (acute), East African (rarely)	East African trypanosomiasis (acute)	West African trypanosomiasis (chronic)
	Hepatitis A (rarely)	Cytomegalovirus
	Measles	

*Diseases that commonly have variable incubation periods are shown more than once. However, most diseases may rarely have an atypical incubation period, and this is not shown here.
HIV, Human immunodeficiency virus.
From Bennet et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.

TABLE 2 Constellations of Exposures and Clinical Presentations Suggestive of Particular Diagnoses in Returned Travelers*

Exposure Scenario	Distinctive Findings	Diagnosis
Any exposure in any area with documented malaria transmission	Fever with or without any other finding	Malaria
Most tropical countries	Fever and altered mental status	Malaria, meningococcal meningitis, rabies, West Nile virus
Budget travel to India, Nepal, Pakistan, or Bangladesh	Insidious onset, high unremitting fever, toxic patient, paucity of physical findings	Enteric fever due to *Salmonella typhi* or *Salmonella paratyphi*
Freshwater recreational exposure in Africa	Fever, eosinophilia, hepatomegaly, negative malaria smear	Acute schistosomiasis (Katayama fever)
Bitten by *Aedes aegypti* in Central America, Southeast Asia, or the South Pacific	Fever, headache, myalgia, diffuse macular rash, mild to moderate thrombocytopenia	Dengue
Bitten by *A. aegypti* or *Aedes albopictus* in India, Malaysia, Singapore, the Caribbean, or an island in the Indian Ocean	Fever, headache, myalgia, diffuse macular rash, arthralgia, tenosynovitis often followed by chronic polyarthritis after the fever resolves	Chikungunya fever
Hunting or visiting game reserves in southern Africa	Fever, eschar, diffuse petechial rash	African tick typhus due to *Rickettsia africae*
Travel to Southeast Asia	Fever, eschar, diffuse petechial rash	Scrub typhus due to *Orientia tsutsugamushi*
Hiking, biking, swimming, rafting with exposure to fresh surface water	Fever, myalgia, conjunctival suffusion, mild to severe jaundice, variable rash	Leptospirosis
Cruise, elderly traveler	Influenza-like illness	Influenza A or B
Outdoor exposure anywhere in the Americas	Large, single furuncular lesion anywhere on body, with sense of movement inside	Myiasis due to *Dermatobia hominis* (botfly)
Clothing washed or dried out of doors in Africa	Multiple furuncular lesions around clothing contact points with skin	Myiasis due to *Cordylobia anthropophaga* (tumbu fly)
New sexual partner during travel	Fever, rash, mononucleosis-like illness	Acute human immunodeficiency virus infection
Travel to any developing country or to Western Europe	Coryza, conjunctivitis, Koplik spots, rash	Measles
Longer visit to humid areas of Africa, the Americas, or Southeast Asia	Asymptomatic eosinophilia or with periodic cough or wheezing	Strongyloidiasis
Sand fly bite in either New or Old World tropical area	Painless skin ulcer with clean, moist base in exposed area	Cutaneous leishmaniasis
Resort hotel in southern Europe, ± exposure to whirlpool spas	Pneumonia	Legionnaires' disease
Explored a cave in the Americas	Fever, cough, retrosternal chest pain, hilar adenopathy	Histoplasmosis
Ingestion of unpasteurized goat cheese	Chronic fever, fatigue	*Brucella melitensis*
Long trip to West/Central Africa	Afebrile, intensely pruritic, evanescent truncal maculopapular rash	Onchocerciasis
Long trip to West/Central Africa	Migratory localized angioedema or swellings over large joints, eosinophilia	Loiasis
Safari to game parks of East Africa	Fever, nongenital chancre, fine macular rash	East African trypanosomiasis
Travel to Australia	Fever, fatigue, polyarthritis	Ross River virus
Farming areas of India and Southeast Asia	Fever, altered mental status, paralysis	Japanese encephalitis
Forested areas of central and eastern Europe and across Russia	Fever, altered mental status, paralysis	Tick-borne encephalitis
Rodent exposure in West Africa	Fever, sore throat, jaundice, hemorrhagic manifestations	Lassa fever
Ingestion of sushi, ceviche, or raw freshwater fish	Migratory nodules in truncal areas with overlying erythema or mild hemorrhage	Gnathostomiasis
Returning Hajj pilgrim or family contact	Fever, meningitis	Meningococcal meningitis
Ingestion of snails, fish, or shellfish in Asia or Australia	Eosinophilic meningitis	Angiostrongyliasis, gnathostomiasis
Diabetic or compromised host with exposure to moist terrain in Asia or Australia	Fever, sepsis, pneumonia or multifocal abscesses	Melioidosis
Summertime exposure to rodent droppings in Scandinavia	Fever with decreased renal function	Puumala virus
Ingestion of undercooked meat of any animal in any country	Fever, facial edema, myositis, increased creatine phosphokinase, massive eosinophilia, normal erythrocyte sedimentation rate	Trichinosis
Unvaccinated, returning from sub-Saharan Africa or forested areas of Amazonia	Fever, jaundice, proteinuria, hemorrhage	Yellow fever
Exposure to farm animals	Pneumonia, mild hepatitis	Q fever
Possible tick exposure almost anywhere	Fever, headache, rash, conjunctival injection, hepatosplenomegaly	Tick-borne relapsing fever
Poor hygienic conditions with possible body louse exposure in Ethiopia or Sudan	Fever, headache, rash, conjunctival injection, hepatosplenomegaly	Louse-borne relapsing fever

*The table includes illnesses of travelers (listed first) as well as less common diseases with presentations that should suggest the possibility of the appropriate diagnosis. Many diseases have a spectrum of presentation, and the table describes the most common presentations of these diseases. Many diseases have a spectrum of geographic origins, and the table describes the most common exposures seen in daily practice.

From Bennet et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Table 3 is a table from CDC with clinical findings and infections to consider. Table 4 is also from the CDC, pairing regions with common tropical diseases that may be causing fever.

- Malaria
- Dengue
- Hemorrhagic fevers: Yellow fever, Ebola
- Enteric fever: Typhoid, paratyphoid
- Meningococcemia
- TB
- Acute HIV
- Trypanosomiasis
- Viral hepatitis
- Common nontravel causes of fever: Urinary tract infection, upper respiratory tract infections

WORKUP

Must consider travel location, activities, endemic diseases

LABORATORY TESTS

Consider:

- CBC
- Comprehensive metabolic panel
- Prothrombin time/international normalized ratio, partial thromboplastin time
- Urinalysis
- Blood, urine stool cultures
- Cerebrospinal fluid analysis, gram stain, culture
- Rapid HIV screen
- Serial blood smears q8 to 12h over 2 days
- Specific serology for suspected infections

IMAGING STUDIES

Not usually required, but consider as clinically indicated:

- Chest x-ray
- Upright abdominal x-ray
- CT: Head
- CT: Abdomen and pelvis

TABLE 3 CDC: Clinical Findings and Select Associated Infectious Diseases

Common Clinical Findings	Infections to Consider after Tropical Travel
Fever and rash	Dengue, chikungunya, Zika, measles, spotted fever or typhus group rickettsioses, enteric fever (skin lesions may be there or not), meningococcemia, acute HIV infection, varicella
Fever and abdominal pain	Enteric fever, amebic or pyogenic liver abscess
Fever and normal or low WBC count	Dengue, malaria, rickettsial infection, enteric fever, chikungunya Zika, acute HIV
Fever and hemorrhage	Viral hemorrhagic fevers (e.g., dengue, yellow, Ebola, Lassa fever), meningococcemia, leptospirosis, spotted fever group rickettsial infections)
Fever and arthralgia or myalgia (sometimes persistent)	Chikungunya, dengue, Zika, Ross River virus, muscular sarcocystosis, trichinellosis
Fever and eosinophilia	Acute schistosomiasis, drug hypersensitivity reaction, fascioliasis, sarcocystosis, trichinellosis, angiostrongyliasis, and other parasitic infections
Fever and respiratory symptoms / pulmonary infiltrates	Influenza and other common bacterial and viral pathogens, legionellosis, tuberculosis, acute schistosomiasis, Q fever, leptospirosis, Middle East respiratory syndrome, acute histoplasmosis, or coccidioidomycosis, psittacosis, melioidosis, pneumonic plague
Fever and altered mental status/ CNS involvement	Cerebral malaria, arboviral encephalitides (Jap. Encephalitis, West Nile virus), meningococcal meningitis, rabies, African trypanosomiasis, scrub typhus, angiostrongyliasis, tickborne encephalitis, rabies
Fever and jaundice	Acute viral hepatitis (A, B, C, E), yellow fever and other viral hemorrhagic fevers, severe malaria, leptospirosis
Mononucleosis syndrome	EBV, CMV, toxoplasmosis, acute HIV
Fever persisting >2 weeks	Malaria, enteric fever, EBV, CMV, toxoplasmosis, acute HIV, acute schistosomiasis, brucellosis, tuberculosis, Q fever, visceral leishmaniasis
Fever with onset >6 weeks after travel	Plasmodium vivax or ovale malaria, acute hepatitis (B, C, E), tuberculosis, amebic liver abscess, melioidosis, African trypanosomiasis

CMV, Cytomegalovirus; *CNS,* central nervous system; *EBV,* Epstein-Barr virus; *HIV,* human immunodeficiency virus; *WBC,* white blood cells.

TABLE 4 Regions with Common Tropical Disease

Geographic Area	Common Tropical Disease Causing Fever	Other Infections Causing Outbreaks or Clusters in Travelers
Caribbean	Chikungunya, dengue, malaria, Zika	Acute histoplasmosis, leptospirosis
Central America	Chikungunya, dengue, malaria (primarily Plasmodium vivax), Zika, enteric fever	Leptospirosis, histoplasmosis, coccidioidomycosis, leishmaniasis
South America	Chikungunya, dengue, malaria (primarily *P. vivax*), Zika	Bartonellosis, leptospirosis, enteric fever, histoplasmosis
South Central Asia	Dengue, enteric fever, malaria (primarily non-falciparum)	Chikungunya, scrub typhus
Southeast Asia	Dengue, malaria (primarily non-falciparum)	Chikungunya, leptospirosis
Sub-Saharan Africa	Malaria (primarily P. falciparum), tickborne rickettsiae, acute schistosomiasis, Dengue fever	African trypanosomiasis, chikungunya enteric fever, meningococcal meningitis

(CDC last update 6/2019)

Rx TREATMENT

Pretravel prevention should focus on proper vaccinations and prophylactic antimalarial antibiotics. Posttravel treatment depends on diagnosing or ruling out specific, known causes of fever in the returning traveler. Treatment ranges from supportive care to IV antibiotics, as with malaria and Dengue fever.

- Malaria (pediatric dosing, refer to CDC treatment table)
  Uncomplicated *Plasmodium falciparum* or species not identified:
  1. Artemether-lumefantrine (Coartem) 1 tab is 20 mg artemether/120 mg lumefantrine 3 day treatment schedule, 6 doses total
     Day 1: 1 dose and the second dose 8 hr later
     Day 2 and 3: 1 dose PO bid
     5 to <15 kg: 1 tab per dose
     15 to <25 kg: 2 tabs per dose
     25 to <35 kg: 3 tabs per dose
     35 kg and up: 4 tabs per dose
  2. Malarone (atovaquone/proguanil): 250 mg Atovaquone/100 mg Proguanil
     Malarone 4 tabs PO qd for 3 days
  3. Quinine sulfate 542 mg base (650 mg salt) PO q8h for 3 to 7 days *plus*
     Doxycycline 100 mg PO q12h for 7 days *or*
     Tetracycline: 250 mg PO QID for 7 days *or*
     Clindamycin: 20 mg base/kg/day PO divided tid for 7 days
  4. Mefloquine (not suggested unless the others cannot be taken because of high incidence of neuropsychiatric side effects, high resistance in Southeast Asia): 684 mg base (750 mg salt) PO initial dose, 456 mg base (500 mg salt) PO 6 to 12 hr after the first dose; total dose: 1250 mg salt
- Severe malaria:
  1. IV artesunate: Give 2.4 mg/kg per dose; administer 1 dose at 0, 12, 24, and 48 hr for a total of 4 doses
  Followed by 1 of the following:
     a. Coartem: treatment as above
     b. Doxycycline (clindamycin in pregnant patients): Treatment as above if patient can tolerate PO, otherwise give 100 mg IV q12h and then switch to oral doxycycline as soon as patient can take oral medication; for IV use, avoid rapid administration; treatment course = 7 days

Clindamycin: Treatment as above, unless patient cannot tolerate PO, 10 mg base/kg loading dose IV followed by 5 mg base/kg IV q8h; switch to PO clindamycin as soon as possible; avoid rapid administration for IV use; treatment course is 7 days

c. Mefloquine if there is no other option

- Dengue: Supportive care, fever and pain control, prevent dehydration
  1. NSAIDs and aspirin contraindicated due to increased bleeding risk
  2. Acetaminophen or paracetamol q6h
  3. Cool compresses, ice compresses, bath if necessary
- Typhoid fever: Fluoroquinolone (ciprofloxacin), third-generation cephalosporins (cefixime or ceftriaxone), azithromycin. Duration varies based on severity.
- Hemorrhagic viruses: Supportive care
- Meningococcus: Standard bacterial meningitis care

DISPOSITION

- Depending on the specific disease, severity of disease, and possibility of transmission.
- Patients may have outpatient or inpatient medical treatment.
- The most severe cases may need ICU and/or isolation.

REFERRAL

- Infectious disease consult
- Contact the CDC for recommendations pertaining to endemic diseases and treatment
- Some medical treatments and diagnostic testing must be sent from the CDC
- Mandatory reporting of some diseases to CDC

PEARLS & CONSIDERATIONS

COMMENTS

- The differential depends on the geography. Also consider travel to endemic areas, pretrip immunizations, comorbidities, non-travel-related diseases, sleeping arrangements, activities, and immunocompromised status.
- Until demonstrated otherwise, some travel medicine experts recommend assuming that all febrile travelers coming from malaria endemic regions have malaria.

PREVENTION

Check the CDC website and the Yellow Book for pretrip vaccinations.

Thwaites GE et al: Approach to fever in the returning traveler, *N Engl J Med* 376(6):548-560, 2017.

BASIC INFORMATION

DEFINITION

Fever of undetermined origin (FUO) was first defined by Petersdorf and Beeson in 1961 as an illness characterized by temperatures >38.3° C (101° F) on several occasions for >3 wk with an uncertain diagnosis after 1 wk of study in the hospital. With the increased availability of outpatient evaluation, the requirement of hospitalization for diagnosis was removed. As of 2017, the widely accepted definition of FUO is:

- Temperature ≥38.3° C (101° F) on at least two occasions
- Duration of illness ≥3 wk or multiple febrile episodes in ≥3 wk
- Not immunocompromised
  1. Neutropenic >1 wk in last 3 mo
  2. Known HIV
  3. Hypogammaglobulinemia
  4. 10 mg prednisone or equivalent for at least 2 wk

FUO can be classified into classic, nosocomial (health care associated), neutropenic (immune deficient), and HIV-associated. Table 1 provides a summary of definitions and major features of subtypes of FUO.

SYNONYMS

Fever of unknown origin
Pyrexia of unknown origin

ICD-10CM CODE
R50.9 Fever, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Due to advances in medical knowledge and technology, the distribution of causes of FUO has changed.
- Improved imaging and culture techniques have led to decreased diagnosis secondary to malignancy or infection.
- In recent yrs, more FUOs have no identified cause and eluded diagnosis:
  1. In prospective study of 73 immunocompetent patients with FUO, 51% had no identified cause.

CLINICAL PRESENTATION

Significant fever (≥38.3° C [101° F]) that has persisted for longer than an acute self-limiting illness would be expected to and without identified etiology despite reasonable investigations in whatever setting is appropriate.

ETIOLOGY

FUO can be divided into four categories:

- Infectious (17% to 35%)
  1. Localized:
     a. Abscess (intraabdominal, pelvic, renal, dental, intracranial)
     b. Endocarditis (including subacute and culture negative)
     c. Infected peripheral vessels
     d. Osteomyelitis
     e. Urinary tract infection
     f. Sinusitis
     g. *Clostridium difficile* colitis
  2. Generalized:
     a. Bacterial: Typhoid fever, bartonellosis, brucellosis, Q fever
     b. Viral: HIV, cytomegalovirus (CMV), Epstein-Barr virus (EBV), multicentric Castleman disease
     c. Fungal: Histoplasmosis, blastomycosis, cryptococcosis, coccidioidomycosis
     d. Mycobacterial: Tuberculosis (extrapulmonary, military)
     e. Parasitic: Malaria, toxoplasmosis, visceral leishmaniosis, amoebic abscess
- Noninfectious inflammatory (24% to 36%)
  1. Adult Still disease
  2. Giant cell arteritis, temporal arteritis, polymyalgia rheumatics
  3. Other vasculitides: Polyarteritis nodosa, Takayasu arteritis, granulomatosis with polyangiitis, mixed cryoglobulinemia
  4. Other rheumatologic disorders: Systemic lupus erythematous, rheumatoid arthritis
- Malignancy (10% to 20%)
  1. Lymphoma
  2. Leukemia
  3. Myelodysplastic syndrome
  4. Solid tumors: Renal cell carcinoma, hepatocellular carcinoma, metastatic disease

TABLE 1 Summary of Definitions and Major Features of the Four Subtypes of Fever of Undetermined Origin

Feature	Classic FUO	Health Care–Associated FUO	Immune-Deficient FUO	HIV-Related FUO
Definition	>38.0° C, (100.4° F) >3 wk, >2 visits or 1 wk in hospital	≥38.0° C (100.4° F), >1 wk, not present or incubating on admission	≥38.0° C (100.4° F), >1 wk, negative cultures after 48 hr	≥38.0° C (100.4° F), >3 wk for outpatients, >1 wk for inpatients, HIV infection confirmed
Patient location	Community, clinic, or hospital	Acute care hospital	Hospital or clinic	Community, clinic, or hospital
Leading causes	Cancer, infections, inflammatory conditions, undiagnosed, habitual hyperthermia	Health care–associated infections, postoperative complications, drug fever	Majority due to infections, but cause documented in only 40%-60%	HIV (primary infection), typical and atypical mycobacteria, CMV, lymphomas, toxoplasmosis, cryptococcosis, immune reconstitution inflammatory syndrome (IRIS)
History emphasis	Travel, contacts, animal and insect exposure, medications, immunizations, family history, cardiac valve disorder	Operations and procedures, devices, anatomic considerations, drug treatment	Stage of chemotherapy, drugs administered, underlying immunosuppressive disorder	Drugs, exposures, risk factors, travel, contacts, stage of HIV infection
Examination emphasis	Fundi, oropharynx, temporal artery, abdomen, lymph nodes, spleen, joints, skin, nails, genitalia, rectum or prostate, lower limb deep veins	Wounds, drains, devices, sinuses, urine	Skinfolds, IV sites, lungs, perianal area	Mouth, sinuses, skin, lymph nodes, eyes, lungs, perianal area
Investigation emphasis	Imaging, biopsies, sedimentation rate, skin tests	Imaging, bacterial cultures	CXR, bacterial cultures	Blood and lymphocyte count; serologic tests; CXR; stool examination; biopsies of lung, bone marrow, and liver for cultures and cytologic tests; brain imaging
Management	Observation, outpatient temperature chart, investigations, avoidance of empirical drug treatments	Depends on situation	Antimicrobial treatment protocols	Antiviral and antimicrobial protocols, vaccines, revision of treatment regimens, good nutrition
Time course of disease	Mos	Wks	Days	Wks to mos
Tempo of investigation	Wks	Days	Hours	Days to wks

CMV, Cytomegalovirus; *CXR,* chest radiograph; *FUO,* fever of undetermined origin; *HIV,* human immunodeficiency virus; *IV,* intravenous.
Adapted from Mandell GL et al (eds): *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 7, Philadelphia, 2010, Churchill Livingstone. Borrowed from Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.

- Miscellaneous (3% to 15%)
  1. Drug-induced fever
  2. Inflammatory bowel disease
  3. Sarcoidosis
  4. Pulmonary embolism/deep vein thrombosis
  5. Alcoholic hepatitis
  6. Familial Mediterranean fever
  7. Factitious fever
- No diagnosis in 16% to 39% of cases

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Over 200 possible diagnoses for FUO

WORKUP

- By definition, FUO is a diagnostic challenge. As the list of possible causes is extensive, there is no useful, clear-cut algorithmic approach.
- Accurate history and careful physical examination are essential. Table E2 describes an approach to the patient with FUO based on history and physical findings.
- Laboratory tests and imaging dependent on medical history clues and physical findings.
- When in doubt, perform another complete history and physical examination. Examples of subtle physical findings in patients with FUO are described in Table 3.

MEDICAL HISTORY CLUES

- Duration, accompanying symptoms (rigor, drenching sweats)
  1. Degree of fever, nature of fever curve, apparent toxicity, and response to antipyretic have not be found to be helpful.
- Unintentional weight loss
- Drenching night sweats
- Rash
- Myalgias
- Joint pain
- Unilateral retro-orbital headache or jaw claudication
- History of immunosuppression
- Thromboembolic risk factors (previous episodes, prolonged immobility, oral contraceptive pills recent surgeries)
- Medications
- Sick contacts
- Social history:
  1. Alcohol intake
  2. Occupational exposures
  3. Animal exposures
  4. Insect bites
  5. Sexual exposures
  6. Travel history
- Family history:
  1. Autoimmune disorders
  2. Malignancies
  3. Familial Mediterranean fever

PHYSICAL FINDINGS

- HEENT (head, ears, eyes, nose, throat): Sinus tenderness, dental abscesses, funduscopic lesions
- Neck: Adenopathy, palpable thyroid
- Lungs: Auscultate for rales
- Heart: Murmur
- Abdomen: Organomegaly
- Rectal: Prostate tenderness
- Pelvic: Cervical motion tenderness, fundal or adnexal masses or pain, inguinal adenopathy
- Extremities: Clubbing, splinter hemorrhages, tenderness or fluctuance at IV access site
- Musculoskeletal: Joint effusions
- Skin: Rashes, wounds

LABORATORY TESTS

- Initial laboratory testing:
  1. Complete blood count with differential
  2. Comprehensive metabolic panel
  3. Inflammatory markers (erythrocyte sedimentation rate [ESR], C-reactive protein)
  4. Urinalysis
  5. Lactate dehydrogenase
  6. Blood cultures
  7. Thyroid-stimulating hormone
  8. HIV antibody testing
- Consider:
  1. HIV viral load
  2. Hepatitis serologies
  3. TB testing (purified protein derivative or interferon gamma release assay)
  4. Testing for endemic fungal infections (based on geographic location and exposure)
  5. Peripheral smear (thick and thin)
  6. Creatine kinase
  7. Ferritin
  8. Antinuclear antibody testing
  9. Rheumatoid factor
  10. Serum protein electrophoresis
  11. Lumbar puncture
  12. Biopsy (based on clinical and laboratory findings)
- May need to repeat tests at regular intervals until diagnosis is established

IMAGING STUDIES

- Initial:
  1. CXR
  2. Abdominal imaging (CT or ultrasound [US])
- Consider:
  1. Venous duplex imaging
  2. Fluorodeoxyglucose (FDG)-PET
     a. Anatomic localization of focally increased FDG uptake
     b. Consider when initial workup negative and no clear diagnostic clues

TABLE 3 Examples of Subtle Physical Findings Having Special Significance in Patients with Fever of Undetermined Origin

Body Site	Physical Finding	Diagnosis
Head	Sinus tenderness	Sinusitis
Temporal artery	Nodules, reduced pulsations	Temporal arteritis
Oropharynx	Ulceration	Disseminated histoplasmosis
	Tender tooth	Periapical abscess
Fundi or conjunctivae	Choroid tubercle	Disseminated granulomatosis*
	Petechiae, Roth spot	Endocarditis
Thyroid	Enlargement, tenderness	Thyroiditis
Heart	Murmur	Infective or marantic endocarditis
Abdomen	Enlarged iliac crest lymph nodes, splenomegaly	Lymphoma, endocarditis, disseminated granulomatosis*
Rectum	Perirectal fluctuance, tenderness	Abscess
	Prostatic tenderness, fluctuance	Abscess
Genitalia	Testicular nodule	Periarteritis nodosa
	Epididymal nodule	Disseminated granulomatosis
Lower extremities	Deep venous tenderness	Thrombosis or thrombophlebitis
Skin and nails	Petechiae, splinter hemorrhages, subcutaneous nodules, clubbing	Vasculitis, endocarditis

*Includes tuberculosis, histoplasmosis, coccidioidomycosis, sarcoidosis, and syphilis.
From Mandell GL et al (eds): *Mandell, Douglas, and Bennett's principles and practice of infectious diseases*, ed 7, Philadelphia, 2010, Churchill Livingstone.

Rx TREATMENT

- Therapy should be tailored once etiology of FUO has been established.
- When the cause of FUO remains unknown, empiric treatment with broad spectrum antibiotics should be reserved for patients who are severely ill.

DISPOSITION

- Prognosis is determined primarily by the underlying disease.
- FUO patients who remain undiagnosed after an extensive evaluation generally have a favorable outcome.

REFERRAL

To an infectious disease specialist, hematologist, or rheumatologist if no diagnosis after thoughtful workup

Fever of Unknown Origin (Patient Information)

AUTHORS: **Alexandra Abrams-Downey, MD,** and **Erna Milunka Kojic, MD**

TABLE E2 Approach to Management of Fever and Neutropenia

History and Physical Findings	Indicated Modifications in Antimicrobial Coverage or Diagnostic Test
Fever during neutropenia, stable patient	*Escalation approach:* Antibiotic monotherapy with an antipseudomonal β-lactam agent in hemodynamically stable patients with mild to moderate burden of illness; if the patient is receiving antibiotic prophylaxis, then empiric therapy must be based on an agent of a class different from that used for prophylaxis (e.g., if the patient is receiving fluoroquinolone-based prophylaxis, then switch to a β-lactam–based regimen)
Hypotension, signs of severe sepsis or septic shock	*Deescalation approach:* Initial broad-spectrum antimicrobial coverage with a triple-antibiotic regimen (e.g., carbapenem plus vancomycin plus an aminoglycoside) is recommended; if cultures are negative for gram-positive organisms, consider discontinuing vancomycin after 3 days
Fever that is persistent or recrudescent on or after day 5 of antibiotic therapy	Empiric antifungal therapy: Add an amphotericin B product, an echinocandin, or voriconazole if the patient is not already receiving prophylaxis with a mold-active agent; a CT scan of the chest may help identify fungal infection; consider a CT scan of the chest and frequent galactomannan testing during neutropenia to guide preemptive treatment as an alternative strategy to empiric antifungal treatment
Severe oral or esophageal mucositis	Send a swab for viral (HSV) culture; add antiviral coverage if not already being given; consider antiviral resistance to prophylaxis if esophagitis occurs late in the course of neutropenia; add an antifungal agent for possible *Candida* esophagitis; switch streptococcal coverage to vancomycin; esophagoscopy may be indicated
Catheter exit site or tunnel erythema, tenderness, discharge or cellulitis at any site	Culture any discharge; add vancomycin; for tunnel infection (erythema and tenderness 2 cm above exit site), catheter removal and surgical debridement generally are required
Possible anaerobic infection	Add metronidazole if broad-spectrum antibiotics without activity against anaerobes are being used
Abdominal pain, especially right lower quadrant, suggestive of neutropenic enterocolitis; oropharyngeal, neck or soft tissue swelling	Perform a CT scan of the affected area Supportive care: Avoid surgical intervention if possible in a neutropenic patient
New pulmonary infiltrate	Bronchoscopy (with or without biopsy) is the preferred method for evaluating new infiltrates in high-risk patients Nodular: Add mold coverage with voriconazole, posaconazole, or amphotericin B preparation Alveolar: Broaden gram-negative coverage and add *Legionella* coverage (quinolone or macrolide) Interstitial: Send specimen for diagnostic studies for respiratory viruses, PCP, and herpes viruses, particularly CMV Review patient history for risk factors for tuberculosis or infection with endemic fungi
Upper respiratory symptoms of coryza, congestion during fall or winter	Send nasal wash or swab for respiratory viral studies (e.g., culture, PCR, rapid antigen testing)
Hemorrhagic cystitis	Indicated studies include urine viral culture and BK virus PCR assay (for hematopoietic stem cell transplant recipients)

CMV, Cytomegalovirus; *CT,* computed tomography; *HSV,* herpes simplex virus; *PCP, Pneumocystis jirovecii* pneumonia; *PCR,* polymerase chain reaction.

BASIC INFORMATION

DEFINITION

Fibrocystic breast disease (FBD), now called "fibrocystic breast changes" (FBC), includes benign breast lesions including:

- Microcystic and macrocystic changes
- Fibrosis
- Mild and moderate hyperplasia
- Sclerosing adenosis
- Apocrine metaplasia
- Fibroadenoma
- Papilloma
- Papillomatosis
- Radial scar

Nonmalignant breast lesions can be divided into nonproliferative, proliferative without atypia, and atypical hyperplasia. Nonproliferative lesions such as simple breast cysts are considered not to be at increased risk for breast cancer. Proliferative lesions, including ductal hyperplasia, intraductal papillomas, sclerosing adenosis, radial scars, and fibroadenomas, are considered markers for a small increased risk of progressing to breast cancer, and patients should be counseled on risk reduction.

SYNONYMS

Cystic changes
Chronic cystic mastitis
Fibrocystic breast changes
Mammary dysplasia
Fibrocystic mastopathy
Diffuse cystic mastopathy

ICD-10CM CODES

N60.01 Solitary cyst of right breast
N60.02 Solitary cyst of left breast
N60.09 Solitary cyst of unspecified breast
N60.11 Diffuse cystic mastopathy of right breast
N60.12 Diffuse cystic mastopathy of left breast
N60.19 Diffuse cystic mastopathy of unspecified breast
N60.3 Fibrosclerosis

EPIDEMIOLOGY & DEMOGRAPHICS

- FBC affects 30% to 60% of reproductive-age women.
- Most commonly seen in women ages 30 to 50 yr.

ETIOLOGY

The cause of FBC is unknown but is thought to be influenced by reproductive hormones, estrogen in particular.

- Because it is found in the majority of healthy breasts, it is regarded as a nonpathologic process.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

See Table E1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Lumpy or ropey breast texture
- Nodular areas
- Tenderness of breasts and/or nipples
- Dominant mass more often in the upper outer quadrants
- Symptoms tend to be affected by changes in the menstrual cycle.
- Symptoms can be aggravated in postmenopausal women who initiate hormone therapy
- Nipple discharge

For differentiation of breast masses, see Table 2. Characteristics of breast masses suspect for cancer (90% sensitivity, 40% to 60% specificity) are:

- Fixed mass
- Poorly defined mass
- Hard (scirrhous) mass

WORKUP

- Rule out breast carcinoma if breast mass, thickening, discharge, and/or pain are present.
- Perform biopsy of suspected area for histologic confirmation.

IMAGING STUDIES

Mammography and ultrasound studies required:

- For mammographic changes (suspicious densities, microcalcifications [Fig. E1], architectural distortion): Careful evaluation, including possibly biopsy to exclude breast cancer
- Ultrasound study (Fig. E2): To evaluate the presence of a solid vs. cystic mass
- MRI is not recommended for routine evaluation of breast pain or fibrocystic changes

TABLE 2 Differentiation of Breast Masses

Characteristic	Cystic Disease	Benign Adenoma	Malignant Tumor
Patient age	25-60 yr	10-55 yr	25-85 yr
Number	One or more	One	One
Shape	Round	Round	Irregular
Consistency	Elastic, soft to hard	Firm	Stony hard
Delimitation	Well delimited	Well delimited	Poorly delimited
Mobility	Mobile	Mobile	Fixed
Tenderness	Present	Absent	Absent
Skin retraction	Absent	Absent	Present

From Swartz MH: *Textbook of physical diagnosis,* ed 7, Philadelphia, 2014, WB Saunders.

TREATMENT

NONPHARMACOLOGIC THERAPY

Treatment is symptomatic:

- Reassurance
- Supportive bra
- OTC pain medications including NSAIDs and Tylenol
- Reduced intake of methylxanthines (coffee, chocolate), although this is not as effective as previously thought
- Decreasing vitamin E or salt has not proved to be effective
- Periodic physician examination to monitor patients with FCD who have pronounced nodular features
- Aspiration for palpable or symptomatic cysts (NOTE: Cysts often recur; repeat aspiration is not always required unless pain is a problem)

PHARMACOLOGIC TREATMENT

For breast pain:

- Danocrine (Danazol): This is the only FDA-approved drug for breast pain. Moderate success has been reported, but the side effect profile is significant due to androgenic effects.
- Bromocriptine: The medication inhibits prolactin, and its effects are better than a placebo, but side effects such as lightheadedness and gastrointestinal symptoms limit its use.
- Tamoxifen: This has been found to reduce breast pain in 70% of affected women with cyclic breast pain, but the side effects of hot flashes and vaginal dryness interfere with compliance.
- Pharmacologic therapy is usually tapered down after 3 to 6 mo of treatment.

FOLLOW-UP

- Evaluate carefully to exclude breast cancer; then offer reassurance and periodic reevaluation as required.
- Regular self-examination, annual physician examination.

REFERRAL TO BREAST SURGEON

- For further evaluation and/or biopsy if suspicious changes are associated with FBC (including progression of dominant mass or thickening, persistent or bloody nipple discharge, or suspicious mammographic changes or lesions)
- To alleviate anxiety associated with breast symptoms or changes

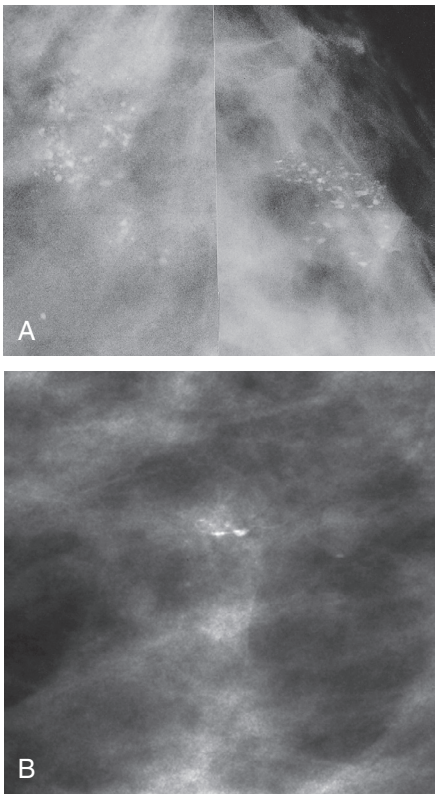

FIG. E1 Fibrocystic change. A, On the CC view, the calcifications appear as round "smudge" shadows. **B,** On the lateral view, 'teacups' representing the layering of calcific material in the dependent portion of microcysts are seen. (From Adam A et al: *Grainger & Allison's diagnostic radiology*, ed 5, 2007, Churchill Livingstone; Sutton D: *Textbook of radiology and imaging*, ed 7, 1998, Churchill Livingstone; and Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, 2019, Elsevier.)

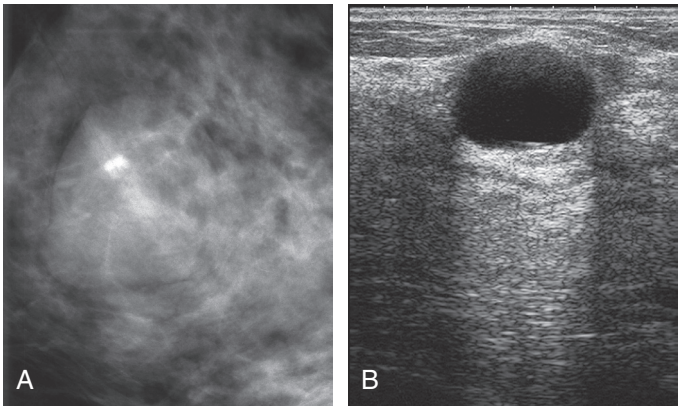

FIG. E2 Cyst. A, A well-defined, rounded mass with an associated lucent halo. **B,** Ultrasound. The absence of internal echoes and posterior enhancement is diagnostic of a cyst. (From Adam A et al: *Grainger & Allison's diagnostic radiology*, ed 5, 2007, Churchill Livingstone; and Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, 2019, Elsevier.)

BASIC INFORMATION

DEFINITION

Fibromyalgia (FM) is a syndrome characterized by chronic, widespread musculoskeletal pain without evidence of soft tissue inflammation. Key features include fatigue, sleep disruption, cognitive disturbance, and psychiatric and somatic symptoms. Research suggests that FM is a disorder of pain regulation, which is often classified as a form of central sensitization.

SYNONYMS

"Fibrositis" is a term that is no longer used, because there is no evidence of connective tissue inflammation in FM.

FM

ICD-10CM CODE
M79.7 Fibromyalgia

EPIDEMIOLOGY & DEMOGRAPHICS

Worldwide, the prevalence of FM is estimated to be between 2% and 8%, and it increases with age. In the U.S., FM is the most common cause of musculoskeletal pain in women aged 20 to 55 yr. Using the 2010 American College of Rheumatology (ACR) diagnostic criteria for FM, the female:male ratio is approximately 2:1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients with FM often report the following symptoms:

- Chronic (>3 mo) widespread (affecting both sides of the body, above and below the waist, and involving the axial spine) musculoskeletal pain
- Cognitive disturbances
- Fatigue and sleep disturbances (e.g., unrefreshed sleep, easy fatigability)
- Psychiatric symptoms (e.g., anxiety, depression)
- Headache (present in more than half of patients with FM; this includes migraine and tension-type headaches)
- Paresthesias
- Associated disorders: Irritable bowel syndrome, interstitial cystitis/painful bladder syndrome

On physical examination, patients with FM may have tenderness in particular soft tissue locations called tender points. Examination of tender points requires that the examiner be familiar with the areas to palpate and that they apply enough pressure (4 kg/cm^2 or enough pressure to whiten the nail bed of the fingertips of the examiner).

ETIOLOGY

Although the exact cause of FM is unknown, its etiology is thought to be multifactorial:

- Genetic and environmental factors may play a role. Evidence suggests that both the ascending and descending pain pathways operate abnormally, resulting in central amplification of pain signals. Familial associations of FM provide strongest evidence that reflect both these factors.
- In those predisposed, FM may be precipitated by stressful events such as abuse, injury from accidents, illnesses (including autoimmune disorders), infections, surgical procedures, and psychological stressors.
- Psychosocial, neuroendocrine, hormonal, and sociocultural factors also influence symptom expression.

PATHOGENESIS

Much remains to be discovered about the pathogenesis of FM, even though significant advances have been made in our understanding of this syndrome over the past few decades. Researchers have shown that biochemical, metabolic, and immunoregulatory abnormalities exist in patients with FM. Hence, this condition is now believed to be neurosensory in nature.

- Augmented pain and sensory processing is a hallmark, resulting in diffuse pain, allodynia (pain brought on by nonpainful stimuli), and hyperalgesia (more intense and prolonged pain perception).
- Afflicted persons show altered physiologic responses to painful stimulation at spinal and supraspinal levels.
- Brain neuroimaging studies found differences in brain structure, neurochemical concentrations, and functional brain networks in FM compared with control subjects. PET scans have revealed widespread activation of glial cells in the cortex, particularly in the frontal and parietal lobes.
- Pain augmentation may also result from a loss of tonic inhibition by descending inhibitory pathways from the brain to the spinal cord.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The presence of any of the disorders mentioned below does not necessarily exclude a diagnosis of FM because it may coexist with many conditions:

- Other functional somatic or "central sensitivity" syndromes: Myofascial pain, chronic fatigue syndrome, irritable bowel syndrome, headache/migraines, chronic pelvic and bladder pain disorders, and temporomandibular disorder
- Disorders that can mimic FM and must be ruled out include metabolic (e.g., hypothyroidism), infectious, and neurologic disorders. Arthritis and rheumatic diseases (e.g., rheumatoid arthritis, systemic lupus erythematosus, osteoarthritis, Sjögren syndrome)
- Myalgias and other muscle disease (e.g., inflammatory and metabolic myopathies)
- Mood and anxiety disorders
- Sleep disorders (e.g., sleep apnea, restless leg syndrome)
- Neurologic disorders
- Medications: Statin-induced muscle pain, opioid-induced hyperalgesia

WORKUP

A thorough history, physical examination, and appropriately selected laboratory or imaging studies can usually differentiate FM from connective tissue or other systemic diseases.

- Chronic (>3 mo) widespread pain is the hallmark symptom of FM, but fatigue, tenderness, depression/anxiety, nonrestorative sleep, cognitive difficulties (the so-called "fibrofog"), and functional impairment are other key symptoms.
- The 1990 ACR FM Classification Criteria were used for clinical studies:
  1. Chronic, widespread pain in all four quadrants of the body and the axial skeleton
  2. Pain on digital palpation of at least 11 of 18 tender points
- The 2010 ACR diagnostic criteria for FM do not require a tender point examination; other disorders that would otherwise explain the musculoskeletal pain must be excluded (Table 1).
- A diagnostic screening tool (Fibromyalgia Diagnostic Screen) developed by Arnold and colleagues was found to accurately screen for FM. This tool includes a patient self-reported questionnaire and an abbreviated physical examination with targeted lab tests.
- The most recent FM diagnostic criteria are by ACTION-APS Pain Taxonomy (AAPT), an international working group. To fulfill AAPT criteria for FM, a patient is required to have a history of at least 3 mo of widespread pain in at least 6 of 9 possible pain sites, and moderate to severe sleep disturbance or fatigue.

LABORATORY TESTS

- Selective use of ancillary tests complements the history and physical examination in the diagnosis of FM. Testing should be highly focused on the exclusion of FM mimickers or suspected concurrent diseases.
- Complete blood cell count, routine chemistries, thyroid-stimulating hormone (TSH), 25-hydroxy vitamin D level (low levels can cause muscle pain), vitamin B^{12} level (low levels can cause fatigue and pain), iron studies (low levels can cause fatigue and depressive symptoms), and magnesium levels (low levels can cause muscle spasms).
- Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) are generally normal.
- Routine testing for antinuclear antibody (ANA) and/or rheumatoid factor should be avoided unless history and physical examination suggest an autoimmune disease.

TREATMENT

GENERAL RX

The goal in treating patients with fibromyalgia is to reduce the main symptoms of the syndrome (musculoskeletal pain, fatigue, depression, anxiety, poor sleep).

- Challenging to treat; best approach may be combination of drug and nondrug therapies.

TABLE 1 2010 Fibromyalgia Diagnostic Criteria

Criteria

A patient satisfies diagnostic criteria for fibromyalgia if the following three conditions are met:

1. Widespread pain index (WPI) 7 and symptom severity (SS) scale score of 5 or WPI 3-6 and SS scale score of 9.
2. Symptoms have been present at a similar level for at least 3 mo.
3. The patient does not have a disorder that would otherwise explain the pain.

Ascertainment

1. WPI: Note the number of areas in which the patient has had pain over the past wk. In how many areas has the patient had pain?

Score will be between 0 and 19.

Shoulder girdle, left	Hip (buttock, trochanter), left	Jaw, left	Upper back
Shoulder girdle, right	Hip (buttock, trochanter), right	Jaw, right	Lower back
Upper arm, left	Upper leg, left	Chest	Neck
Upper arm, right	Upper leg, right	Abdomen	
Lower arm, left	Lower leg, left		
Lower arm, right	Lower leg, right		

2. SS scale score:
   Fatigue
   Waking unrefreshed
   Cognitive symptoms

For the each of the three symptoms above, indicate the level of severity over the past week using the following scale:
0, No problem
1, Slight or mild problems, generally mild or intermittent
2, Moderate, considerable problems, often present at a moderate level
3, Severe: Pervasive, continuous, life-disturbing problems

Considering somatic symptoms in general, indicate whether the patient has:*
0, No symptoms
1, Few symptoms
2, A moderate number of symptoms
3, A great deal of symptoms

The SS scale score is the sum of the severity of the three symptoms (fatigue, waking unrefreshed, cognitive symptoms) plus the extent (severity) of somatic symptoms in general. The final score is between 0 and 12.

*Somatic symptoms that might be considered include muscle pain, irritable bowel syndrome, fatigue or tiredness, thinking or remembering problem, muscle weakness, headache, pain or cramps in the abdomen, numbness or tingling, dizziness, insomnia, depression, constipation, pain in the upper abdomen, nausea, nervousness, chest pain, blurred vision, fever, diarrhea, dry mouth, itching, wheezing, Raynaud phenomenon, hives or welts, ringing in ears, vomiting, heartburn, oral ulcers, loss of or change in taste, seizures, dry eyes, shortness of breath, loss of appetite, rash, sun sensitivity, hearing difficulties, easy bruising, hair loss, frequent urination, painful urination, and bladder spasms.

Adapted from Wolfe F et al: The American College of Rheumatology preliminary diagnostic criteria for fibromyalgia and measurement of symptom severity, *Arthritis Care Res* 62:600-610, 2010.

- Nonpharmacologic (Table 2): Strong evidence to support exercise (aerobic, strengthening, and stretching exercises; tai chi; yoga), cognitive behavioral therapy, physical therapy, and patient education (e.g., regarding the disease, importance of good sleep and hygiene).
- FM can be due to abnormalities in many different neurotransmitter systems; thus, approaches and treatment responses may vary.
- Pharmacologic therapies for fibromyalgia are summarized in Table 3.
- Best evidence for tricyclics (low-dose amitriptyline, cyclobenzaprine), serotonin-norepinephrine reuptake inhibitors (milnacipran, duloxetine), gabapentinoids (gabapentin, pregabalin).
- Second-tier drug classes include SSRIs.
- "Start low, go slow" approach is best to avoid side effects, which are common. Medication adherence is generally poor.
- There is no evidence that acetaminophen, NSAIDs or corticosteroids are effective in FM.
- The only analgesic that has demonstrated some efficacy in FM has been tramadol; can consider for treatment-resistant cases.
- Avoid narcotic use. Opioid use and abuse may aggravate chronic widespread pain.

DISPOSITION

- The pain and symptoms of FM can wax and wane, vary in physical location and in intensity day-to-day; many patients continue to have chronic pain and fatigue regardless of therapy.
- Disability rates vary from 10% to 30%.

REFERRAL

Referral to rheumatology, neurology, mental health professionals, physical medicine and rehabilitation, including PT. Multidisciplinary team approach is generally most helpful.

PEARLS & CONSIDERATIONS

- Fibromyalgia is a neurosensory disorder whereby affected individuals have abnormal central nociceptive processing.
- Diagnosis is based on the presence of chronic musculoskeletal pain in the absence of physical or laboratory evidence of inflammation and in the absence of any other condition that would explain the symptoms.
- Treatment options are varied, but a combination of drug and nondrug options is likely to provide optimal results.
- Myofascial pain syndrome may represent a localized form of FM. It is associated with trigger points (rather than tender points as seen in FM). Some patients with myofascial pain syndrome may progress to FM.

COMMENTS

FM occurs frequently in patients with some rheumatic diseases, such as rheumatoid arthritis, ankylosing spondylitis, and systemic lupus erythematosus, in which prevalence of FM may reach 20%.

Fibromyalgia (Patient Information)

AUTHOR: **Nadine Mbuyi, MD**

TABLE 2 Nonpharmacologic Therapies for Fibromyalgia

Treatment	Cost	Specifics	Evidence Level	Side Effects	Suggestions
Patient education	Low	Incorporate principles of self-management, including a multimodal approach.	1, A		• After initial diagnosis, spend several visits (or use separate educational sessions) to explain the condition and set treatment expectations.
Graded exercise	Low	Aerobic exercise has been best studied, but strengthening and stretching also have been shown to be of value.	1, A	Worsening of symptoms when program is begun too rapidly	• Counsel patients to "start low, go slow." • For many patients, focusing first on increasing daily "activity" is more helpful before actually starting exercise.
Cognitive behavioral therapy (CBT)	Low	Pain-based CBT programs have been shown to be effective in one-on-one settings, small groups, and via the Internet.	1, A	No significant side effects of CBT per se, but patients' acceptance is often poor when they view this as a "psychological" intervention	• Internet-based programs are gaining acceptance and are more convenient for working patients.
Complementary and alternative medicine (CAM) therapies	Variable	Most CAM therapies have not been rigorously studied.	1, A	Generally safe	• There is emerging evidence that CAM treatments such as tai chi, yoga, balneotherapy, and acupuncture might be effective. • Allowing patients to choose which CAM therapies to incorporate into an active treatment program can increase self-efficacy.
CNS neurostimulatory therapies		Several different types of CNS neurostimulatory therapies have been shown to be effective in FM and other chronic pain states.		Headache	• These treatments continue to be refined as we learn about optimal stimulation targets, "dosing," and so on.

CNS, Central nervous system; *FM,* fibromyalgia.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

TABLE 3 Pharmacologic Therapies for Fibromyalgia

Treatment	Cost	Specifics	Evidence level	Side Effects	Suggestions
Pharmacologic therapies		Pharmacologic therapy is best chosen based on the predominant symptoms and initiated in low dose with slow dose escalation.	5, Consensus		• Some practitioners find that getting patients on a drug regimen that helps improve symptoms before initiating nonpharmacologic therapies can help improve compliance.
Tricyclic compounds		• Amitriptyline 10-70 mg qhs • Cyclobenzaprine 5-20 mg qhs	1, A	Dry mouth, weight gain, constipation, "groggy" or drugged feeling	• When effective, can improve a wide range of symptoms, including pain, sleep, bowel, and bladder symptoms. • Taking these drugs several hours before bedtime improves side effect profile.
Serotonin norepinephrine reuptake inhibitors	Duloxetine is generic, milnacipran not	• Duloxetine, 30-120 mg/day • Milnacipran, 100-200 mg/day	1, A	Nausea, palpitations, headache, fatigue, tachycardia, hypertension	• Warning patients about transient nausea, taking with food, and slowly increasing dose can increase tolerability. • Milnacipran might be slightly more noradrenergic than duloxetine and thus potentially more helpful for fatigue and memory problems, but it is also more likely to cause HTN.

TABLE 3 Pharmacologic Therapies for Fibromyalgia—cont'd

Treatment	Cost	Specifics	Evidence level	Side Effects	Suggestions
Gabapentinoids	Gabapentin is generic, pregabalin not	• Gabapentin 800-2400 mg/day in divided doses • Pregabalin up to 600 mg/day in divided doses	1, A	Sedation, weight gain, dizziness	• Giving most or all of the dose at bedtime can increase tolerability.
γ-Hydroxybutyrate	Available for treating narcolepsy, cataplexy	GHB 4.5-6.0 g per night in divided doses	1, A	Sedation, respiratory depression, and death	• Shown to be efficacious but not approved by U.S. FDA because of safety concerns.
Low-dose naltrexone	Low	4.5 mg/day	Two small single center RCTs		
Cannabinoids	NA	Nabilone 0.5 mg PO qhs-1.0 mg bid	1, A	Sedation, dizziness, dry mouth	• No synthetic cannabinoid is approved in the U.S. for treatment of pain.
Selective serotonin reuptake inhibitors (SSRIs)	SSRIs that should be used in FM (see Suggestions) are all generic	Fluoxetine, sertraline, paroxetine	1, A	Nausea, sexual dysfunction, weight gain, sleep disturbance	• Older, less selective SSRIs may have some efficacy in improving pain, especially at higher doses that have more prominent noradrenergic effects. • Newer SSRIs (citalopram, escitalopram, desvenlafaxine) are less effective or ineffective as analgesics.
NSAIDs		• No evidence of efficacy • Can be helpful to treat comorbid "peripheral pain generators"	5, D	GI, renal, and cardiac side effects	• Use the lowest dose for the shortest period of time to reduce side effects.
Opioids		• Tramadol with or without acetaminophen, 50-100 mg every 6 hours • No evidence of efficacy for stronger opioids	5, D	Sedation, addiction, tolerance, opioid-induced hyperalgesia	• There is increasing evidence that opioids are less effective for treating chronic pain than previously thought, and their risk-benefit profile is worse than other classes of analgesics.

bid, Twice a day; *FDA,* U.S. Food and Drug Administration; *FM,* fibromyalgia; *GHB,* gammahydroxybutyrate; *GI,* gastrointestinal; *HTN,* hypertension; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PO,* oral; *qhs,* at bedtime; *RCT,* randomized controlled trial.

Fifth Disease (Parvovirus B19 Infection) PTG

BASIC INFORMATION

DEFINITION

Parvovirus B19 is a small, nonenveloped ssDNA virus that belongs to the *Erythrovirus* genus of the Parvoviridae family. It was first discovered in 1975 when units of blood were being screened for hepatitis B and was read as a false-positive result (sample 19 in panel B). It causes a spectrum of human disease, ranging from asymptomatic to fatal depending on the underlying host. Classically, it has been associated with erythema infectiosum (EI), or "fifth disease," the fifth in a series of six viral exanthems that commonly affect school-aged children and are named in order of the dates they were first described. In addition, parvovirus B19 causes a variety of clinical manifestations in fetuses, adults, and the immunocompromised.

SYNONYMS

Parvovirus B19
Erythema infectiosum
Fifth disease

ICD-10CM CODE
B08.3 Erythema infectiosum [fifth disease]

EPIDEMIOLOGY & DEMOGRAPHICS

Parvovirus B19 infection occurs worldwide. Humans are the only known hosts.

INCIDENCE: Between 1% and 9% of pregnancies are affected by B19 infection. During B19 epidemics, approximately 20% of susceptible school staff members or child care personnel will become infected. The infection rate of household contacts may be as high as 50%.

PEAK INCIDENCE: In the U.S., B19 infection occurs more frequently between late winter and early summer, often in cycles of local epidemics that peak every 4 to 10 yr.

PREVALENCE: The percentage of people with protective IgG antibodies to parvovirus B19 increases with age. Approximately 15% of school-aged children and 50% to 80% of adults have protective antibody titers. Half of women of childbearing age lack antibodies to B19, as do 30% to 40% of pregnant women.

PREDOMINANT AGE: 5 to 18 yr old

RISK FACTORS:

- Exposure to school-aged children
- Immunosuppression
- Congenital or acquired hematologic abnormalities
- Blood transfusion
- Tissue transplantation
- Vertical transmission from infected mother to fetus

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The clinical presentation comprises a wide spectrum and is influenced by the infected person's age and hematologic and immunologic status. Among immunocompetent individuals, approximately 25% of those infected are asymptomatic, 50% have nonspecific flulike symptoms, and 25% have the classic symptoms of B19 infection, including rash and/or arthralgias.

Five typical clinical syndromes are associated with parvovirus B19 infection:

- Fifth disease/erythema infectiosum (EI)
  1. EI is most often seen in children, although it can also occur in adults. EI is characterized by a bright red, nontender rash most prominent on the cheeks, with a circumoral pallor producing the classic "slapped face" appearance (Fig. E1), which is often followed by a reticular, lacelike rash on the trunk and extremities (Figs. E2 and E3). This is typically a transient, self-limited illness that begins with a prodrome of flulike symptoms such as fever, malaise, myalgias, coryza, headache, nausea, and diarrhea. The malar rash occurs once viremia has resolved and antibody production has occurred, as it is thought to be secondary to immune complex deposition.
- Arthropathy
  1. Acute polyarthralgias and polyarthritis are more commonly seen in adults (especially women) and typically involve symmetric small joints of the extremities. The arthritis is nonerosive. Joint symptoms usually resolve within 3 wk but may rarely become persistent or recurrent. A rash develops in 75% of infected adults, but less than 20% have the classic "slapped face" rash seen in EI. The rash may be exacerbated by changes in temperature, sunlight, exercise, or emotional stress.
- Transient aplastic crisis (TAC)
  1. TAC occurs in individuals with hematologic disorders causing increased red blood cell destruction (e.g., sickle cell disease) or decreased red cell production (e.g., iron deficiency anemia). Patients with TAC present with pallor, weakness, and lethargy due to severe anemia, often requiring transfusion. TAC is most often self-limited and usually resolves in 1 to 2 wk.
- Fetal infection leading to nonimmune hydrops fetalis, intrauterine fetal death, or miscarriage
  1. Pregnant women with B19 infection have a 30% chance of fetal transmission. The risk of fetal loss is 5% to 10% and greatest when fetal infection occurs in the first 20 wk of gestation. Parvovirus has not been shown to cause congenital anomalies.
- Pure red cell aplasia in immunocompromised individuals
  1. Chronic infection and severe, sometimes life-threatening anemia have been described in immunocompromised patients, including those with leukemia and other cancers, HIV, congenital immunodeficiency, and tissue transplantation.

Other manifestations:

- Additional skin findings have been reported, including petechial, papular-purpuric gloves-and-socks syndrome (PPGSS), which is an uncommon manifestation of B19 infection. It begins with painful erythema and induration of the hands and feet that then progresses to an erythematous exanthem with a distinct margin at the wrist and ankle joints. Skin changes may further progress to petechia, purpura, and bulla with skin sloughing. PPGSS is seen mainly in young adults and usually resolves in 1 to 3 wk.
- B19 has also been reported in association with a wide range of diseases and clinical manifestations including chronic arthritis, vasculitis, myocarditis, immune thrombocytopenia, neutropenia, nephritis, lymphadenitis, meningitis, encephalitis, hemophagocytic syndrome, and fulminant liver disease. A causal role for B19 in these illnesses has yet to be established.

ETIOLOGY, INFECTIVITY, & TRANSMISSION

- B19 preferentially infects, replicates in, and is directly cytotoxic to erythroid progenitor cells, which may result in profound anemia or pure red cell aplasia.
- Viremia and the period of greatest infectivity occur 5 to 10 days after exposure and last about 1 wk in immunocompetent individuals,

FIG. E1 Erythema infectiosum. Erythema of the bilateral cheeks, which has been likened to a "slapped cheeks" appearance. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E2 Erythema infectiosum. Reticulate erythema on the upper arm of a patient with erythema infectiosum. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Erythema infectiosum. Patchy erythema with reticulate changes of the inner thigh in a patient with erythema infectiosum. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

after which time antibody production begins and typical symptoms of rash and arthralgias manifest.
- Modes of transmission include contact with respiratory tract secretions, vertical transmission from mother to fetus, percutaneous exposure to blood, and transfusion of blood products.
- Because of its nonenveloped capsid, parvovirus B19 is heat stable and difficult to inactivate with solvent detergents, leading to its potential to contaminate blood products.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Depending on the clinical presentation, differential includes:

- Erythema infectiosum
- Roseola, rubella, measles, group A strep, and other childhood viral exanthems
- Infectious mononucleosis
- Acute HIV infection
- Drug eruption
- Acute polyarthritis
- Juvenile rheumatoid arthritis (Still disease)
- Transient arthritis secondary to an acute viral infection

WORKUP

- Most patients with parvovirus B19 infection do not require laboratory testing because symptoms are mild and resolve over 5 to 7 days.
- Diagnosis can be made by the typical clinical presentation of EI in well children.
- Laboratory tests may be required for confirmation in immunosuppressed populations, those with severe anemia or transient aplastic crisis (TAC), and pregnant women.
- People who are at risk for severe parvovirus complications and are at high risk for exposure might benefit from antibody testing to determine whether they are immune to parvovirus.

LABORATORY TESTS

- Complete blood count (CBC) and reticulocyte count: Reticulocyte count and hematocrit indicate the clinical severity of infection. CBC classically shows a normocytic normochromic anemia. Reticulocytes are markedly decreased or absent in pure red blood cell aplasia, rising once neutralizing antibody is produced. White blood cell and platelet counts are typically unchanged.
- Parvovirus B19 IgM and IgG: Parvovirus B19 IgM enzyme immunoassay is widely available and the preferred method of diagnosis in immunocompetent individuals. IgM can be detected within 7 to 10 days of exposure and may persist for several mo. IgG antibodies are detectable about 15 days after exposure and persist for life.
- Parvovirus B19 viral DNA polymerase chain reaction (PCR) is the most sensitive method of detection and is the preferred method for diagnosis in immunocompromised individuals, fetuses, and immunocompetent patients with suspected persistent infection. High titers of viral DNA in serum are indicative of active infection. Rare B19 variants can be under-quantified by some PCR methods. Low levels of B19 DNA may be detected in serum by PCR for mo to yrs after treatment or resolution of disease, and low levels of viral DNA may be found in tissues in patients without active disease.
- Bone marrow biopsy: Bone marrow examination in patients with pure red cell aplasia demonstrates complete or near-complete absence of red cell precursors. Characteristic giant proerythroblasts containing large eosinophilic nuclear inclusions can be seen.
- Fig. E4 illustrates investigations for parvovirus B19 infection in pregnancy.
- Prenatal testing: Fetal nuchal translucency measurement and ductus venosus Doppler velocimetry may indicate the presence of severe fetal anemia. Ultrasound may show fetal edema, ascites, pleural effusions, and cardiomegaly in hydrops fetalis.

Rx TREATMENT

Treatment for fifth disease is generally supportive because the majority of B19 infections are asymptomatic or mild and self-limited. This includes nonsteroidal antiinflammatory drugs for relief of joint symptoms, antipyretics such as acetaminophen for fever, and adequate hydration.

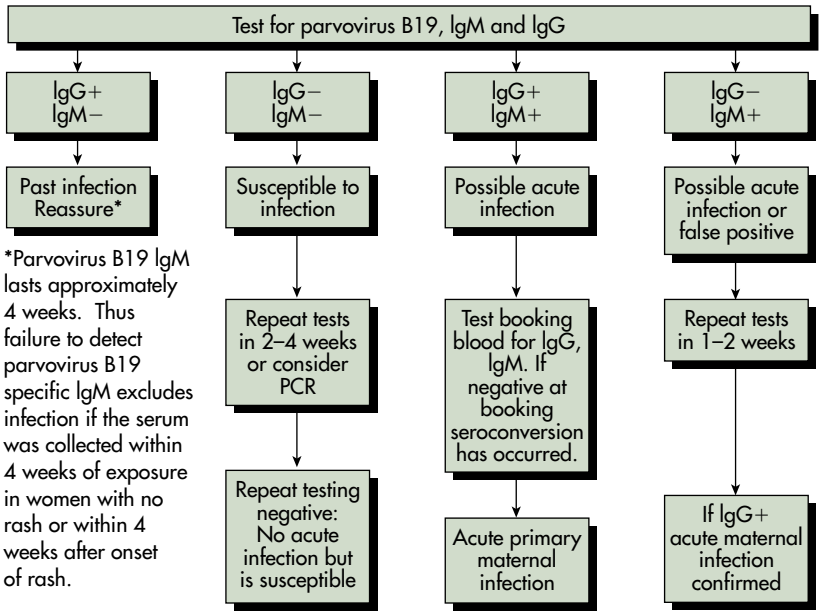

FIG. E4 Investigations for parvovirus B19 infection. (From Stephen G, Gillham J: Fetal infection: a pragmatic approach to recognition and management, *Obstet Gynecol Reprod Med* 22:299-303, 2012.)

- No antiviral drug is available.
- Blood transfusion is often required in cases of severe anemia and pure red cell aplasia until red blood cell (RBC) production returns; intrauterine transfusion may be required in fetal infection.
- Initiation of antiretroviral therapy (ART) has been associated with resolution of B19-induced anemia in HIV-infected patients.
- Bone marrow transplantation has been used in individuals with nonresolving aplastic crisis.
- The mainstay of therapy for fetal hydrops is delivery, which may be followed by resuscitation and ventilation in cases of severe hydrops.

IV immunoglobulin (IVIG) treatment may be considered for immunocompromised patients with chronic B19 infection and chronic anemia and has also been used in certain cases of acute, severe infection.

DISPOSITION

- B19 infection is typically self-limited, with symptoms usually resolving within a few wk and most often only requiring supportive care.
- The illness is contagious in the wk before the rash appears. Once the rash appears, the person with the illness is no longer considered contagious and does not require isolation.
- Patients in whom persistent arthritis with or without joint erosion develops should be evaluated by a rheumatologist.
- In immunocompetent patients, anemia is typically transient with spontaneous resolution and return of RBC production in days to wk. In patients with hematologic abnormalities, however, anemia may be severe and may be the result of transient aplastic crisis or pure red cell aplasia, which warrants immediate hematologic evaluation and transfusion.
- Patients with TAC or chronic parvovirus B19 infection pose a risk for nosocomial spread and, when hospitalized, should be isolated with droplet precautions.
- Patients with chronic infection and anemia may require evaluation for possible IVIG treatment.
- Pregnant women with B19 infection have a 30% risk of fetal transmission; they should undergo close monitoring of fetal health and development and may require fetal transfusion or referral to a tertiary care center for delivery in the case of hydrops fetalis.

REFERRAL

- To hematologist if signs of marrow suppression
- To rheumatologist if signs of severe or erosive arthritis

PEARLS & CONSIDERATIONS

- Generally self-limited disease lasting up to 3 wk in immunocompetent individuals.
- Symmetric arthritis involving small joints is common in adults, whereas facial rash is common in children.
- Can cause severe anemia with or without transient aplastic crisis that may become chronic in patients with hematologic abnormalities, immunocompromise, malignancy, or a history of organ transplantation.
- Infection during pregnancy can cause fetal anemia, hydrops fetalis, or fetal loss.

PREVENTION

- Personal infection control practices including hand hygiene; covering the mouth while sneezing and coughing; not touching the eyes, mouth, or nose; not sharing food and drinks; and avoiding contact with sick persons.
- Droplet isolation precautions for infected immunocompromised patients or those with TAC.
- Testing of plasma pools and blood products: In June 2009, the FDA issued guidance requiring manufacturers to perform parvovirus B19 nucleic acid testing to reduce the possible risk of parvovirus B19 transmission by plasma-derived products.
- Vaccines have not progressed beyond phase I/II clinical trials.

BASIC INFORMATION

DEFINITION

Filariasis is a general term for an infection caused by subcutaneous nematodes (roundworms) of the genera *Wuchereria* and *Brugia,* found in the tropical and subtropical regions of the world. The disease is characterized by acute lymphatic inflammation or chronic lymphatic obstruction associated with intermittent fevers or recurrent episodes of dyspnea and bronchospasm.

SYNONYMS

Lymphatic filariasis
Elephantiasis
Tropical pulmonary eosinophilia

ICD-10CM CODES

B74.0 Filariasis due to *Wuchereria bancrofti*
B74.1 Filariasis due to *Brugia malayi*
B74.9 Filariasis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): In the U.S., the last locale with endemic lymphatic filariasis was Charleston, South Carolina, with no infections seen since the early twentieth century. Zoonotic infections from other *Brugia* spp. have been sporadically reported in North America.
INCIDENCE (GLOBAL): Thanks to mass drug administration campaigns targeted at stopping transmission of infection, prevalence is steadily decreasing globally. However, lymphatic filariasis is endemic in 73 countries; 40 million people have clinical manifestations, 15 million have elephantiasis, and 25 million men have genital swelling (usually hydrocele) from filariasis.
PREDOMINANT SEX: Male
PREDOMINANT AGE: For both males and females, risk is greatest between the ages of 15 and 35 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical manifestations result from acute lymphatic inflammation or chronic lymphatic obstruction.
- Many patients are asymptomatic despite the presence of microfilaremia.
- Episodes of lymphangitis and lymphadenitis are associated with fever, headache, and back pain with painful swellings. Painful localized swelling or acute adenolymphangitis is usually caused by the death of an adult worm.
- Acute funiculitis and epididymitis or orchitis may also be present; all usually resolve within days to wks but tend to recur.
- Chronic infections may be associated with lymphedema, most commonly manifested by hydrocele.
- It is a progressive disease, leading to nonpitting edema and brawny changes that may involve a whole limb.
- Elephantiasis occurs in about 10% of patients, with skin of the scrotum or leg becoming thickened and fissured; the patient is thereafter plagued by recurrent ulceration and infection.
- Chyluria, a condition that develops when lymphatic vessels rupture into the urinary tract, or chylocele may occur.
- Tropical pulmonary eosinophilia can also occur; it is caused by high IgE in response to microfilariae in the lungs and results in nocturnal asthma, fatigue, and weight loss with pulmonary infiltrates on imaging and eosinophilia.

ETIOLOGY

Caused by one of three types of nematode parasite transmitted to humans by mosquitoes:

- *W. bancrofti* (>90% of cases; Fig. E1): Africa (including Egypt), areas of Central and South America, the Pacific Islands, and the Caribbean Basin.
- *B. malayi:* Restricted to India, Malaysia, and other parts of Southeast Asia.
- *B. timori:* Confined to the Indonesian archipelago. After bite of an infected mosquito:
  1. Filarial larvae move into lymphatic vessels and nodes and mature into adult male (2- to 4-cm) and female (4- to 10-cm) worms (Fig. E2). *Wolbachia* bacteria are needed for filarial development.
- After fertilization, the female nematode produces 10,000 or more microfilariae that enter into the bloodstream via the lymphatics.
- Nocturnal periodicity, an increased presence of microfilariae in the circulation during the night when mosquitos are active, is important for diagnosis by blood smear.
- Humans are the definitive hosts.

Acute and chronic inflammatory and granulomatous changes in the lymphatic channels:

- Result from complex interaction of adult worms and host's immune systems

FIG. E1 Microfilaria of *Wuchereria bancrofti* in peripheral blood. (Courtesy Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention. From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

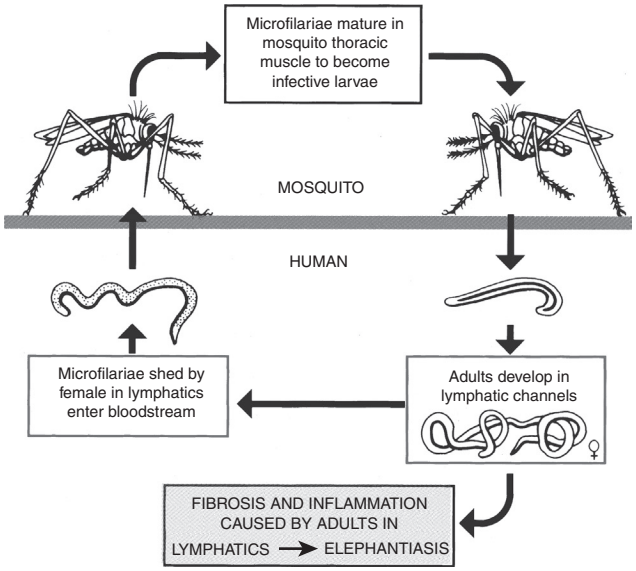

FIG. E2 Lifecycle of lymphatic filariasis. (From Souhami RL, Moxham J: *Textbook of medicine,* ed 4, London, 2002, Churchill Livingstone.)

- Eventually lead to fibrosis and obstruction
- Most likely to develop into obstructive lymphatic disease with recurrent exposure over many yrs, with approximately 30% of those infected going on to develop lymphedema/hydrocele

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Milroy disease, postoperative scarring, and lymphedema of malignancy

WORKUP

Diagnosis is suspected in individuals who have resided in endemic areas for at least 3 to 6 mo or more and complain of recurrent episodes of lymphangitis, lymphadenitis, scrotal edema, or thrombophlebitis, with or without fever.

LABORATORY TESTS

- Demonstration of microfilariae on a blood smear via Giemsa or Wright Stain for definitive diagnosis. Samples drawn at night, especially between 10 PM and 2 AM, have the greatest yield.
- Occasionally, microfilaremia in chylous urine or hydrocele fluid.
- Prominent eosinophilia only during periods of acute lymphangitis or lymphadenitis.
- Serologic tests for antibody, including enzyme-linked immunosorbent assay and indirect fluorescent antibody (often unable to distinguish among the various forms of filariasis or between acute and remote infection).
- Immunoassays (e.g., circulating filaria antigen [CFA]): More successful in antigen detection in patients who are microfilaremic than in those who are amicrofilaremic.

IMAGING STUDIES

- Chest radiography: Reticular nodular infiltrates (tropical pulmonary eosinophilia syndrome).
- In men proven to be microfilaremic, scrotal ultrasonography to aid in the detection of adult worms and "filarial dance sign" may be seen.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Standard of care for elephantiasis:
  1. Elevation of the affected limb
  2. Use of elastic stockings
  3. Local foot care
- General wound care for chronic ulcers and prevention of secondary infection
- Surgical intervention may be necessary for hydrocele

ACUTE GENERAL Rx

- Diethylcarbamazine citrate (DEC) to reduce microfilaremia by 90%.
  1. Effect on adult worms, especially those of the *Wuchereria* species, less certain.
  2. Given in an oral dose of 6 mg/kg PO qd in 3 divided doses × 14 days or 6 mg/kg/day as single PO dose daily × 14 days *plus* doxycycline 200 mg/day × 6 wk (to decrease number of *Wolbachia* and number of microfilaria).
  3. DEC should not be used if coinfection with Loa loa or onchocerciasis is suspected, because of severe adverse reactions, including blindness and death.
- Ivermectin alone or in combination with DEC to decrease microfilaremia. Ivermectin kills the microfilariae but does not kill adult worms.
- Side effects of these drugs include severe hypotensive reactions with dizziness, headache, fever, and vomiting, especially in patients with high microfilarial loads.
- World Health Organization (WHO) recommendation: DEC given as a single dose, alone or (preferably) in combination with ivermectin as treatment in endemic areas.
- Antibacterial agents (a penicillin or cephalosporin) may be indicated to treat coexisting bacterial soft tissue infection (cellulitis or lymphangiitis), which frequently complicates filariasis of the lower extremities.
- Doxycycline for 1 to 2 mo may decrease the number of adult worms and improve lymphatic pathology.
- A recent trial revealed that a single dose of a three-drug regimen of ivermectin, diethylcarbamazine, and albendazole results in a greater clearance of microfilariae than a single dose of a two-drug regimen of diethylcarbamazine plus albendazole.[1]

CHRONIC Rx

- Surgical drainage of hydroceles
- No satisfactory therapy for patients with chyluria

DISPOSITION

Rarely fatal, but the psychological impact of limb and scrotal deformities associated with elephantiasis is substantial

REFERRAL

To a surgeon for management of hydrocele; to a lymphedema therapist when appropriate

PREVENTION

Individuals who intend to travel or reside in endemic areas should be advised to institute preventive measures such as the use of netting and insect repellents containing DEET, especially at night when mosquitos transmitting disease are most active.

BASIC INFORMATION

DEFINITION

Focal seizures are characterized by focal cortical discharges that provoke seizure symptoms related to the area of the brain involved. Focal aware seizures (previously known as simple partial seizures) do not cause impairment of consciousness. However, focal aware seizures can evolve into focal impaired awareness (previously known as complex partial) and/or tonic clonic seizures. In the revised International League Against Epilepsy (ILAE) classification of seizures, the name "partial seizures" has been replaced with "focal seizures."

SYNONYMS

Simple partial seizures
Seizures, partial
Partial seizures

ICD-10CM CODES

G40.0	Localization-related (focal) (partial) idiopathic epilepsy and epileptic syndromes with seizures of localized onset
G40.109	Localization-related (focal) (partial) symptomatic epilepsy and epileptic syndromes with simple partial seizures, not intractable, without status epilepticus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 30 to 50 cases per 100,000 person per yr
PREVALENCE: 5 to 8 cases per 1000 persons
PREDOMINANT SEX AND AGE: No gender preference

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with focal seizures usually have normal physical and neurologic examinations unless secondary due to a structural abnormality such as a stroke, where the patient will have a neurologic exam consistent with the area of CNS structural damage.
- During focal seizures the patients are conscious, but they may have an alteration of awareness. However, if there is spread of the epileptic focus causing secondary generalization, the patient will then lose consciousness and evolve into a generalized tonic clonic seizure. Clues to this progression include a subjective aura before the onset of convulsion, unilateral shaking, and head turning to one side (versive head turning).
- Patients with focal seizures can experience postictal weakness/paralysis that usually resolves within 24 hr (Todd paralysis). However, focal neurologic deficits may also be indicative of a new structural brain lesion.
- Manifestations of focal impaired awareness seizures may include automatisms (semipurposeful behaviors) such as fumbling of fingers or lip smacking.

ETIOLOGY

- Seizures in general are a cardinal sign of cortical neurologic injury.
- The etiology of focal seizures can be either genetic or due to a neurologic injury.
- Frequent causes of focal seizures are tumors, stroke, CNS infections (neurocysticercosis among others), arteriovenous malformations (AVMs), cavernous malformations, traumatic brain injury, cortical dysplasia, and structural abnormalities.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Transient ischemic attack
- Movement disorders
- Psychogenic nonepileptic spells
- Migraines
- The differential diagnosis of nonepileptic events is summarized in Table 1. Table 2 summarizes clinical characteristics that help distinguish epileptic from nonepileptic events

WORKUP

EEG. Ambulatory EEG and/or video EEG recommended for patients with diagnostic uncertainty

LABORATORY TESTS

Routine blood workup (CBC, CMP, glucose, electrolytes) may be considered in appropriate clinical situations.

IMAGING STUDIES

- In the acute setting, a CT scan of the head is high yield to rule out space-occupying lesions.
- MRI of the brain with a defined epilepsy protocol should be performed in all patients with recurrent seizures.

TREATMENT

- Almost all antiepileptic drugs are approved for focal seizures, either in monotherapy or in adjunct. Carbamazepine traditionally has been the standard initial drug treatment for focal seizures. However, newer antiepileptic drugs have better side effect profiles.
- Lamotrigine, levetiracetam, and oxcarbazepine are effective and well-tolerated antiepileptic drugs for treating focal seizures.
- Eslicarbazepine is indicated for the treatment of focal-onset seizures as monotherapy or adjunctive therapy. The recommended initial dose of eslicarbazepine is 400 mg once daily. Increase the dose in weekly increments of 200 mg, based on clinical response and tolerability, to a recommended maintenance dose of 800 to 1600 mg once daily.
- Lacosamide is indicated as monotherapy or adjunctive therapy in patients with focal-onset seizures. The initial recommended dose is 50 mg twice daily; increase at weekly intervals by 50 mg twice daily, up to a recommended maintenance dose of 100 to 200 mg twice daily.
- Patients who continue to have seizures despite a trial of two antiepileptic drugs and adequate doses should be referred for evaluation for epilepsy surgery. Surgical treatments (e.g., temporal lobectomy in mesial temporal sclerosis) may be indicated in refractory cases of focal seizures.

GENERAL Rx

- After a first unprovoked seizure with normal examination, imaging, and EEG, no treatment may be necessary, although patients may elect to undergo treatment.
- According to a recent joint American Academy of Neurology and American Epilepsy Society evidence-based guideline on the management of a first unprovoked seizure in adults, there is strong evidence that the risk of a second seizure is highest in the first 2 yr and ranges from 21% to 45%. This risk is higher for patients with prior brain insults such a traumatic brain injury or stroke or those with epileptiform abnormalities on EEG. Significant brain imaging abnormalities and nocturnal seizures also indicate a more elevated risk of recurrent seizures. Chronic treatment with antiepileptic drugs is indicated for more than

TABLE 1 Differential Diagnosis of Nonepileptic Events

General Medical Conditions
- Transient ischemic attack (TIA)
- Complicated migraine
- Syncope
- Hypoglycemia
- Parasomnia (e.g., rapid eye movement [REM], behavior disorder, or night terrors)
- Narcolepsy
- Myoclonus (from metabolic disturbance)

Psychiatric Causes
- Conversion disorder
- Somatic symptom disorder
- Dissociative disorder
- Panic disorder (simulating focal seizures)

Volitional Deception
- Factitious disorder (goal is to maintain the sick role)
- Malingering (goal is to obtain secondary gain, e.g., disability income)

From Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 2 Clinical Characteristics That Help Distinguish Epileptic from Nonepileptic Events

	Epileptic Seizures	Nonepileptic Seizures/Events
Onset	Sudden onset and offset	Often gradual
Duration	Often <3 minutes	Variable
Perception	May experience olfactory, gustatory, visual hallucination; déjà vu; derealization	May experience auditory hallucinations; paranoia
Eyes during event	Open	Closed
Incontinence	Common	Rare
Awareness	Often impaired; can stay aware during some focal seizures	Variable; may be responsive during parts of the event
Recall of event	None or limited (e.g. aura)	Usually intact
Ictal EEG	Almost always abnormal	Unchanged from baseline
Interictal EEG	Normal or abnormal	Often normal
Tongue bite	Lateral tongue	None or tip of tongue
Injury	May be present	Rarely present (suggestive of serious psychopathology)
Incontinence	May be present	Rare
Postictal state	Confusion or drowsiness is common	Rare
Prolactin	Elevated; or normal	Normal; rarely elevated from baseline

From Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

two unprovoked seizures or in patients with one seizure with abnormal workup. However, moderate evidence supports advising the patient that immediate antiepileptic therapy, compared with delaying treatment until a second unprovoked seizure, is likely to reduce the risk of a seizure recurrence in the next 2 yr. Furthermore, the risk of adverse events with antiepileptic drugs ranges from 7% to 31%, with most of these adverse events being mild and reversible. Thus, the practice guideline suggests that under certain circumstances, adults with one provoked seizure even without high-risk EEG or MRI findings can be treated with antiepileptic drugs because, at least over the next 2 yr, the risk of a recurrent seizure is reduced. Although there is no strong evidence that such treatment improves quality of life, even one seizure can have negative consequences on social and occupational functioning such as driving, making treatment an attractive option for many.

- Recurrent seizures and seizures with abnormal studies require treatment in the form of medicines, consideration of surgery, or with approved medical devices.

DISPOSITION

- Response to treatment often depends on the etiology of the focal seizures.
- Forty-seven percent of patients become seizure free with monotherapy and 67% with polytherapy.
- Patients who do not respond to two drugs should be referred to an epilepsy center for consideration of surgical treatment.
- No driving until seizure free in accordance with local laws and regulations.
- Patients should avoid situations that may cause injuries or accidents in the event of a seizure, such as climbing ladders, swimming unsupervised, or taking baths (rather than showers).
- Many antiepileptic drugs also affect vitamin D absorption or metabolism, prompting attention to patients' bone health.
- All patients with epilepsy are at higher risk for depression and should be screened.

REFERRAL

Patients with epilepsy and seizures should be referred for a consultation by a neurologist, preferably one with a special interest in epilepsy.

PEARLS & CONSIDERATIONS

COMMENTS

- Successful treatment depends on the correct choice of antiepileptic drugs based on patient's gender and comorbidities.
- Valproic acid should be avoided in girls and women with childbearing potential due to the risk of teratogenicity.
- All women of childbearing age taking antiepileptic drugs should take folic acid supplementation (1 to 4 mg/day) for the prevention of neural tube defects. Many antiepileptic drugs interact with oral contraception.

PREVENTION

- Sleep deprivation and alcohol consumption should be avoided.
- Drug compliance is compulsory to prevent seizure recurrence.

PATIENT & FAMILY EDUCATION

- Patient education and information can be obtained at the Epilepsy Foundation: www.epilepsyfoundation.org.
- Patients should be counseled on general seizure precautions such as swimming, bathing, and heights.

BASIC INFORMATION

DEFINITION

Folliculitis is inflammation of the hair follicle as a result of infection, physical injury, or chemical irritation.

SYNONYM

Sycosis barbae

ICD-10CM CODES

L72.9	Follicular cyst of skin and subcutaneous tissue, unspecified
L73.1	Pseudofolliculitis barbae
L73.8	Other specified follicular disorders
L66.2	Folliculitis decalvans
L66.4	Folliculitis ulerythematosa reticulata
L66.3	Perifolliculitis capitis abscedens

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Staphylococcal folliculitis is the most common form of infectious folliculitis; it occurs most commonly in persons with diabetes. Gram-negative folliculitis occurs in patients who have had moderately inflammatory acne for long periods and have been treated with long-term antibiotics such as tetracycline.
PREDOMINANT SEX: Sycosis barbae occurs most frequently in men who have commenced shaving.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The lesions generally consist of painful yellow pustules surrounded by erythema; a central hair is present in the pustules. Furuncles with pus may be present.
- Patients with sycosis barbae may initially present with small follicular papules or pustules that increase in size with continued shaving; deep follicular pustules may occur surrounded by erythema and swelling; the upper lip is frequently involved.
- "Hot tub" folliculitis occurs within 1 to 4 days after the use of a hot tub with poor chlorination. It is characterized by papules and pustules (Fig. E1) with surrounding erythema generally affecting the torso, buttocks, and limbs (Fig. E2).

ETIOLOGY

- Staphylococcus infection (e.g., sycosis barbae), *Pseudomonas aeruginosa* ("hot tub" folliculitis)
- Gram-negative folliculitis (*Klebsiella, Enterobacter, Proteus*) associated with antibiotic treatment of acne
- Chronic irritation of the hair follicle (use of cocoa butter or coconut oil, chronic irritation from workplace)
- Initial use of systemic corticosteroid therapy (steroid acne), eosinophilic folliculitis (AIDS patients), *Candida albicans* (immunocompromised patients)
- *Pityrosporum orbiculare*

FIG. E1 Papules and pustules in hot tub folliculitis. (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pseudofolliculitis barbae (ingrown hairs)
- Acne vulgaris
- Dermatophyte fungal infections
- Keratosis pilaris
- Cutaneous candidiasis
- Superficial fungal infections
- Miliaris

WORKUP

- Physical examination and medical history (e.g., use of hot tub: "hot tub" folliculitis; adolescent patients who have started shaving: sycosis barbae; use of occlusive topical steroid therapy: *Staphylococcus* folliculitis).
- Gram-negative folliculitis in acne patients on prolonged antibiotic treatment manifests with superficial pustules 3 to 6 mm in diameter flaring out from anterior nares or fluctuant, deep-seated nodules.

LABORATORY TESTS

- Generally not necessary.
- Gram stain is useful to identify the infective organisms in infectious folliculitis and to differentiate infectious folliculitis from noninfectious.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Prevention of chemical or mechanical skin irritation
- Glycemic control in diabetics
- Proper chlorination of hot tubs and spas
- Shaving with a clean razor

ACUTE GENERAL Rx

- Cleansing of the area with chlorhexidine and application of saline compresses to involved area.
- Application of 2% mupirocin ointment or 1% retapamulin ointment for bacterial folliculitis affecting a limited area (e.g., sycosis barbae).
- Treatment of severe cases of *Pseudomonas* folliculitis with ciprofloxacin.
- Treatment of *S. aureus* folliculitis with dicloxacillin 250 mg qd for 10 days.
- Isotretinoin is the treatment of choice in gram-negative folliculitis. Amoxicillin or TMS-SMX can be used when isotretinoin is contraindicated or cannot be tolerated.

CHRONIC Rx

- Chronic nasal or perineal *S. aureus* carriers with frequent folliculitis can be treated with rifampin 300 mg bid for 5 days.
- Mupirocin or retapamulin ointment applied to nares bid is also effective for nasal carriers.

DISPOSITION

- Most cases of bacterial folliculitis resolve completely with proper treatment.
- Steroid folliculitis responds to discontinuation of steroids.

PEARLS & CONSIDERATIONS

COMMENTS

Patients should be instructed in good personal hygiene and avoidance of sharing razors, towels, and washcloths.

BASIC INFORMATION

DEFINITION

Food allergies are divided into IgE-mediated and immunologically mediated non-IgE reactions. They include a spectrum of disorders that involve adverse immunologic responses to dietary antigens.

ICD-10CM CODES

T78.0	Adverse food reaction (including anaphylactic shock)
T78.1	Other adverse food reactions, not elsewhere classified
L27.2	Dermatitis due to ingested food
Z91.010	Allergy to peanuts
Z91.011	Allergy to milk products
Z91.012	Allergy to eggs
Z91.013	Allergy to seafood
Z91.018	Allergy to other foods
Z91.02	Food additives allergy status

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Food allergies have a cumulative incidence of 6% to 8% for the first 3 yr of life.

PREVALENCE:

- Overall prevalence is 1% to 2% in general population, ~3.9% to 8% in children.
- Patient self-reported food allergies have a prevalence of 12% to 13%, demonstrating the importance of objective measures in assessing food allergies.
- Nearly 40% of children with food allergy have a history of severe reactions that, if not treated immediately with proper medication, can lead to hospitalization or even death.[1]
- There is insufficient evidence to conclude a racial predilection (Greenhawt, 2013).

GENETICS: Children with parents or close relatives with allergies may have a tendency to become allergic to foods.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- IgE-mediated reactions: (within minutes to a few hours): Pruritus, urticaria or angioedema, atopic dermatitis, GI symptoms, conjunctival injection, sneezing, nasal congestion, rhinorrhea, bronchospasm, and anaphylaxis
- Non–IgE-mediated reactions: Food-induced enterocolitis, celiac disease, Crohn disease, dermatitis herpetiformis, and pulmonary reactions such as Heiner syndrome. These illnesses are discussed separately.
- Signs, symptoms, and presentation reflect specific allergic manifestation, but in food allergies there is a reproducible temporal relationship to ingested food allergens.

ETIOLOGY

Failure to establish tolerance to food antigens. IL-33 mediated epithelial permeability and Th2 skewing result in sensitization to food proteins which are presented to primed T cells. Food processing conditions that may affect allergenic activity are described in Table 1.

[1] Gupta RS et al: The prevalence, severity, and distribution of childhood food allergy in the United States, *Pediatrics* 128(l):e9-e17, 2011.

DIAGNOSIS

- Thorough history (to identify specific food[s], quantity consumed, timing, and nature of reaction) and physical exam should be performed.
- The temporal relationship and reproducibility of the symptoms are most important to establishing the diagnosis.
- A review of ingredient labels may be helpful.
- Confirmatory testing can include skin testing or in vitro testing.
- Skin prick testing (SPT): Positive predictive value <50%, but negative predictive value >95%. Thus a negative skin test effectively rules out an IgE-mediated process.
- In vitro testing: RAST testing: Historically it is less sensitive than skin testing, but sensitivity has improved with cut off points indicating a positive predictive value of 95% for allergies to eggs, milk, peanuts, wheat, and fish.
- Atopy patch test: Used in conjunction with RAST and skin testing in multiallergic children to plan widening the elimination diet. However, it is not recommended in the routine evaluation of food allergies.
- Double-blind, placebo-controlled food challenges are the gold standard test for determining food allergies. These need to be done in a supervised and controlled setting.
- In summary, if the history and lab tests are suggestive of a specific food allergy, that food should be confirmed by SPT, RAST, or food challenge and, once confirmed, eliminated from the diet.

DIFFERENTIAL DIAGNOSIS

- Gastrointestinal disorders
- Irritable bowel syndrome
- Carcinoid syndrome
- Giardiasis
- Structural abnormalities like hiatal hernia, pyloric stenosis, Hirschsprung disease, tracheoesophageal fistula
- Disaccharidase deficiencies: Lactase, sucrase-isomaltase complex, glucose-galactose complex
- Pancreatic insufficiency: Cystic fibrosis
- Gallbladder disease
- Peptic ulcer disease
- Malignancy
- Metabolic disorders
- Galactosemia
- Phenylketonuria
- Pharmacologic-related conditions
- Gustatory rhinitis
- Auriculotemporal syndrome (facial flush from tart food)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Elimination diet should be used in conjunction with nutritional counseling. Fig. 1 illustrates an algorithm for the management of food allergy
- Formula-fed infants: Brief trial of hydrolyzed milk formula as most children with milk allergy–induced skin symptoms will respond to the change of formula. Nonresponders may require amino acid–based formula.
- In older children: Elimination of one to two suspected foods is appropriate for 2 wk or longer and then reintroducing the foods to determine if symptoms recur.

ACUTE GENERAL Rx

- Antihistamines (both H1 and H2 antihistamines), albuterol if wheezing, epinephrine and glucocorticoids in patients with anaphylaxis.
- Patients with documented IgE-mediated reactions should receive and be counseled on the use of epinephrine autoinjector.

NEW TREATMENTS FOR FOOD ALLERGIES

- Oral and sublingual immunotherapy may play a role in management of food allergies, but this is currently under investigation.
- Recombinant vaccines and other immunomodulatory strategies are under development, although monoclonal anti-IgE antibody has shown benefit in adults with peanut allergy.

PEARLS & CONSIDERATIONS

- Eczema that develops in first 6 to 12 mo of life is usually the first manifestation of atopy.
- Egg allergy or sensitization is the strongest recognized predictor of respiratory allergies in children and asthma in adults.
- Consultation with trained dietitian is critical to avoid potentially adverse nutritional consequences in children with multiple food allergies.
- Skin testing is the preferred method for identifying food-specific IgE. RAST is useful if there is chance of severe food reaction causing risk to the patient.
- American Academy of Pediatrics no longer recommends avoiding the influenza and MMR vaccines in patients with severe systemic allergic reactions to egg.

COMMENTS

- Milk allergy usually resolves by age 5. Risk factors for persistence are early cutaneous manifestations following milk ingestion, development of other atopic conditions, and persistence of milk-specific high IgE titers. Soy milk is recommended for these children, keeping in mind that about 15% of these children can develop soy allergy.
- Egg allergy has been thought to resolve in 66% of children by 5 yr of age and in 75% of children by 7 yr of age. Trials have shown that oral immunotherapy can desensitize a high proportion of children with egg allergy and induce sustained unresponsiveness in a clinically significant subset.

TABLE 1 Food Processing Conditions That May Affect Allergenic Activity

Processing Stage	Nature of Processing	Impact of Processing on Allergens	Food-Level Evidence	Clinical Implications
Post-harvest treatments	Modified atmosphere for storage of fruit and vegetables	Expression of Bet v 1 homologs is upregulated during storage; levels are higher in fruit stored for 4-5 mo compared with fresh fruit. Expression of LTP allergens is downregulated during storage; levels are higher in fresh fruit and decrease during storage.	Apple	Individuals with birch pollen–related fruit allergies may tolerate freshly picked but not stored fruit. LTP-allergic individuals may experience reverse symptoms, although severity of LTP allergies may completely preclude consumption of problem fruit.
Primary processing	Removal of outer layers by physical or chemical peeling	Loss of allergens such as LTPs located in the outer layers.	Peach	Peeling fruits can make them safe for consumption by certain individuals with LTP allergies.
Secondary processing	Fruit purees and fresh juices	Labile Bet v 1 homologs are modified. Prolamin superfamily fruit LTPs retain a native-like structure.	Peach, apple	Individuals with Bet v 1–related fruit allergies usually can consume pureed fruit products. These foods can still trigger reactions in individuals with LTP fruit allergies.
	Preparation of pasteurized, UHT fruit juices and milk	Labile Bet v 1 homologs are modified. Prolamin superfamily fruit LTPs retain a native-like structure. Milk allergens retain much of their native structure.	Peach, apple, milk	Individuals with Bet v 1–related fruit allergies usually can consume UHT-processed fruit products. Processing is insufficient to make UHT juices safe for individuals with LTP fruit allergies. The allergenic potential of UHT milk resembles that of pasteurized and raw milk.
	Boiling	The prolamin superfamily LTPs and 2S albumin retain a native-like structure after boiling, although when seeds are boiled, much of the protein is lost into cooking water. Boiling alters the structure of milk, egg, and fish allergens. Boiling alters the structure of cupin allergens (7S and 11S seed storage proteins) and can render them insoluble.	Maize, wheat, peanut, lentil, fish, milk, egg	Boiling seeds (e.g., peanuts) and milk reduces their allergenicity but does not abolish it. For some foods (e.g., polenta), the extent of cooking affects the residual level of allergenic activity.
	Roasting and frying	Thermostable allergens, notably the prolamin superfamily 2S albumin allergens, retain their native structure and solubility after roasting and frying. Some cupin allergens (7S and 11S seed storage proteins) are altered by roasting and become insoluble. Maillard modification of allergens may take place under these processing conditions.	Peanut	The major peanut 2S albumin allergens retain their allergenic activity, explaining why roasted peanuts possess significant allergenic activity. Allergenic activity of the 7S and 11S globulins is retained to some extent after roasting. Maillard modifications may further contribute to the allergenic activity of roasted peanuts.
	Preparation of powdered ingredients, such as celery spice, skimmed milk, and pasteurized egg white powder	Major allergens retain their three-dimensional structure and activity in dry-processed goods. Maillard modifications take place under these processing conditions when residual sugars are present (e.g., lactose in skimmed milk powder).	Celery spice, milk	Powdered food ingredients have allergenic activity similar to unprocessed foods and can promote trigger reactions when included in recipes or through cross-contact in other foods (e.g., residual milk powder in foods otherwise free from milk).
	Deamidation	Acidic conditions are used to treat food ingredients (notably gluten) to improve their food functional properties through deamidation.	Gluten	Induces formation of novel IgE epitopes through glutamine deamidation, which results in individuals reacting to foods prepared with deamidated gluten ingredients who can otherwise safely consume wheat flour–containing foods.

Continued

TABLE 1 Food Processing Conditions That May Affect Allergenic Activity

Processing Stage	Nature of Processing	Impact of Processing on Allergens	Food-Level Evidence	Clinical Implications
	Hydrolyzed food ingredients	Enzymatic (usually microbial proteases) and chemical treatments are used to hydrolyze protein ingredients to change their functional properties. Ingredients may originate from soy, milk (e.g., caseinates, whey protein), gluten, and other sources.	Milk, egg, gluten	Hydrolysis reduces IgE reactivity but does not abolish it completely, which may in part result from the presence of residual intact protein. Evidence is largely limited to in vitro IgE binding studies and animal models with little direct in vivo evidence for allergic humans.
	Oil refining	Proteins are removed during the refining process, and residual protein levels in highly refined oils are very low.	Soybean, peanut	In the EU, highly refined soybean oils are considered safe for consumption by individuals with soy allergies. Highly refined peanut oils do not appear to cause adverse reactions in peanut-allergic individuals, but these oils do not have an EU labeling derogation.
Complex foods	Fining agents added to alcoholic beverages	Certain beverages contain residual levels of fining agents based on isinglass, fish gelatin, milk casein, egg albumin, or lysozyme. Fining agents and their residues in beverages usually are highly modified compared with the raw, unprocessed foods.	Beer, wine, and spirits	Individuals with allergies to fish triggered by collagen or egg can react to alcoholic beverages when they are used as fining agents, although this depends on the nature of the individual's allergy and whether fining agents are used in conjunction with other agents, such as bentonite. Reactions to fining agents are rare, and many individuals with egg, milk, or fish allergy can safely consume these beverages.
	Fermented foods	Lactic acid fermentations can cause proteins to unfold and precipitate or form gelled networks due to the reduced pH. Fermentative organisms secrete proteases that can hydrolyze proteins.	Milk, soybean	Although fermented milk and yogurt may retain some allergenic activity, other highly modified foods, such as soy sauce, may have substantially reduced allergenic activity and may not present a hazard to certain allergic patients.
	Baked foods	Food ingredients may be included that are raw or have already been processed (e.g., skimmed milk powder, pasteurized egg white). Complex interactions between different food ingredients coupled with further cooking modify allergens and result in their becoming part of the insoluble food matrix, but data are limited because of the poor solubility of allergens in physiologic buffers.	Milk	Evidence from oral food challenge studies indicates that baking reduces the allergenic activity of milk, and foods with baked milk may be given to children whose infantile cow's milk allergy is beginning to resolve.

EU, European Union; *LTP*, lipid transfer protein; *UHT*, ultrahigh temperature.

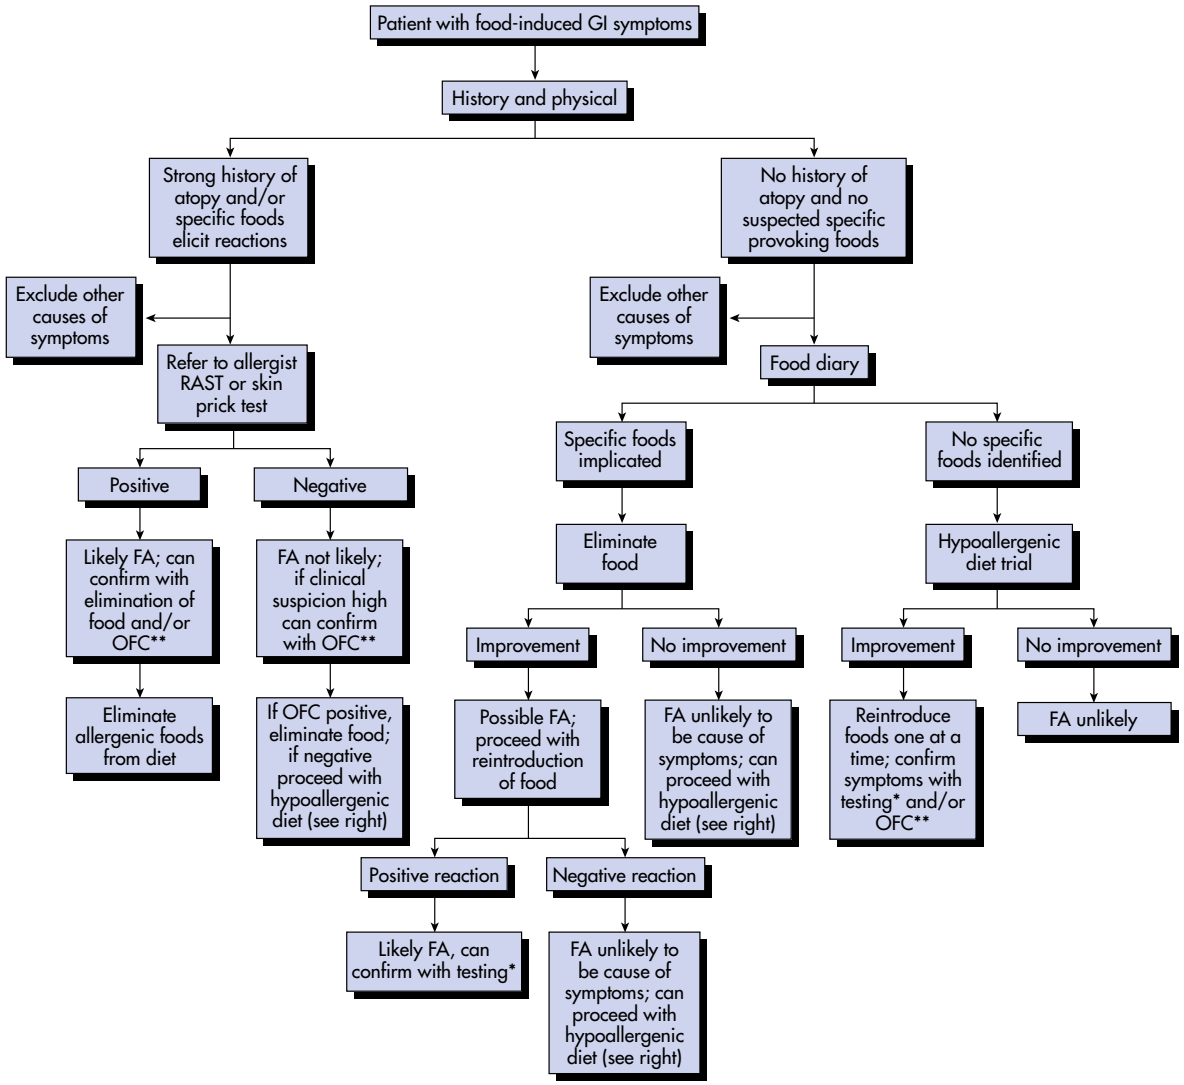

FIG. 1 Algorithm for the management of food allergy *Testing indicates skin-prick testing, radioallergosorbent tests *(RAST),* IgG_4 assay, and/or patch testing. Note that clinical symptoms must be associated with the food(s) that test positive before the food(s) should be eliminated from the diet. **Oral food challenge *(OFC)* involves reintroducing the food and observing for signs/symptoms of food allergy *(FA).* Treatment of food allergy involves elimination of the causative food(s) from the diet.

- Wheat allergy found to resolve by 5 yr of age and soybean allergy by 2 yr of age.

PREVENTION

- There is conflicting evidence regarding the protective effect of breastfeeding on food allergies.
- There is no evidence to suggest that exclusive breastfeeding for 6 mo or more is superior to exclusive breastfeeding for 4 to 6 mo in terms of developing food allergies.
- In high-risk infants who are not exclusively breastfed, there is limited evidence to suggest that feeding with hydrolyzed formula compared to cow's milk formula reduces allergies.
- Currently, there is no evidence to support the use of prebiotics and/or probiotics for the prevention of allergic diseases.
- No current evidence exists to support delaying the introduction of solid foods beyond 4 to 6 mo.
- The early introduction of peanuts significantly decreases the frequency of the development of peanut allergy among children at high risk for this allergy and modulated immune responses to peanuts.[2] Early peanut introduction (ages 4 to 11 months) lowers the risk of developing peanut allergy by 80% compared with peanut introduction after age 5 yr.
- In recent phase 3 trials of oral immunotherapy in children and adolescents who were highly allergic to peanut, treatment with AR101 resulted in higher doses of peanut protein that could be ingested without dose-limiting symptoms.

PATIENT & FAMILY EDUCATION

Information can be found on American Academy of Allergy, Asthma and Immunology (www.aaaai.org), the Food Allergy and Anaphylaxis Network (www.foodallergy.org), and the Anaphylaxis Campaign (www.anaphylaxis.org.uk).

REFERRAL

Patients may be referred to an allergy/immunology specialist when the diagnosis is uncertain or if avoidance measures are not successful.

BASIC INFORMATION

DEFINITION

Food poisoning is an illness caused by ingestion of food contaminated by bacteria and/or bacterial toxins. A foodborne disease outbreak is defined as two or more cases of a similar illness resulting from ingestion of a common food.

SYNONYMS

Enterotoxin-poisoning
Epidemic vomiting disease

ICD-10CM CODE
A05.9 Bacterial foodborne intoxication, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- CDC estimates that each yr one in six Americans will experience a foodborne illness.
- Approximately 800 foodborne disease outbreaks are reported in the U.S. each yr, accounting for approximately 15,000 illnesses, 800 hospitalizations, and 20 deaths. Outbreak-associated foodborne illnesses are only a small subset of the estimated 9.4 million foodborne illnesses that occur annually in the U.S.[1]
- Majority of identifiable causes are bacterial, although more than 250 known diseases can be transmitted through food.

PEAK INCIDENCE: Varies with specific organism

- Summer: *Staphylococcus aureus, Salmonella, Shigella* spp.
- Summer and fall: *Clostridium botulinum, Vibrio parahaemolyticus*
- Spring and fall: *Campylobacter jejuni*
- Winter: *Clostridium perfringens, Yersinia enterocolitica*

PREDOMINANT AGE: Varies with specific agent
NEONATAL INFECTION: Rare but severe with *Shigella* and *Salmonella* spp.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Any combination of GI symptoms and fever. Orthostatic pulse and blood pressure changes should be noted
- Specific organisms suspected on the basis of the incubation period and predominant symptoms (Table 2), although a great deal of overlap exists
  1. Short incubation period (1 to 6 hr): Involve the ingestion of preformed toxin; noninvasive.
     a. *S. aureus:* Nausea, profuse vomiting, and abdominal cramps common; diarrhea possible, but fever uncommon; usually resolves within 24 hr; foods implicated in outbreaks include meats, mayonnaise, and cream pastries.
     b. *B. cereus:* Two forms, a short incubation (emetic) form (characterized by vomiting and abdominal cramps in virtually all patients, diarrhea in one third of patients, fever uncommon) and a long incubation (diarrheal) form; illness usually mild, resolves within 12 hr; unrefrigerated rice most often implicated as vehicle. Other sources include gravy, meats, stews, vanilla, and sauces.
  2. Moderate incubation period (8 to 16 hr): Involves the in vivo production of toxin; noninvasive.
     a. *C. perfringens:* Severe crampy abdominal pain and watery diarrhea common; fever and vomiting unlikely; symptoms usually resolving within 24 hr; outbreaks invariably related to cooked meat or poultry that is allowed to cool without refrigeration; most cases in the fall and winter months. *C. perfringens* is the third most common cause of foodborne illness in the United States.
     b. *B. cereus:* Diarrheal (or long incubation) form most commonly beginning with diarrhea, abdominal cramps, and occasionally vomiting; fever uncommon; usually resolves within 24 hr; the responsible food is usually fried rice.
  3. Long incubation period (>16 hr): Some toxin-mediated, some invasive.
- Toxin-producing organisms include:
  1. *C. botulinum:* Should be considered when a diarrheal illness coincides with or precedes paralysis; severity of illness related to the quantity of toxin ingested; characteristic cranial nerve palsies progressing to a descending paralysis; fever usually absent; usually associated with home-canned foods.
  2. Enterotoxigenic *E. coli* (ETEC): Most common cause of travelers' diarrhea; after 1- to 2-day incubation period, abdominal cramps and copious diarrhea occur; vomiting and fever uncommon; usually resolves after 3 to 4 days; vehicle usually unbottled water or contaminated salad or ice.
  3. Enterohemorrhagic *E. coli* (EHEC): Can cause severe abdominal cramps and watery diarrhea, which may eventually become bloody; bacteria (strain O157:H7) are noninvasive; no fever; illness may be complicated by hemolytic-uremic syndrome; associated with contaminated beef (especially hamburger), unpasteurized milk or juice. Table 3 summarizes the various strains of diarrheagenic *E. coli.*
  4. *V. cholerae:* Varies from a mild, self-limited illness to life-threatening cholera; diarrhea, nausea, and vomiting, abdominal cramps, and muscle cramps; no fever; severe cases may progress to shock and death within hours of onset; survivors usually have resolution of symptoms in 1 wk; U.S. cases are either imported or result from ingestion of imported food.
- Invasive organisms include:
  1. *Salmonella:* Associated most often with nontyphoidal strains; incubation period generally 12 to 48 hr; nausea, vomiting, diarrhea, and abdominal cramps typical; fever possible; outbreaks of gastroenteritis related to contaminated poultry, meat, and dairy products.
  2. *Shigella:* Asymptomatic infection possible, but some with fever and watery diarrhea that may progress to bloody diarrhea and dysentery; with mild illness, usually self-limited, resolves in a few days; with severe illness, may develop complications; transmission usually from person to person but can occur via contaminated food or water.
  3. *C. jejuni:* The most common foodborne bacterial pathogen; incubation period is about 1 day, then a prodrome of fever, headache, and myalgias; intestinal phase marked by diarrhea associated with fever, malaise, and abdominal pain; diarrhea mild to profuse and bloody; usually resolves in about 7 days, but relapse is possible; associated with undercooked meats and poultry, unpasteurized dairy products, and drinking from freshwater streams.
  4. *Y. enterocolitica* and *Y. pseudotuberculosis:* Infrequent causes of enteritis

[1] Dewey-Mattia D et al: Surveillance for foodborne disease outbreaks–United States 2009-2015, *MMWR Surveill Summ* 67(10):1-11, 2018.

TABLE 1 Pathogenic Mechanisms in Bacterial Foodborne Disease

Preformed Toxin	Toxin Production in Vivo	Tissue Invasion	Toxin Production and/or Tissue Invasion
Staphylococcus aureus	*Clostridium perfringens*	*Campylobacter jejuni*	*Vibrio parahaemolyticus*
Bacillus cereus (short incubation)	*B. cereus* (long incubation)	*Salmonella*	*Yersinia enterocolitica*
Clostridium botulinum	*C. botulinum* (infant botulism)	*Shigella*	
	Enterotoxigenic *Escherichia coli*	Invasive *E. coli*	
	Vibrio cholerae 01 or 0139		
	V. cholerae non-01		
	Shiga toxin–producing *E. coli*		

From Mandell GL et al: *Principles and practice of infectious diseases,* ed 6, Philadelphia, 2005, Churchill Livingstone.

TABLE 2 Foodborne Disease Agents and Clinical Presentation

Usual Incubation Periods	Causative Agent	Clinical Illness			Epidemiologic and Laboratory Diagnosis
		Fever	Diarrhea	Vomiting	
5 min-6 h (usually <3 h)	Chemical or toxin	Rare	Occasional	Common	Demonstration of toxin or chemical from food or epidemiologic incrimination of food
1-6 h (usually <1 h)	*Staphylococcus aureus* enterotoxin	Rare	Occasional	Profuse	Isolation of organisms in food (>10^5/g)/vomitus/stool; detection of enterotoxin in food
	Bacillus cereus emetic toxin	Rare	Occasional	Profuse	Isolation of organisms in food (>10^5/g)/vomitus/stool
6-24 h	*Clostridium perfringens* enterotoxin	Rare	Typical	Occasional	Isolation of organisms or toxin from food (10^5/g) or stools of ill persons, epidemiologic incrimination of food; detection of enterotoxin in food
	B. cereus enterotoxin	Rare	Typical	Occasional	
12-72 h	*Clostridium botulinum*	Clinical sydrome compatible with botulism	Constipation more common		Isolation of organism or toxin from food (10^5/g) or stools; demonstration of toxin in serum or food
16-96 h	*Shigella*	Common	Typical, often bloody	Occasional	Isolation of organism from clinical specimens from two or more ill persons; isolation of organism from epidemiologically implicated food
	Nontyphoidal *Salmonella*	Common	Typical	Occasional	
	Enteroinvasive *E. coli* (EIEC)	Common	Typical, may be bloody	Occasional	
	Enteropathogenic *E. coli* (EPEC)	Occasional	Typical	Occasional	
	Enterotoxigenic *E. coli* (ETEC)	Rare	Typical	Rare	
	Vibrio parahaemolyticus; V. cholerae enterotoxin	Occasional	Typical	Occasional	
1-3 days	Caliciviruses (noroviruses) Rotavirus	Occasional	Typical	Common	Antigen detection (enzyme immunoassay) in stool; immune electron microscopy of stool; detection of viral RNA in stool or vomitus by PCR
1-10 days	*Yersinia*	Uncommon	Typical, severe abdominal pain	Uncommon	Isolation of organisms from food or clinical specimens of ill persons
2-10 days	*Campylobacter jejuni*	Common	Typical, often bloody	Uncommon	Isolation of organisms from food or clinical specimens of ill persons
1-11 days	*Cryptosporidium*	Occasional	Common	Occasional	Demonstration of oocysts in stool or in small bowel biopsy of ill persons; demonstration of organism in epidemiologically implicated food
	Cyclospora	Occasional	Common	Occasional	Demonstration of parasite in stool or in small bowel biopsy of ill persons; demonstration of organism in epidemiologically implicated food
	Giardia intestinalis	Occasional	Common	Occasional	Demonstration of parasite in stool or in small bowel biopsy of ill persons; demonstration of organism in epidemiologically implicated food
2 days-wks	*Bacillus anthracis*	Common	Typical	Frequent	Isolation of organism from blood or contaminated meat
1-7 days	*E. coli* O157:H7 and other Shiga toxin–producing *E.coli*	Uncommon	Typical	Frequent	Isolation of organism from food or stool or identification of toxin in stools of ill persons
3-60 days, usually 7-14	*Salmonella typhi*	Common	Diarrhea or constipation	Uncommon	Isolation of organisms from food or clinical specimens of ill persons
7-21 days	*Brucella* spp.	Common	Common	Rare	Isolation of organisms from blood or bone marrow culture of ill persons; fourfold increase in standard agglutination titer overall several wks or single titer 1:160 in person with compatible clinical syndrome
1-4 wk	*Giardia lamblia*	Rare	Common	Rare	Stool for ova and parasite examination enzyme immunoassay
2 days-8 wk	*Trichinella spiralis*	Common	Common	Common	Serology, muscle biopsy

PCR, Polymerase chain reaction; *RNA*, ribonucleic acid.
From Cherry JD et al: Feigin and Cherry's *Pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

in the United States; children affected more often than adults; fever, diarrhea, and abdominal pain lasting 1 to 3 wk; some with mesenteric adenitis that mimics acute appendicitis; contaminated food or water is usually responsible.

5. *V. parahaemolyticus:* In the United States, most outbreaks in coastal states or on cruise ships during the summer months; incubation period usually >1 day, followed by explosive watery diarrhea in the majority of cases; nausea, vomiting, abdominal cramps, and headache also common; fever less common; usually resolves by 1 wk; related to ingestion of seafood.
6. Enteroinvasive *E. coli* (EIEC): A rare cause of disease in the United States; high incidence of fever and bloody diarrhea; may resemble bacillary dysentery.

TABLE 3 Diarrheagenic *Escherichia coli*

Strains	Pathogenic Mechanisms	Persons Affected	Clinical Features
DAEC	Diffuse adherence to Hep-2 cells	Children in developing countries	Watery diarrhea (acute) and persistent diarrhea
EAEC	Aggregative adherence to Hep-2 cells	Children in developing countries	Watery diarrhea (acute) and persistent diarrhea
STEC O157:H7 Non-O157:H7 O104:H4*	Shiga toxins 1 and 2	Children and adults Persons who ingest contaminated food, especially hamburger (outbreaks)	Watery diarrhea Bloody diarrhea (classic)
EIEC	Epithelial cell invasion	Children and adults	Watery diarrhea Dysentery
EPEC Typical Atypical	Attaching and effacing Bundle-forming pilus, attachment and effacement lesions or atypical adherence pattern	Children	Watery diarrhea (acute) Persistent diarrhea
ETEC	Heat-labile and/or heat-stable toxin Adherence	Children in developing countries; travelers	Watery diarrhea

DAEC, Diffusely adhering *Escherichia coli*; *EAEC,* enteroaggregative *E. coli*; *EIEC,* enteroinvasive *E. coli*; *EPEC,* enteropathogenic *E. coli*; *ETEC,* enterotoxigenic *E. coli*; *STEC,* Shiga toxin–producing *E. coli.*
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

7. *V. vulnificus:* May cause serious, often fatal illness in persons with chronic liver disease; GI symptoms usually absent, but fever, chills, hypotension, and hemorrhagic skin lesions possible; patients with liver disease or at increased risk of developing liver disease should avoid eating raw oysters.

ETIOLOGY

- Table 1 describes pathogenic mechanisms in bacterial foodborne disease.
- Classically categorized as either inflammatory (invasive) or noninflammatory:
  1. *Noninflammatory: B. cereus, S. aureus, C. botulinum, C. perfringens, V. cholerae, enterotoxigenic E. coli (ETEC), and enterohemorrhagic E. coli (EHEC); toxin-producing organisms that are noninvasive; fecal leukocytes are not seen.*
  2. Inflammatory: *Campylobacter,* enteroinvasive *E. coli* (EIEC), *Salmonella, Shigella, V. parahaemolyticus,* and *Yersinia;* cause disease by invasion of intestinal tissue; fecal leukocytes are seen.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Gastroenteritis caused by viruses (Norwalk, Noro, or rotavirus), parasites *(Amoeba histolytica, Giardia lamblia),* or toxins (ciguatoxins, mushrooms, heavy metals).

LABORATORY TESTS

- Watchful waiting is often the most appropriate option and ancillary testing is usually not necessary.
- In severe or persistent cases stool test for fecal leukocytes may help narrow the differential diagnosis:
  1. Send stool for culture and for ova and parasites.
  2. Send stool for *C. difficile* toxin in patients with current or recent antibiotic use.
  3. Note: Some pathogens are not identified on routine stool culture; laboratory should be advised if *Yersinia, C. botulinum, Vibrio,* or enterohemorrhagic *E. coli* (O157:H7) are suspected.
  4. Finding *B. cereus, C. perfringens,* or *E. coli* in stool is of little value, because these may be part of the normal bowel flora.
  5. Stool cultures are positive in less than 40% of cases.
  6. Newer techniques such as polymerase chain reaction (PCR) testing provide a more rapid and reliable determination of specific pathogens.
- If botulism suspected, send food, serum, and stool for toxin assay.
- Blood cultures should be considered for all febrile patients.
- Consider toxic megacolon (identified on plain abdominal sonography).
- Consider sigmoidoscopy to obtain tissue and histology in hospitalized patients with bloody diarrhea.
- Consider lactoferrin measurement if an inflammatory etiology is suspected.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Adequate rehydration is the mainstay of therapy.

ACUTE GENERAL Rx

- Most cases of acute infectious diarrhea are viral and antibiotics are not indicated.
- Gastroenteritis caused by the following bacterial organisms requires no antimicrobial treatment: *B. cereus, S. aureus, C. perfringens, V. parahaemolyticus, Yersinia,* and enterohemorrhagic and enteroinvasive *E. coli.*
- The usual cause of travelers' diarrhea is enterotoxigenic *E. coli.* Although usually a self-limited illness, antibiotics can shorten the course in patients with fever or dysentery.
  1. Azithromycin 1000 mg in a single oral dose or
  2. SMX/TMP one DS tab bid for 3 days or
  3. Ciprofloxacin 500 mg PO bid for 3 days
- The mainstay of therapy for cholera is fluid replacement. Antibiotics should be given to decrease shedding and duration of illness.
  1. Doxycycline 300 mg in a single dose or 100 mg PO bid for 3 days
  2. SMX/TMP one DS tab bid for 3 days
- Treatment is not indicated for *Salmonella* gastroenteritis. Patients who are at high risk of developing bacteremia may be treated for 48 to 72 hr (see "Salmonellosis").
- Although shigellosis tends to be a self-limited illness, antibiotics shorten the course of illness and may limit transmission of the illness (see "Shigellosis").
- Those with moderate or severe *Campylobacter* diarrhea may benefit from treatment.
  1. Azithromycin 500 mg qd for 3 days or
  2. Erythromycin 500 mg PO qid for 5 days or
  3. Ciprofloxacin 500 mg PO bid for 5 days
- *V. vulnificus* sepsis should be treated with:
  1. Doxycycline 100 mg IV bid for 2 wk
  2. Ceftazidime 2 g IV q8h for 2 wk
- For suspected botulism, antitoxin should be administered early (see "Botulism").
- Table 4 summarizes antibiotic therapy for nonsevere infections with common bacterial enteropathogens in immunocompetent adults.

CHRONIC Rx

Patients with *Salmonella* infections may become carriers and may require treatment (see "Salmonellosis").

DISPOSITION

- Most infections are self-limited and do not require therapy.
- In immunocompromised host or patient with underlying disease, serious complications are possible.
- Postinfectious syndromes are important with some infections:
  1. Reiter syndrome: *Salmonella, Shigella, Campylobacter, Yersinia* spp.; more common in genetically susceptible host (HLA-B27+)
  2. Guillain-Barré syndrome: *Campylobacter* spp

TABLE 4 Antibiotic Therapy for Nonsevere Infections with Common Bacterial Enteropathogens in Immunocompetent Adults

Organism	Recommended Antibiotic(s)	Alternative Antibiotic(s)
***Shigella* Species**		
Shigella infection (non-*dysenteriae*; for *Shigella dysenteriae* type 1, see text)	Ciprofloxacin 500 mg twice daily (or levofloxacin 500 mg daily) × 3 days	Azithromycin 500 mg-1 g daily × 3-5 days TMP/SMX 160 mg/800 mg twice daily, if sensitive, × 3 days
***Salmonella* Species**		
Enterocolitis, uncomplicated	Not usually recommended (see text)	Can consider in areas of high fluoroquinolone quinolone resistance; Azithromycin 1 g daily × 5 days
Typhoid and enteric fevers*	Ciprofloxacin 500 mg twice daily (or ofloxacin 400 mg twice daily) × 7-14 days Ceftriaxone 2-3 g IV daily × 7-14 days	
***Campylobacter* Species**		
Campylobacter jejuni	Not usually required Ciprofloxacin 500 mg twice daily × 3 days	Azithromycin 500 mg-1 g × 3-5 days
Yersinia enterocolitica		
Enterocolitis, uncomplicated	Not usually required	An aminoglycoside (parenteral)Tetracycline 500 mg 4 times daily × 5 days TMP/SMX 160 mg/800 mg twice daily × 5 days Ciprofloxacin 500 mg twice daily × 5 days Doxycycline 100 mg twice daily × 5 days
Escherichia coli†		
Enterotoxigenic	Endemic disease; usually self-limited, supportive care (see text). Travelers' diarrhea: ciprofloxacin 500 mg twice daily × 3 days Rifaximin 200 mg 3 times daily × 3 days	Azithromycin 500 mg-1 g daily × 3-5 days TMP/SMX 160 mg/800 mg twice daily, if sensitive, × 3 days
Shiga toxin–producing	Unclear if antibiotics are effective; may be harmful	
***Vibrio* Species**		
Vibrio cholera	Doxycycline 300 mg × 1 dose	Ciprofloxacin 1 g × 1 dose Azithromycin 1 g × 1 dose Tetracycline 500 mg every 6 hours × 3 days
Vibrio parahaemolyticus	Usually not required; no controlled trials	As for *V. cholerae*

TMP/SMX, Trimethoprim/sulfamethoxazole.

NOTE: All antibiotics are administered orally unless otherwise indicated. Recommendations are given for treatment of mild/moderate infections only. Treatments for complicated infections or severely ill, bacteremic, or immunocompromised patients are not listed above and may differ from treatments for mild disease.

*For severe typhoid fever, consider the addition of glucocorticoids (dexamethasone 3 mg/kg × 1, then 1 mg/kg every 6 hours × 48 hours) to parenteral antimicrobial therapy. Antimicrobial sensitivity testing is required. Fluoroquinolones (e.g., ciprofloxacin) should not be used as empiric therapy in Asia or other areas with high fluoroquinolone resistance.

†Enteropathogenic, enteroaggregative, and diffusely enteroadherent *E. coli* are omitted from this table because these types are defined in research laboratories and are not diagnosed in routine clinical practice. Enteroinvasive *E. coli* presenting as inflammatory diarrhea should be treated empirically as for *Shigella* spp.

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

REFERRAL

If more than a mild illness

PEARLS & CONSIDERATIONS

COMMENTS

- Grossly underreported and undiagnosed
- All cases to be reported to the local health department
- Table 5 summarizes control and prevention measures of foodborne diseases

TABLE 5 Control and Prevention of Foodborne Diseases

General Recommendations for All Persons

- Thoroughly cook raw food from animal sources, such as beef, pork, poultry, fish, and eggs, to temperatures that eliminate most pathogens.*
- Wash raw fruits and vegetables before eating.
- Keep uncooked meats separate from fruits, vegetables, cooked foods, and ready-to-eat foods.
- Do not thaw meat, poultry, or fish on the counter (instead, thaw in a refrigerator, in cold water, or in a microwave oven).
- Wash hands before, during, and after preparing food and before eating food.
- Wash knives, other utensils, and cutting boards after handling uncooked foods.
- Keep refrigerators set to below 40° F and freezers set to 0° F or lower and verify with a thermometer.
- Refrigerate perishable foods within 2 hr (or within 1 hr if left out at temperatures >90°F).
- Read and follow all cooking and storage instructions on food product packaging. This is especially important for foods prepared in microwave ovens because these ovens heat foods unevenly. Even foods that may appear ready to eat may require thorough cooking.
- Persons with diarrhea or vomiting possibly caused by an infectious agent should not prepare foods for others.
- Keep all animals, including reptiles and amphibians, away from surfaces where foods or drinks are prepared.
- Do not drink unpasteurized (raw) milk or eat foods made from unpasteurized milk. (Exception: Hard cheeses made from raw milk that have been aged >60 days are generally safe to eat.)
- Do not eat home-canned foods that were not known to be adequately heat processed during canning.

Recommendations for Persons at High Risk, Such as Pregnant Women and People With Weakened Immune Systems, in Addition to the Recommendations Listed Above

Measures to Prevent a Variety of Bacterial Infections

- Do not eat uncooked sprouts.
- Do not drink prepackaged juice or juice-containing beverages that have not been processed to reduce or eliminate microbial contamination (e.g., by pasteurization).

Listeriosis Prevention Measures

- Do not eat soft cheeses, such as feta, Brie, and Camembert; blue-veined cheeses; and Mexican-style cheeses, such as queso blanco, queso fresco, and panela, unless the package has a label that clearly states that the cheese is made from pasteurized milk.
- Do not eat refrigerated pâtés or meat spreads. Canned or shelf-stable pâtés and meat spreads are safe to eat.
- Do not eat refrigerated smoked seafood unless it is contained in a cooked dish, such as a casserole. Refrigerated smoked seafood, such as salmon, trout, whitefish, cod, tuna, and mackerel, is most often labeled as "nova-style," "lox," "kippered," "smoked," or "jerky." The fish is found in the refrigerator section or sold at delicatessen counters of grocery stores and delicatessens. Canned or shelf-stable smoked seafood is safe to eat.
- Do not eat hot dogs, luncheon meats, or delicatessen meats unless they are reheated until steaming hot.
- Avoid getting fluid from hot dog packages on other foods, utensils, and food preparation surfaces, and wash hands after handling hot dogs, luncheon meats, and delicatessen meats.

Salmonellosis Prevention Measures

- Choose pasteurized eggs.

Vibriosis, Toxoplasmosis, and Norovirus Prevention Measures

- Do not eat raw or lightly steamed oysters, clams, or other raw shellfish (especially important for patients with liver disease).

More food safety information can be found at www.foodsafety.gov/keep/index.html.

*Poultry: 165°F (73.9°C); ground meats: 160°F (71.1°C); intact cuts of beef, pork, ham, veal, and lamb: 145°F (62.8°C) and allow to rest for at least 3 minutes before eating; fish and shellfish: 145°F (62.8°C); egg dishes: 160°F (71.1°C).

BASIC INFORMATION

DEFINITION

Friedreich ataxia is the most common hereditary neurodegenerative ataxic disorder. It results in degeneration of the dorsal root ganglia, posterior columns, spinocerebellar and corticospinal tracts, and large sensory peripheral neurons.

ICD-10CM CODE
G11.1 Early-onset cerebellar ataxia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Estimated at 1 in 30,000 Caucasians
PEAK INCIDENCE: 8 to 15 yr
PREVALENCE (IN U.S.): 2 to 4 per 100,000. Carrier rate 1:120 to 1:160; lower prevalence in people of Asian or African descent
PREDOMINANT SEX: Males and females affected equally
GENETICS: Autosomal recessive; 96% of affected patients are homozygous and 4% are compound heterozygous (two different mutations). Trinucleotide repeat expansion accounts for 94% to 98% of cases, whereas point mutations account for 2% to 6% of cases.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Onset of progressive appendicular and gait ataxia, with absent muscle stretch reflexes in the lower extremities
- With disease progression (within 5 yr): Dysarthria, distal loss of position and vibration sense, pyramidal leg weakness, areflexia in all four limbs, and extensor plantar responses
- Common findings: Progressive scoliosis, distal atrophy, pes cavus, and cardiomyopathy (symmetric concentric hypertrophic form in most cases)
- Insulin-requiring diabetes mellitus may occur in 10% of patients with glucose intolerance occurring in an additional 10% to 20%

ETIOLOGY

- Genetic: Frataxin gene is localized to the centromeric region of chromosome 9q13.
- Normal sequence has 6 to 27 repeats; abnormal sequence has 120 to 1700 GAA repeats.
- Frataxin deficiency leads to impaired mitochondrial iron homeostasis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Charcot-Marie-Tooth disease type 2
- Abetalipoproteinemia
- Severe vitamin E deficiency with malabsorption
- Early-onset cerebellar ataxia with retained reflexes
- Autosomal-dominant cerebellar ataxia (spinocerebellar ataxia)

WORKUP

- Specific gene testing for the expanded GAA trinucleotide repeat (only required test). Other tests, listed below, support the diagnosis but are not specific like genetic testing.
- Diagnostic criteria include electrophysiologic evidence for a generalized axonal sensory or sensorimotor neuropathy.
- ECG may show widespread T-wave inversion and evidence of left ventricular hypertrophy. ECG abnormalities are present in 65% of patients.
- Sural nerve biopsy shows loss of large myelinated fibers.

LABORATORY TESTS

- Genetic testing
- Electromyography or nerve conduction study
- ECG and echocardiogram
- Peripheral blood smear for acanthocytes
- Lipid profile
- 2-hour glucose tolerance test
- Vitamin E levels (if necessary)

IMAGING STUDIES

MRI of the spinal cord may demonstrate spinal cord atrophy with essentially normal cerebrum, brainstem, and cerebellum (Fig. E1).

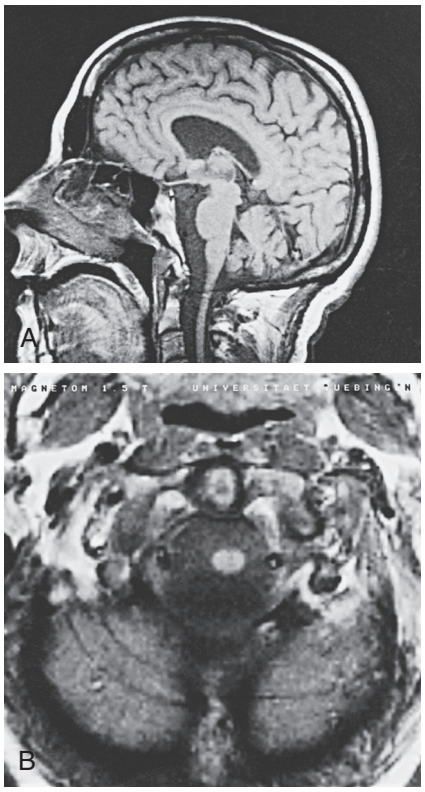

FIG. E1 T1 magnetic resonance image of the brain (midsagittal section) and spinal cord (axial slice at level of the dens) showing severe shrinkage of the cervical cord, but the cerebellum and brain stem are of normal size. (From Goetz CG: *Textbook of clinical neurology,* Philadelphia, 1999, Saunders.)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Surgical correction of scoliosis and foot deformities in selected patients
- Prosthetic devices as required (e.g., ankle-foot orthosis for footdrop)
- Physical therapy
- Communication devices for patients with severe dysarthria

ACUTE GENERAL Rx

None established.

- An antioxidant, idebenone (short-chain analogue of coenzyme Q10), administered orally at 5 to 20 mg/kg/day with or without vitamin E has demonstrated inconsistent effects on neurologic, cardiac, and psychosocial outcome measures in clinical trials.
- Further research with various antioxidants and iron chelators is ongoing. An open-label pilot study of antioxidants (coenzyme Q10, 400 mg/day, and vitamin E, 2100 U/day) in a small cohort demonstrated slowing in progression of generalized ataxia and kinetic dysfunction and significant improvement in cardiac function with unaltered deterioration in posture, gait, and hand dexterity.

CHRONIC Rx

Chronic management of congestive heart failure is required. Cardiac arrhythmias will warrant pacemaker implantation.

DISPOSITION

- Loss of ambulation typically occurs within 15 yr of symptom onset, and 95% are wheelchair bound by age 45 yr.
- Life expectancy is reduced, particularly if heart disease is present.

REFERRAL

- Neurologist for evaluation and diagnosis
- Genetic counseling (recommended if available)
- Cardiologist to manage cardiomyopathy and electrophysiologic abnormalities

PEARLS & CONSIDERATIONS

Friedreich ataxia should be considered in all preadolescent and adolescent children presenting with progressive ataxia. Early recognition of cardiac failure and arrhythmias and institution of appropriate therapy helps prolong survival.

Friedreich Ataxia (Patient Information)

AUTHORS: **Joseph S. Kass, MD, JD, FAAN,** and **Fariha Jamal, MD**

BASIC INFORMATION

DEFINITION

Frontotemporal dementia (FTD) is an umbrella term that encompasses three distinct syndromes: behavioral variant FTD (bvFTD), semantic dementia (SD), and progressive nonfluent aphasia (PNFA). All three syndromes are marked by frontal and/or temporal lobe atrophy; however, they manifest with different clinical presentations. The most common subtype is bvFTD, which is marked by changes in behavior and personality with disinhibition and the breaking of social norms. SD is characterized by a loss of word comprehension and meaning, and PNFA presents with agrammatic, nonfluent speech.

SYNONYMS

- FTD
- FTLD
- Frontotemporal lobar degeneration (FTLD) is the term used for the neuropathologic findings seen in the different FTD syndromes.
- Pick disease: This term was historically used to refer to FTD. However, it is now strictly a neuropathologic diagnosis for patients found to have Pick bodies at autopsy, as very few diagnoses of FTD are associated with these neuropathologic findings.

ICD-10CM CODES

G31.0 Frontotemporal dementia
G31.01 Pick disease
G31.09 Other frontotemporal dementia

EPIDEMIOLOGY & DEMOGRAPHICS

The current data on epidemiology of FTD are variable due to misdiagnosis and underreporting. The following data are estimations obtained through systematic reviews.

INCIDENCE: The estimated annual incidence is 2.7 to 4.1 per 100,000 persons.

PREVALENCE: The estimated point prevalence is 15 to 22 per 100,000 persons.

PREDOMINANT SEX AND AGE: There is a nearly equal distribution by sex, and the average age of presentation is 58 yr.

GENETICS: Approximately 40% of FTD cases have a positive family history, and several genes (Table 1) have been associated with the development of familial FTD. The most common are mutations in *C9ORF72, MAPT,* and *GRN* (Table 2).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The early stage of bvFTD is characterized by changes in behavior and personality. Patients display a lack of insight into these changes, and family members may initially think they are suffering a midlife crisis or a new-onset psychiatric disorder. Therefore, careful history-taking is required.
- Behavioral changes include disinhibition, impulsivity, distractibility, violation of social norms (such as offensive, insensitive, or inappropriate sexual remarks; inappropriate behaviors; inappropriately explicit or personal conversations; or encroachment on the personal space of others), as well as increased irritability and impulsive criminal behavior (such as shoplifting or violating traffic laws).
- Patients also display decreased ability to empathize with others, insensitivity to the needs and emotions of their loved ones, and distance/detachment in their personal relationships.
- Apathy and inertia are also common symptoms, with possible development of immobility as the disorder progresses.
- Other associated symptoms that may develop are changes in language and speech (verbal aspontaneity, stereotyped phrases, mutism in late stages), repetitive motor movements, or hyperphagia.
- Physical exam findings for bvFTD can include upper and/or lower motor neuron signs, dysarthria, dysphagia, and pseudobulbar affect. Some patients meet criteria for both FTD and amyotrophic lateral sclerosis.
- Although behavioral changes can also occur in the other FTD syndromes SD and PNFA, these two primarily have language deficits that precede the behavioral changes.
  1. SD is characterized by a gradual loss of the knowledge of words, objects, and concepts, with preservation of speech fluency and syntax.
  2. PNFA is characterized by effortful, nonfluent speech, word-finding difficulties, and agrammatism, with preservation of single-word comprehension.

DIAGNOSIS

Diagnosis of bvFTD is primarily clinical, with neuroimaging and pathology/genetics required for further confirmation. In 2011, the International Behavioral Variant FTD Consortium (FTDC) developed revised criteria for the diagnosis of bvFTD (Table 3).

- In summary, six core symptoms that can be seen in bvFTD were identified. The presence of any three is sufficient to diagnose *possible* bvFTD.
- Diagnosis of *probable* bvFTD requires meeting the following three conditions: (1) patient has diagnosed possible bvFTD, (2) significant functional decline, and (3) frontal and/or anterior temporal atrophy/hypoperfusion seen on imaging.
- Diagnosis of *definitive* bvFTD can be made only when the patient has possible or probable bvFTD, plus either (1) pathologic evidence of FTLD on biopsy or postmortem, or (2) presence of a known causal genetic mutation.

DIFFERENTIAL DIAGNOSIS

- Other neurodegenerative disorders, including Alzheimer disease (AD), idiopathic Parkinson disease, dementia with Lewy bodies, corticobasal syndrome, progressive supranuclear palsy, and chronic traumatic encephalopathy

TABLE 1 Clinical, Genetic, and Pathologic Correlations in Frontotemporal Lobar Degeneration

TABLE 3 International Consensus Criteria for Behavioral Variant FTD

Must be present for any FTD clinical syndrome:
- Shows progressive deterioration of behavior and/or cognition by observation or history

Possible bvFTD
- Three of the features (A-F) must be present; symptoms should occur repeatedly, not just as a single instance:
  - A. Early (3 yr) behavioral disinhibition
  - B. Early (3 yr) apathy or inertia
  - C. Early (3 yr) loss of sympathy or empathy
  - D. Early (3 yr) perseverative, stereotyped, or compulsive/ritualistic behavior
  - E. Hyperorality and dietary changes
  - F. Neuropsychological profile: executive function deficits with relative sparing of memory and visuospatial functions

Probable bvFTD
- All the following criteria must be present to meet diagnosis:
  - A. Meets criteria for possible bvFTD
  - B. Significant functional decline
  - C. Imaging results consistent with bvFTD (frontal and/or anterior temporal atrophy on CT or MRI or frontal hypoperfusion or hypometabolism on SPECT or PET)

Definite bvFTD
- Criteria A and either B or C must be present to meet diagnosis:
  - A. Meets criteria for possible or probable bvFTD
  - B. Histopathological evidence of FTLD on biopsy at post mortem
  - C. Presence of a known pathogenic mutation

Exclusion criteria for bvFTD
- Criteria A and B must both be answered negatively; criterion C can be positive for possible bvFTD but must be negative for probable bvFTD:
  - A. Pattern of deficits is better accounted for by other non-degenerative nervous system or medical disorders
  - B. Behavioral disturbance is better accounted for by a psychiatric diagnosis
  - C. Biomarkers strongly indicative of Alzheimer disease or other neurodegenerative process

Additional features
- Presence of motor neuron findings suggestive of motor neuron disease
- Motor symptoms and signs similar to corticobasal degeneration and progressive supranuclear palsy
- Impaired word and object knowledge
- Motor speech deficits
- Substantial grammatical deficits

bvFTD, Behavioral variant frontotemporal dementia; *FTD,* frontotemporal dementia; *FTLD,* frontotemporal lobar degeneration; *SPECT,* single-photon emission computed tomography.

- Psychiatric disorders (bipolar disorder, schizophrenia, obsessive-compulsive disorder, depression, personality disorders)
- Metabolic disturbances or nutritional deficiencies (hypothyroidism, B_{12} deficiency)
- Substance abuse/toxicities (ethanol, drugs of abuse, heavy metal poisoning)
- Infections (meningitis, HIV-associated dementia, neurosyphilis)
- Cerebrovascular disease (stroke, vascular dementia, lacunar infarctions)
- CNS tumors

WORKUP

- Careful history-taking with specific attention paid to initial symptoms, time course, progression of symptoms, family history, psychiatric history, and other medical history
- Comprehensive neurologic physical exam to help rule out other CNS etiologies
- Use of the International Behavioral Variant FTD Criteria for diagnosis (Table 3).
- Genetic testing for causal mutations of FTD *(C9ORF72, MAPT,* and *GRN).*
- Medication review (especially drugs that may alter mental status, such as anticholinergics, opiates, benzodiazepines, barbiturates, and neuroleptics)
- Neuropsychological tests of executive function, memory, and social cognition to rule out other neurodegenerative disorders
- Psychiatric evaluation to rule out psychiatric disorders

LABORATORY TESTS

- CBC, serum electrolytes, glucose, BUN/creatinine, liver function tests
- Cerebrospinal fluid (CSF) analysis for infection and measurement of CSF tau and amyloid (which can help differentiate between FTD and AD)
- Vitamin B_{12}, thyroid function tests, HIV, and syphilis screening
- Urine toxicity screen
- In vivo histopathology:
  1. Almost all cases of FTLD have one of the following protein inclusions found on pathologic examination: TAR DNA-binding protein with molecular weight 43 kDa (TDP-43), microtubule-associated protein tau (MAPT), or fused-in-sarcoma protein (FUS). If feasible and as medical technology advances, in vivo histopathologic testing can confirm the diagnosis.

IMAGING STUDIES

- In general, structural MRI and CT will show gray matter atrophy in the frontal and/or temporal lobes, anterior cingulate cortex, and insula with variation in distribution between the different FTD subtypes.
  1. Patients with bvFTD specifically will usually show atrophy in the orbitofrontal, anterior cingulate, anterior insular, and anterior temporal cortices.
  2. SD is associated with atrophy in the temporal poles, and PNFA with atrophy in the left perisylvian region.
- A normal MRI scan does not exclude FTD, however, because changes may not be seen in early stages of the disorder. In these cases, PET or SPECT can be used to visualize areas of hypoperfusion/hypometabolism.

Rx TREATMENT

- No disease-modifying drugs currently exist for the treatment of FTD. With advances in the understanding of FTD pathophysiology and genetics, however, new therapies such as antisense oligonucleotides and tau-specific antibodies are being investigated for their efficacy in treating or altering the progression of the syndrome and may see eventual clinical application.
- Current management of FTD is aimed at management of behavioral symptoms through both pharmacologic and nonpharmacologic means.

NONPHARMACOLOGIC THERAPY

- Due to the impulsivity and the risk for injury seen in bvFTD, discussions with family members about driving, the patient's access to finances, and safety of the physical environment should be conducted early in management.
- For patients with motor symptoms, regular exercise and physical therapy are helpful.
- Speech therapy is helpful for patients with language deficits.
- Diet counseling can aid in prevention of weight gain in patients with hyperphagia.

ACUTE GENERAL Rx

None

CHRONIC Rx

- There are conflicting reports of the efficacy of several medications in the symptomatic treatment of FTD. These include selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors, and antipsychotics.
- SSRIs have the most consensus on their benefit in the management of FTD. They have been shown to help decrease the severity of disinhibition, impulsivity, eating disorders, and repetitive behaviors.
- The use of antipsychotics is controversial, but they are sometimes given to control symptoms of aggression, agitation, and psychosis. However, patients with FTD are also at an increased risk for extrapyramidal side effects due to poorly functioning dopaminergic pathways, and thus are usually used only when SSRIs are not successful.

DISPOSITION

- Patients with FTD benefit from having the social support and specialized care offered in dementia-focused care homes and skilled nursing facilities.
- The range and severity of behaviors seen in FTD can put great burden on family and friends. Education, counseling, and connection with social support or referral to a dementia-focused care home can help reduce caregiver stress.

REFERRAL

Patients who have severe or complex presentations should be referred to a neurologist with expertise in dementia or neurodegenerative disorders.

PEARLS & CONSIDERATIONS

FTD is a complex neurologic disorder with a wide variety of presenting symptoms. The most common syndrome seen is bvFTD; therefore, patients with gradual-onset changes in personality, disinhibition, and increased impulsivity should be investigated for FTD. Therapy is aimed at management of the behavioral symptoms, most commonly through the use of SSRIs. Social support and dementia-specific care facilities are helpful for both patients and family members.

BASIC INFORMATION

DEFINITION

Frostbite represents tissue injury (or death) from freezing and vasoconstriction induced by severe environmental cold exposure.

SYNONYM

Cold-induced tissue injury

ICD-10CM CODES

T35.0	Superficial frostbite involving multiple body regions
T34	Frostbite with tissue necrosis
T345	Frostbite with tissue necrosis of wrist and hand
T34.8	Frostbite with tissue necrosis of ankle and foot
T34.9	Frostbite with tissue necrosis of other and unspecified sites
T35.4	Superficial frostbite involving multiple body regions
T33.9	Superficial frostbite of unspecified sites, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

- Environmental factors include windchill factor, temperature, duration of exposure, altitude, and degree of wetness. Hands and feet account for >90% of injuries; nose, cheeks, ears, and male genitalia are also more susceptible.
- Host factors include psychiatric illness and neuroleptic and sedative drugs (especially alcohol, which, in addition to impairing judgment, inhibits shivering and causes cutaneous vasodilation). Other risk factors include immobility, previous frostbite, malnutrition, tobacco use, peripheral neuropathy, peripheral vascular disease, diabetes, exhaustion, and constricting clothing and footwear.
- Patients at the extremes of age are at greatest risk, but frostbite is more common in adults between 30 and 49 yrs of age with a strong male predominance (10:1)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Frostbite may be classified into four degrees of injury severity or, more practically, into *superficial* (corresponding to first and second degree) and *deep* (corresponding to third and fourth degree) groups. In both cases, the degree of frostbite can only be accurately determined after rewarming as initially most frostbite injuries appear similar.
- *Superficial* frostbite involves the skin and subcutaneous tissue. The frozen part is waxy, white (or mottled), and firm but soft and resilient below the surface when gently depressed. After rewarming, there is an initial hyperemia that may be followed by swelling and formation of superficial blisters with clear or milky fluid within 6 to 24 hr. There is no ultimate tissue loss.
- *Deep* frostbite extends into the dermis and may involve muscles, nerves, tendons, or bones. The skin may be hard or wooden, without tissue resilience. Nonblanching cyanosis, hemorrhagic blisters, tissue necrosis (Fig. E1), and gangrene may develop. Affected tissue has a poor prognosis and debridement or amputation is generally required.
- Patients initially feel numbness, prickling, and itching. More severe injury can produce paresthesias and stiffness, with burning or throbbing pain upon thawing.

PATHOPHYSIOLOGY

Two phases of tissue injury:

1. The actual freezing of the tissues, during which cellular damage is caused by the formation of extracellular ice crystals, which cause osmotic shifts, cellular dehydration, cell membrane lysis, and cell death.
2. The reperfusion injury, during which the thawing of damaged endothelial cells releases a cascade of inflammatory mediators (e.g., prostaglandin F, thromboxane A2, bradykinins, histamine), resulting in capillary compression, vascular stasis, progressive ischemic injury, and thrombus formation. These conditions ultimately lead to the destruction of the microcirculation and to cell death.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Frostnip: A superficial nonfreezing cold injury associated with intense vasoconstriction and characterized by frost forming on the surface of the skin. Transient numbness, tingling, and pallor resolve quickly with warming
- Pernio (chilblains): Self-limited, cold-induced vasculitis associated with purple plaques or nodules, often affecting dorsum of hands and feet; seen with prolonged cold exposure to above-freezing temperatures
- Cold immersion (trench foot): Caused by ischemic injury resulting from sustained, severe vasoconstriction in appendages exposed to wet cold at temperatures above freezing

WORKUP

- Laboratory workup is not indicated unless the patient has systemic hypothermia.
- Early presentation (<24 hr from thawing): If there is deep frostbite with potential significant morbidity, perfusion evaluation with angiography (or Tc-99m or MRA) should be done emergently in anticipation of potential thrombolysis treatment.
- Late presentation (>24 hr from thawing): Noninvasive imaging with MRA or multiphase bone scintigraphy (ideally with SPECT/CT) can be used to predict the likely levels of tissue viability for future reconstruction after amputation.

TREATMENT (3 PHASES)

1. FIELD MANAGEMENT

- Prioritize treatment of hypothermia (core body temperature <35° C; 95° F) with systemic and adjunctive rewarming measures if available (e.g., warmed, humidified oxygen, heated IV saline [45° C; 113° F], and warming blankets) before thawing frostbitten extremities.
  1. Shelter patient out of wind and give warm fluids.
- Remove constricting or wet clothing and jewelry from affected digits.
  1. Place cold extremity in a companion's axilla or groin for 10 min, then replace dry gloves/boots.
- Insulate, splint, and elevate affected areas if practical to do so.
  1. Never rub or massage the affected area. Avoid dry heat (e.g., fires and heaters).
- Avoid thawing if there is any risk of refreezing and if possible avoid ambulation on thawed lower extremities (unless only distal toes affected).
- Box 1 describes the Alaska State Guidelines for prehospital treatment of frostbite.

2. REWARMING

- Rapid rewarming (with warm water) limits the freezing injury and yields better outcomes than slow rewarming (e.g., moving to a warmer location).
- Rapid rewarming is achieved by immersing the affected area in a circulating warm water bath with or without a mild antibacterial agent (e.g., chlorhexidine or povidone-iodine) maintained at 37° to 39° C for at least 15 to 30 min up to 1 hour, until all tissues are thoroughly rewarmed and pliable with a red-purple color. Active motion during rewarming is advisable; massage is not.
- Administer analgesics during rewarming (ibuprofen and possibly narcotics).

3. POST-THAW TREATMENT

- Tetanus prophylaxis and topical antibiotics if potentially contaminated skin wound.
- Consider systemic antibiotics for patients with significant trauma or signs of infection.
- Debride broken clear vesicles and avoid disrupting intact blisters (especially hemorrhagic ones) unless they interfere with mobility.
- Topical aloe vera (a potent anti-prostaglandin agent) q6h and ibuprofen (a thromboxane inhibitor) 400 to 600 mg bid to tid (or daily aspirin) can be given until wounds are healed or surgery occurs.
- Thrombolytic therapy: May consider if <24 hr from thawing in a patient with severe frostbite and poor prognostic indicators (e.g., cool skin after rewarming, numb, dusky or blue digits, hemorrhagic blisters). First, evaluate perfusion with angiography (or possibly MRA)

BOX 1 Alaska State Guidelines for Prehospital Treatment of Frostbite

First Responder/Emergency Medical Technician—I, II, III/Paramedic/Small Bush Clinic
Evaluation and Treatment

A. Anticipate, assess, and treat the patient for hypothermia, if present.
B. Assess the frostbitten area carefully because the loss of sensation may cause the patient to be unaware of soft tissue injuries in that area.
C. Obtain a complete set of vital signs and the patient's temperature.
D. Remove jewelry and clothing, if present, from the affected area.
E. Obtain a patient history, including the date of the patient's last tetanus immunization.
F. If there is frostbite distal to a fracture, attempt to align the limb unless there is resistance. Splint the fracture in a manner that does not compromise distal circulation.
G. Determine whether rewarming the frostbitten tissue can be accomplished in a medical facility. If it can, transport the patient while protecting the tissue from further injury from cold or impacts.
H. If the decision is made to rewarm frostbitten tissue in the field, you should prepare a warm water bath in a container large enough to accommodate the frostbitten tissues without them touching the sides or bottom of the container. The temperature of the water bath should be 99° to 102° F (37° to 39° C).
   1. Generally, patients with frostbite do not require opiates for pain relief; they occasionally need non-opiate pain medication or anxiolytics. If possible, consult a physician regarding the administration of oral analgesics, such as acetaminophen, ibuprofen or aspirin. Aspirin or ibuprofen may help improve outcomes by blocking the arachidonic acid pathway.
   2. Immersion injury or frostbite with other associated injuries may produce significant edema and high pain levels. These patients may need opiate pain medications for initial treatment. In this case, advanced life support personnel should administer morphine or other analgesics in accordance with physician-signed standing orders or online medical control.
I. A source of additional warm water must be available.
J. Water should be maintained at approximately at 99° to 102° F (37° to 39° C) and gently circulated around the frostbitten tissue until the distal tip of the frostbitten part becomes flushed.
K. Pain after rewarming usually indicates that viable tissue has been successfully rewarmed.
L. After rewarming, let the frostbitten tissues dry in the warm air. Do **not** towel dry.
M. After thawing, tissues that were deeply frostbitten may develop blisters or appear cyanotic. Blisters should not be broken and must be protected from injury.
N. Pad between affected digits and bandage affected tissues loosely with a soft, sterile dressing. Avoid putting undue pressure on the affected parts.
O. Rewarmed extremities should be kept at a level above the heart, if possible.
P. Protect the rewarmed area from refreezing and other trauma during transport. A frame around the frostbitten area should be constructed to prevent blankets from pressing directly on the injured area.
Q. Do not allow an individual who has frostbitten feet to walk except when the life of the patient or rescuer is in danger. Once frostbitten feet are rewarmed, the patient becomes nonambulatory.

to assess for arterial compromise. Next, administer intraarterial (or intravenous) tPA if perfusion defects are demonstrated and there is no contraindication to thrombolysis. Tissue salvage rate appears to correlate with elapsed time to treatment from time of rewarming and best outcomes seen within the first 12 hours. Although the use of early thrombolytic therapy appears to limit reperfusion injury and reduce subsequent digit amputation significantly, high-quality studies are lacking, and this treatment is not yet U.S. FDA-approved.

- Some protocols include heparin or prostacyclin in addition to tPA to prevent recurrent thrombosis.
- Vasodilator therapy: Various vasodilators (NTG, pentoxifylline, phenoxybenzamine, nifedipine, reserpine, and buflomedil) have been tried, with the best evidence favoring prostacyclin (or iloprost, an injectable available in Europe that has vasodilatory, fibrinolytic-enhancing, and antiplatelet activity). If iloprost is available, at least one study has shown superior efficacy to tPA, and it is easier to administer, has a better safety profile, has fewer contraindications, and can be managed on a general ward.
- Daily dressing changes with dry, sterile, noncompressive, and nonadherent dressings. Splint and elevate hands and feet to reduce edema and separate digits with cotton gauze. Avoid any abrasion to limit risk of infection.
- Whirlpool hydrotherapy: 1 to 2 times per day for 30 min with warm water (37° to 39° C), with or without an antiseptic solution if severe edema is present, until there is a clear demarcation of necrotic tissues or evidence of tissue healing.
- Gentle, progressive physical therapy after edema resolves.
- Keep site warm, and avoid all vasoconstrictors, including nicotine.
- Adjunctive treatments including dextran, warfarin, sympathectomy, and hyperbaric oxygen are of potential but unproven benefit.

DISPOSITION

A majority of patients have long-term residual symptoms, including cold hypersensitivity, neuropathic pain, sensory deficits, hyperhidrosis, secondary Raynaud disease, localized osteoporosis, edema, hair or nail deformities, and (rarely) arthritis. Treatment with tricyclics, gabapentin, calcium channel blockers, and careful protection from further cold exposure may be helpful.

REFERRAL

- Hospitalize for hypothermia or deep frostbite; a burn unit is best.
- Surgical decisions regarding amputation should be deferred until demarcation of viable tissue is clear. Traditionally, this can take 6 to 12 wk by clinical examination. Triple phase Tc-99m bone scan with SPECT/CT in the days after injury can be used to predict level of amputation accurately. Early surgical intervention is indicated if refractory pain, sepsis, or gangrene occurs.

Functional Gallbladder Disorder

BASIC INFORMATION

DEFINITION

Biliary pain caused by gallbladder dysmotility in the absence of gallstones, sludge, or microlithiasis. It is a diagnosis of exclusion with no evidence of structural disease seen with normal hepatobiliary and pancreatic laboratory and diagnostic imaging modalities.

SYNONYMS

Biliary dyskinesia
Gallbladder dyskinesia
Gallbladder spasm
Acalculous biliary disease
Chronic acalculous cholecystitis
Chronic acalculous
Gallbladder dysfunction
Cystic duct syndrome

ICD-10CM CODE
K82.9 Disease of gallbladder, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Biliary dyspepsia has an incidence rate of 1% to 6%.
PREVALENCE: Ten percent to 45% of total population report dyspepsia.
PREDOMINANT SEX AND AGE: There is a 3:1 female-to-male predominance.
RISK FACTORS: There is no consistent relationship to meals or fatty meal intake.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

These patients present with typical biliary pain that fulfills the Rome III criteria:

- Patients present with sporadic epigastric or right upper quadrant pain lasting for 30 min but less than 6 hours.
- Episodes are recurrent and occur in sporadic intervals (but not daily).
- The pain is not relieved by bowel movements.
- The pain is not relieved by postural movements.
- The pain is not relieved by antacids.
- The pain builds up to a steady level.
- The pain is severe enough it impedes daily activities and may even require an emergency department visit.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary gallbladder disorders: Gallstones, cholecystitis
- Pancreatobiliary disorders: Cholelithiasis, choledocholithiasis, pancreatitis, pancreatic neoplasm
- Gastrointestinal disorders: Gastroesophageal reflux disorder, peptic ulcer disease, inflammatory bowel disease, irritable bowel syndrome, gastric or esophageal neoplasm
- Metabolic disorders: Obesity, diabetes mellitus
- Cholecystokinin deficiency: Celiac disease

WORKUP

This is a diagnosis of exclusion in a patient with biliary pain. Patients will have normal blood test results and hepatobiliary and pancreatic enzymes, including aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), bilirubin, amylase, and lipase. Imaging, including abdominal ultrasound, is essentially normal without evidence of gallstone or gallbladder sludge pathology.

LABORATORY TESTS

Laboratory tests, including serum AST, ALT, ALP, bilirubin, gamma-glutamyl transferase, amylase, and lipase, are within normal limits.

IMAGING STUDIES

- To exclude gallstone pathology, a transabdominal ultrasound is initial choice for imaging. Transabdominal ultrasound is capable of detecting gallstones up to 3 to 5 mm in size. Patients should fast for at least 8 hours before ultrasound to optimize visualization of the gallbladder.
- If gallstones or gallbladder are not found on ultrasound but still suspected, endoscopic ultrasound (EUS) may be used to detect microlithiasis or gallstones smaller than 3 mm.
- Assessing gallbladder emptying through cholecystokinin (CCK)–stimulated cholescintigraphy is essential in the diagnosis. CCK-stimulated cholescintigraphy allows for the calculation of gallbladder ejection fraction (GBEF). Normal GBEF is >38%. Patients with a GBEF <35% to 40% with reproducible pain on CCK stimulation is suggestive of functional gallbladder disorder.

TREATMENT

In patients with appropriate evaluation for suspected functional gallbladder disorder, surgical management with cholecystectomy is the preferred method of treatment.

NONPHARMACOLOGIC THERAPY

Surgical cholecystectomy is the preferred method of treatment. Studies have shown symptomatic relief in up to 98% of patients postcholecystectomy.

ACUTE GENERAL Rx

- Initial management should include adequate analgesic control for abdominal pain.
- Opioid analgesics should be avoided because they may exacerbate symptoms involved in a hypofunctioning gallbladder.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Turmeric (Curcuma) has been known to alleviate biliary dyspepsia by stimulating gallbladder contractions.

DISPOSITION

Patients with functional gallbladder disorder are often misdiagnosed. These patients require appropriate evaluation to exclude other hepatobiliary etiology. After they are properly diagnosed, these patients have a favorable prognosis after surgical intervention.

REFERRAL

- Gastroenterology consultation may be considered to rule out microlithiasis via EUS.
- Surgical consultation should be considered for possible cholecystectomy in select patients.

PEARLS & CONSIDERATIONS

COMMENTS

Functional gallbladder disorder is a diagnosis of exclusion. It is essential that other hepatobiliary pathology be ruled out first. CCK-stimulation scintigraphy showing a reduced GBEF without any other pathology is suggestive of this disorder. Patients fare well with surgical intervention.

BASIC INFORMATION

DEFINITION

Galactorrhea can be defined as inappropriate lactation (in the absence of pregnancy or postpartum state) as a result of nonphysiologic augmentation of prolactin release.

ICD-10CM CODES

N64.3	Galactorrhea not associated with childbirth
O92.6	Galactorrhea in pregnancy

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Milky discharge from nipples (Fig. E1), usually occurring bilaterally
- Evidence of chest wall irritation from ill-fitting clothing, herpes zoster, or atopic dermatitis may be present
- Visual field defects (bitemporal hemianopsia) may be present with prolactinomas, particularly if large, such as macroadenomas
- Headaches may also occur in cases of large pituitary adenomas
- Evidence of acromegaly, Cushing syndrome, or hypothyroidism when galactorrhea is caused by these disorders

ETIOLOGY

- Medications (phenothiazines, metoclopramide, selective serotonin reuptake inhibitors, anxiolytics, buspirone, risperidone, atenolol, valproic acid, conjugated estrogen and medroxyprogesterone, methyldopa, verapamil, H_2 receptor blockers [cimetidine], octreotide, danazol, tricyclic antidepressants, isoniazid, amphetamine, reserpine, opiates, sumatriptan, rimantadine, oral contraceptive formulations): After infancy, galactorrhea is often medication induced
- Pituitary tumors (prolactinomas, craniopharyngiomas)
- Hypothyroidism (diminished feedback inhibition increases thyroid-releasing hormone [TRH], which increases prolactin)
- Breast stimulation: Prolonged suckling or during sexual intercourse
- Chest wall irritation from ill-fitting clothing, herpes zoster, atopic dermatitis, burns
- Breast surgery
- Chronic renal failure (decreased prolactin clearance)
- Cushing syndrome
- Herbs (e.g., fennel, red clover, anise, red raspberry, marshmallow)
- Cocaine
- Cannabis
- Spinal cord surgery or injury, or tumors
- Severe gastroesophageal reflux disease, esophagitis (stimulation of thoracic nerves by the cervical and thoracic ganglia)
- Neonatal ("witch's milk" produced by 2% to 5% of neonates because of precipitous drop in maternal estrogen and progesterone postdelivery)
- Cancer: Lymphomas, Hodgkin disease, bronchogenic carcinoma, renal adenocarcinomas
- Sarcoidosis and other infiltrative disorders
- Tuberculosis affecting pituitary gland
- Pituitary stalk resection
- Multiple sclerosis
- Empty sella syndrome
- Acromegaly
- Increased stress, including major trauma
- Exercise
- Idiopathic, diagnosis of exclusion

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Intraductal papilloma
- Breast cancer
- Paget disease of breast
- Breast abscess

WORKUP

- Complete history focusing on menstrual irregularity, infertility, previous pregnancies, duration of galactorrhea, medications, visual complaints, fatigue. Age of onset is also significant (e.g., prolactinoma most common between ages 20 and 35 yr; neonatal galactorrhea is usually secondary to transplacental transfer of maternal estrogen)
- Physical examination: Height, weight, vital signs. Evidence of hirsutism, acne, obesity, visual field defects, goiter, neurologic deficits
- Breast examination for presence of nodules, evaluation of discharge (milky versus serosanguineous versus purulent). Inspection of chest wall
- Laboratory testing and imaging studies (see "Laboratory Tests")

LABORATORY TESTS

- β-Human chorionic gonadotropin (HCG) test (positive in pregnancy)
- Prolactin level (elevated, often >200 ng/ml in prolactinoma but may occur at any prolactin level). Confirm with repeat fasting test (avoid exercise and breast stimulation)
- Thyroid-stimulating hormone (TSH) (elevated in hypothyroidism)
- Basic metabolic panel (BMP): Blood urea nitrogen, creatinine (elevated in renal failure), glucose (elevated in Cushing syndrome)
- Urinalysis (hematuria in renal cell carcinoma)
- Microscopic examination of nipple discharge (scant cellular material, numerous fat globules, can be seen without specific staining)

IMAGING STUDIES

- MRI of brain if prolactin level is elevated, amenorrhea is present, or visual field defects are detected on physical examination.
- High-resolution CT of brain with special coronal cuts through the pituitary region may be helpful in patients with contraindications to MRI; however, it may miss small lesions.

TREATMENT

- Discontinuation of potential offending agents
- Avoidance of excessive breast stimulation
- Galactorrhea resulting from prolactinoma can be managed medically or with careful surveillance depending on size and growth of tumor, associated symptoms, and prolactin level. Surgical treatment of prolactinomas is usually reserved for medication failures. Please refer to the topic "Prolactinoma" in Section I for additional information
- No treatment is necessary for normoprolactinemic patients with idiopathic nonbothersome galactorrhea. Provide reassurance
- Normoprolactinemic patients with bothersome galactorrhea may respond to low dose dopamine agonist (e.g., cabergoline 0.25 mg twice weekly)
- If patient is experiencing anovulatory dysfunction, consider treatment with bromocriptine (discontinue with confirmation of pregnancy)

REFERRAL

Endocrine and neurosurgical consultation if prolactinoma is detected

BASIC INFORMATION

DEFINITION

Gallbladder cancer (GBC) is a rare malignancy that originates from the epithelial lining of the gallbladder. Nearly all of these cancers are adenocarcinomas. Rare pathological types include adenosquamous carcinoma, squamous cell carcinoma, small-cell carcinoma, and carcinosarcoma.

ICD-10CM CODE
C23 Malignant neoplasm of gallbladder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- The fifth most common gastrointestinal cancer in the U.S. Over 12,000 new cases of gallbladder cancer and cancers of large bile ducts will be diagnosed in 2020, and fewer than 4 in 10 will be gallbladder cancers.
- Incidence of new cases estimated at 1 to 2 cases per 100,000 population in the U.S.
- Most prevalent in South American countries and some Asian counties, such as Japan and Korea, due to high incidence of cholelithiasis.

PREDOMINANT SEX AND AGE: Female:male ratio 2.5:1 to 3.1:1. Incidence increases with age.

GENETICS: Increased incidence occurs in hereditary syndromes such as Gardner syndrome, neurofibromatosis type I, and hereditary nonpolyposis colon cancer (HNPCC).

RISK FACTORS (BOX E1):

- Gallstone disease
- Porcelain gallbladder
- Female gender
- Older age
- Gallbladder polyps (size >1 cm)
- Primary sclerosing cholangitis
- Chronic infection from salmonella or helicobacter
- Obesity

BOX E1 Risk Factors for Gallbladder Carcinoma

Anomalous union of the pancreaticobiliary ductal system
Carcinogens*
Cholangiocarcinoma
Cholelithiasis (stone size >1 cm)
Chronic *Salmonella typhi* or *paratyphi* carrier status
First-degree relative with gallbladder cancer
IBD
Intrahepatic biliary dysplasia
Lynch syndrome
Porcelain gallbladder
PSC
Segmental adenomyomatosis in patients ≥60 yr of age

*Methylcholanthrene, O-aminoazotoluene, nitrosamines, and possibly others.
IBD, Inflammatory bowel disease; *PSC,* primary sclerosing cholangitis.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Early stage: Most patients are asymptomatic.
- Late stage: Right-upper-quadrant pain, weight loss, malaise, nausea, vomiting, and obstructive jaundice. Patients can also present with symptoms of cholecystitis including fever and pain.
- Physical exam may reveal Courvoisier law (palpable gallbladder and mild painless jaundice).
- Can often be misdiagnosed as biliary colic or cholecystitis, resulting in delayed diagnosis

ETIOLOGY/PATHOGENESIS

Chronic inflammation of gallbladder from any cause can predispose to evolution from dysplasia to carcinoma in situ to invasive cancer subsequently.

- Gallbladder cancer can spread early by hematogenous or lymphatic route or by direct invasion into the liver.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cholangiocarcinoma
- Acalculous cholecystitis
- Carcinoma of the ampulla of Vater
- Gallbladder mucocele
- Gallstones
- Gallbladder volvulus

WORKUP

- Initial work consists of laboratory evaluation and sonogram of abdomen.
- Liver function tests might reveal bile duct obstruction with an elevated serum bilirubin or alkaline phosphatase.
- Cancer antigen 19-9 (CA 19-9) or carcinoembryonic antigen (CEA) is frequently elevated, but they both have low sensitivity and specificity for diagnostic purposes.
- Suspicious ultrasonographic findings, including calcification, thickened gallbladder wall, gallbladder polyps ≥10 mm, and protruding mass, are warranted for additional imaging studies with computed tomography (CT) of abdomen (Fig. E1), magnetic resonance imaging (MRI)/magnetic resonance cholangiopancreatography (MRCP), or endoscopic ultrasonography (EUS).
- Chest CT should be done to complete staging work-up. PET/CT has limited sensitivity but high specificity in the detection of regional lymph node metastases. PET/CT may be considered when there is an equivocal finding on CT/MRI.
- Staging laparoscopy is very useful to determine resectability state.
- Staging (Table E1).

TREATMENT

- Surgery (Table E2) is the mainstay of treatment for curative intent. Incidental GBC is often operated by laparoscopic cholecystectomy and detected by pathology review postoperatively. In these cases, a radical re-resection is indicated depending on tumor stage.
- Extended cholecystectomy is the preferred approach when GBC is suspected pre-operatively.
- Adjuvant therapy:
  1. T_{1a} with negative margins: No adjuvant chemotherapy.
  2. T_{1b} or higher: Adjuvant chemotherapy with fluoropyrimidine-based or gemcitabine-based chemotherapy alone or fluoropyrimidine chemoradiotherapy.
- Unresectable or metastatic disease: Gemcitabine/cisplatin is considered first-line standard of care. Taxanes and fluoropyrimidine-containing regimens can be used upon disease progression. The role of immunotherapy and targeted agents is investigational. Pembrolizumab (PD-1 inhibitor) is appropriate for microsatellite instability high (MSI-H) tumors.
- Neoadjuvant chemotherapy may downstage select patients with unresectable disease. Reevaluation by a surgeon should be considered.
- Role of chemoradiotherapy can be considered in select cases in the adjuvant setting or as definitive management for unresectable disease.

SURVEILLANCE

- Consider imaging every 6 mo for 2 yr if clinically indicated, and then annually up to 5 yr.
- Consider CEA and CA 19-9 as clinically indicated.

TABLE E1 TNM and American Joint Committee on Cancer (AJCC)/International Union Against Cancer (UICC) Staging Systems for Gallbladder Carcinoma

TNM Stage	Criteria
T_x	Primary tumor cannot be assessed
T_0	No evidence of primary tumor
T_{is}	Carcinoma in situ
T_{1a}	Tumor invades lamina propria
T_{1b}	Tumor invades muscularis propria
T_2	Tumor invades perimuscular connective tissue without extension beyond serosa or into liver
T_3	Tumor perforates the serosa AND/OR Tumor directly invades the liver AND/OR Tumor invades one other adjacent organ (i.e., stomach, duodenum, colon, pancreas, omentum, extrahepatic bile ducts)
T_4	Tumor invades the portal vein or hepatic artery OR Tumor invades ≥2 extrahepatic organs or structures
N_x	Regional lymph nodes cannot be assessed
N_0	No regional lymph node metastases
N_1	Lymph node metastases along the cystic duct, bile duct, hepatic artery, AND/OR portal vein
N_2	Metastases to periaortic, pericaval, superior mesenteric artery, AND/OR celiac artery lymph nodes
M_0	No distant metastases
M_1	Distant metastases

AJCC/UICC Stage	Tumor	Node	Metastasis
0	T_{is}	N_0	M_0
I	T_1	N_0	M_0
II	T_2	N_0	M_0
III_A	T_3	N_0	M_0
III_B	T_{1-3}	N_1	M_0
IV_A	T_4	N_{0-1}	M_0
IV_B	Any T	N_2	M_0
	Any T	Any N	M_1

TNM, Tumor, node, metastasis.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E2 Recommended Management by Stage

Stage	Surgical Management	Postoperative Management
T_{1a}	Simple cholecystectomy	Review pathology report to confirm negative cystic duct margins No routine follow-up advised
T_{1b}	Radical cholecystectomy (i.e., segment IV_b/V resection [preferred], hepatic wedge resection, right hepatic lobectomy, or trisectionectomy with R0 resection) and portal lymphadenectomy	Staging workup with CT chest/abdomen/pelvis (or CT chest and MRI abdomen/pelvis) Adjuvant fluoropyrimidine chemoradiation versus gemcitabine-based or fluoropyrimidine-based chemotherapy Surveillance imaging
II	See earlier for T_{1b} tumors	See earlier for T_{1b} tumors
III	Consider diagnostic staging laparoscopy followed by operation for T_{1b} tumors if no metastatic disease is identified	See earlier for T_{1b} tumors
IV_A	Stage IV_A (T4 N_{0-1} M_0) disease may be amenable to resection (see stage III)	Adjuvant fluoropyrimidine chemoradiation versus gemcitabine-based or fluoropyrimidine-based chemotherapy
IV_B	N_2 and M_1 disease is a contraindication to attempts at curative resection. Patients may require palliative operation for relief of biliary obstruction but attempts at endoscopic/ percutaneous drainage should be considered first-line treatment	Unresectable disease: Combined gemcitabine/cisplatin therapy, fluoropyrimidine-based or gemcitabine-based chemotherapy regimens current

CT, Computed tomography; *MRI*, magnetic resonance imaging.

BASIC INFORMATION

DEFINITION

A fluid-filled sac (cyst) overlying a tendon sheath or joint

SYNONYM

Ganglion

ICD-10CM CODE
M67.4 Ganglion

EPIDEMIOLOGY & DEMOGRAPHICS

- Ganglia are more common in women than men (3:1).
- Can occur at any age, but usually between the second and fourth decades of life.
- Most common soft tissue tumor of the hand and wrist.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most ganglia occur on the dorsum of the wrist (50% to 70%) (Fig. E1).
- The volar wrist (18% to 20%) is the next most common site.
- Can also involve the proximal digital flexor tendons and the distal interphalangeal joints.
- Left and right hands are equally affected.
- Ganglia are usually solitary, firm, smooth, round, and fluctuant.
- Pain from mass effect or compression against nearby structure may be present (e.g., median nerve and radial nerve).

FIG. E1 Dorsal wrist ganglion. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

- Hand numbness may be present.
- Patient may have hand muscle weakness.
- Ganglia usually develop over a period of months but may arise suddenly.

ETIOLOGY

Ganglia are believed to derive from synovial herniation or expansion from the joint capsule or tendon sheath. Repetitive movement as an etiology is uncertain, although it may cause enlargement of the lesion or worsen symptoms.

DIAGNOSIS

Direct inspection and localization of the cyst often are enough to make the diagnosis of ganglia. Transillumination is an easy method of differentiating ganglia from solid tumors; ganglia transilluminate, but solid tumors do not.

DIFFERENTIAL DIAGNOSIS

- Lipoma
- Fibroma
- Epidermoid inclusion cyst
- Osteochondroma
- Hemangioma
- Infection (tuberculosis, fungi, and secondary syphilis)
- Gout
- Rheumatoid nodule
- Radial artery aneurysm

WORKUP

The workup of ganglia usually consists of history, physical examination, and occasionally radiography.

LABORATORY TESTS

Blood tests are not specific in the diagnosis of ganglia.

IMAGING STUDIES

- Radiographs of the hand and wrist are taken to rule out other bone or joint abnormalities.
- Ultrasound studies are helpful in the diagnosis of ganglia by demonstrating smooth cystic walls that may be septated.
- CT scan can be done if the ultrasound is equivocal.
- MRI helps differentiate malignant bone lesions from cystic structures.
- Arthrography may demonstrate a communication between the joint and ganglia (not commonly done).

TREATMENT

Expectant treatment is appropriate if the mass is not painful or interfering with motor function.

NONPHARMACOLOGIC THERAPY

- Attempts to rupture the cyst by sharp blows with a book or with finger compression are not recommended.
- Aspiration, heat, and sclerotherapy have been tried but have met with high recurrence rates (60%).

ACUTE GENERAL Rx

- Aspiration at the base with a large-bore needle (18-gauge) followed by injection of 20 to 40 mg of triamcinolone acetonide can be tried.
- This may be repeated if the ganglia recurs (35% to 40%).

CHRONIC Rx

Total ganglionectomy and repair of the defect after tracing its connection to the tendon sheath is effective and the surgical procedure of choice.

DISPOSITION

- Ganglia spontaneously resolve in approximately 40% to 50% of cases.
- Aspiration with steroid injection is successful in approximately 65% of cases.
- Surgery provides cure in 85% to 95% of the cases.
- Complications of ganglia include:
  1. Carpal tunnel syndrome with pain and muscle atrophy
  2. Radial nerve impingement
  3. Radial artery compression
- Complications of ganglion surgery include:
  1. Infection
  2. Recurrence (5% to 15%), usually from inadequate excision
  3. Reflex sympathetic dystrophy
  4. Scar formation

REFERRAL

It is best to refer patients with symptomatic ganglia to a hand surgeon.

PEARLS & CONSIDERATIONS

- Dorsal ganglia usually originate from the scapholunate ligament.
- Volar ganglia typically originate between the tendons of the flexor carpi radialis and brachioradialis.

COMMENTS

A ganglion's synovial membrane maintains its secretory function. Aspiration of ganglia often demonstrates a viscous, mucinous, clear fluid containing albumin, globulin, and hyaluronic acid.

BASIC INFORMATION

DEFINITION

Gastric cancer is an adenocarcinoma arising from the stomach. Cancers in the cardia arising within 5 cm of the gastroesophageal junction (GEJ) are typically classified as GEJ cancers. It is subdivided into intestinal and diffuse histology. The diffuse form of gastric cancer is more common in women and young patients, whereas the intestinal type is predominantly related to environmental factors (smoking, diet high in smoked, salted, and pickled food, nitrates and nitrites) and ethnicity (Asian and Pacific descent). The classification of gastric adenocarcinoma by depth of invasion is illustrated in Fig. 1.

SYNONYMS

Gastric adenocarcinoma
Stomach cancer
Linitis plastica

ICD-10CM CODES

C16	Malignant neoplasm of stomach
C16.0	Malignant neoplasm of cardia of stomach
C16.1	Malignant neoplasm of stomach
C16.2	Malignant neoplasm of body of stomach
C16.3	Malignant neoplasm of pyloric antrum
C16.5	Malignant neoplasm of lesser curvature of stomach, unspecified
C16.6	Malignant neoplasm of greater curvature of stomach, unspecified
C16.8	Malignant neoplasm of overlapping sites of stomach

EPIDEMIOLOGY & DEMOGRAPHICS

- Gastric cancer is the fourth commonest cancer in the world, with an annual incidence of approximately 950,000 cases annually; of these, 70% occur in developing countries. The highest incidence is in Asia and the lowest in North America. Annual estimated deaths due to gastric cancer are 723,000 worldwide.
- In the U.S., an estimated 27,510 new cases and 11,140 deaths were expected in 2019.
- The incidence of gastric cancer is 6.7 in 100,000 persons in the U.S. Mortality rate is 3.4 per 100,000 persons. Although the incidence of distal stomach tumors has greatly declined over the past 30 yr, that of proximal tumors of the cardia and fundus is on the rise.
- Gastric cancer is more common in male patients >65 yr (70% of patients are >50 yr).
- Male/female ratio is 3:2.
- Hereditary diffuse gastric cancer (HDGC) has an autosomal-dominant inheritance, and cancer develops at a young age (average age 37 yr). Germline truncating mutations in the tumor-suppressor E-cadherin gene *(CDH1)* are found in up to 50% of these families. It is associated with an 80% lifetime risk of gastric cancer.
- Increased risk of gastric cancer is also seen with Lynch syndrome, FAP, Peutz-Jeghers, juvenile polyposis syndrome, and hyperplastic gastric polyps.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Medical history may reveal complaints of postprandial fullness with significant weight loss (70% to 80%), nausea/vomiting (20% to 40%), dysphagia (20%), and dyspepsia, usually unrelieved by antacids; epigastric discomfort, usually lessened by fasting and exacerbated by food intake, is also common.
- Epigastric or abdominal mass (30% to 50%), epigastric pain.
- Iron deficiency anemia is typically seen from tumor bleeding, and hemoccult-positive stools are detected.
- Hard, nodular liver: May indicate metastatic disease to the liver.
- Ascites, lymphadenopathy, or pleural effusions: May indicate metastases.

ETIOLOGY

RISK FACTORS:

- Chronic *Helicobacter pylori* gastritis. Gastric cancer develops in persons infected with *H. pylori* but not in uninfected persons. Those with histologic findings of severe gastric atrophy, corpus-predominant gastritis, or intestinal metaplasia are at increased risk. Persons with *H. pylori* infection and duodenal ulcer are not at risk, whereas those with gastric ulcers, nonulcer dyspepsia, and gastric hyperplastic polyps are. Eradication of *H. pylori* reduces gastric cancer risk
- Tobacco abuse, heavy alcohol consumption
- Food additives (nitrosamines), smoked foods, occupational exposure to heavy metals, rubber, asbestos
- Chronic atrophic gastritis with intestinal metaplasia, hypertrophic gastritis, and pernicious anemia
- Box 1 summarizes risk factors for gastric adenocarcinoma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gastric lymphoma (5% of gastric malignancies)
- Hypertrophic gastritis
- Peptic ulcer
- Reflux esophagitis

WORKUP

Upper endoscopy (Fig. E2) with biopsy will confirm diagnosis. Endoscopic ultrasonography in combination with PET/CT scanning and operative lymph node dissection can be used in staging of the tumor. Table 1 and Fig. 1 describe staging systems for gastric carcinoma.

LABORATORY TESTS

- Complete blood count reveals microcytic anemia.
- Hemoccult-positive stools are detected.
- Chemistry tests can reveal hypoalbuminemia or abnormal liver enzymes in patients with metastasis to the liver.

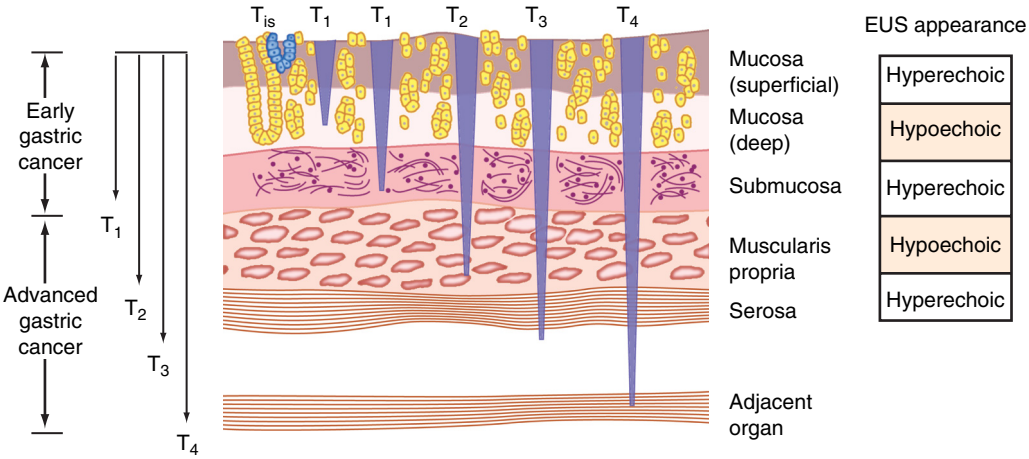

FIG. 1 Classification of gastric adenocarcinoma by depth of invasion (T classification). In the TNM classification, T denotes depth of invasion: T_{is} designates carcinoma in situ; T_1 tumors are confined to the mucosa (T_{1a}) and submucosa (T_{1b}); T_2 tumors invade the muscularis propria but not the serosa; T_3 tumors penetrate the subserosal connective tissue without involving the visceral peritoneum or contiguous structures; and T_4 tumors invade the serosa (visceral peritoneum) and may involve adjacent organs and tissues. In early gastric cancer, the disease is confined to the mucosa and submucosa (T_1), regardless of nodal involvement. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Saunders.)

BOX 1 Risk Factors for Gastric Adenocarcinoma

Definite
H. pylori infection
Chronic atrophic gastritis
Intestinal metaplasia
Dysplasia*
Adenomatous gastric polyps
Cigarette smoking
History of gastric surgery (especially Billroth II)
Genetic factors:
- Family history of gastric cancer (first-degree relative)
- Familial adenomatous polyposis (with fundic gland polyps)
- Hereditary nonpolyposis colorectal cancer
- Peutz-Jeghers syndrome
- Juvenile polyposis

Probable
High salt intake
Obesity (adenocarcinoma of the cardia only)
Snuff tobacco use
History of gastric ulcer
Pernicious anemia
Regular aspirin or other NSAID use (protective)

Possible
Statin use (protective)
Heavy alcohol use
Low socioeconomic status
Ménétrier disease
High intake of fresh fruits and vegetables (protective)
High ascorbate intake (protective)

Questionable
Hyperplastic and fundic gland polyps
Diet high in nitrates
High green tea consumption (protective)

*Surveillance for cancer is recommended in patients with this risk factor.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Saunders.

TABLE 1 TNM Staging Criteria and Stages for Gastric Carcinoma Based on AJCC 8th Edition

T Category	T Criteria
T_X	Primary tumor cannot be assessed
T_0	No evidence of primary tumor
T_{is}	Carcinoma *in situ*: Intraepithelial tumor without invasion of the lamina propria, high-grade dysplasia
T_1	Tumor invades the lamina propria, muscularis mucosae, or submucosa
T_{1a}	Tumor invades the lamina propria or muscularis mucosae
T_{1b}	Tumor invades the submucosa
T_2	Tumor invades the muscularis propria
T_3	Tumor penetrates the subserosal connective tissue without invasion of the visceral peritoneum or adjacent structures
T_4	Tumor invades the serosa (visceral peritoneum) or adjacent structures
T_{4a}	Tumor invades the serosa (visceral peritoneum)
N Category	**N Criteria**
N_X	Regional lymph node(s) cannot be assessed
N_0	No regional lymph node metastasis
N_1	Metastasis in one or two regional lymph nodes
N_2	Metastasis in three to six regional lymph nodes
N_3	Metastasis in seven or more regional lymph nodes
N_{3a}	Metastasis in 7 to 15 regional lymph nodes
M Category	**M Criteria**
M_0	No distant metastasis
M_1	Distant metastasis

Stage	pT	pN	M
Stage 0	T_{is}	N_0	M_0
Stage IA	T_1	N_0	M_0
Stage IB	T_1	N_1	M_0
	T_2	N_0	M_0

	T_{4a}	N_{3b}	M_0
	T_{4b}	N_{3a} or N_{3b}	M_0
Stage IV	Any T	Any N	M_1

- Up to 25% of gastric cancers overexpress the HER2/neu growth factor receptor, and it is now standard practice to evaluate gastroesophageal tumors for HER2 overexpression.
- Mutation-specific predictive genetic testing by polymerase chain reaction amplification followed by restriction: Enzyme digestion and DNA sequencing for truncating mutations in *CDH1* is recommended in families of patients with familial diffuse cancer because gastric cancer develops in three of every four carriers of a mutant *CDH1* gene. Genetic abnormalities in gastric adenocarcinoma are summarized in Table E2.

IMAGING STUDIES

Chest and abdomen PET/CT scan (Fig. E3) to evaluate for metastases

Rx TREATMENT

ACUTE GENERAL Rx

- Gastrectomy: Most curable tumors can be removed with adequate margins by subtotal gastrectomy; total gastrectomy is used when mandated by proximal cancer location or disease extent. The preferred treatment for lesions arising in the body or antrum of the stomach is a radical distal subtotal resection (Fig. E4). This procedure removes approximately 80% of the stomach, along with the first portion of the duodenum, the gastrohepatic and gastrocolic omenta, and the nodal tissue adjacent to the three branches of the celiac axis. Extensive or proximal cancers require a total gastrectomy to achieve an adequate proximal gastric margin (Fig. E5). If total gastrectomy is necessary, a splenectomy is sometimes performed, particularly in gastric cancers of the proximal third of the stomach and tumors of the body near the greater curvature. These cancers are more apt to metastasize to lymph nodes in the splenic hilum that cannot be completely excised without a splenectomy. Routine splenectomy is no longer practiced because of

the increased complications. A splenectomy should be performed when worrisome, palpable nodes are present in the splenic hilum.
- In advanced cases, palliative gastrectomy (bleeding, obstruction) can be performed. Outlet obstruction can be addressed by performing a gastrojejunostomy.
- In patients with operable gastric cancer, the perioperative regimen chemotherapy can decrease tumor size and stage while improving progression-free and overall survival. The current standard neoadjuvant regimen in use is the FLOT (5-fluorouracil [5-FU], leucovorin, oxaliplatin, docetaxel) regimen.
- Postoperative adjuvant chemoradiotherapy using the older 5-FU and leucovorin regimen is an option for stage II to III patients. Alternatively, the modern approach is combination chemotherapy with FOLFOX (5-FU, leucovorin, oxaliplatin) or CAPOX (capecitabine, oxaliplatin) regimens with radiotherapy reserved for high-risk patients only.
- In metastatic gastric cancer, the use of chemotherapy with triplet or doublet regimens results in improved overall survival. In the subset of patients with gastric cancer expressing *HER2-2/neu* oncogene (20% to 25% of patients), the addition of trastuzumab to platinum plus 5-FU or capecitabine prolongs overall survival.
- Patients progressing after first-line chemotherapy can derive a survival benefit with the use of chemotherapy in combination with antivascular endothelial growth factor receptor-2 antibody ramucirumab. Immunotherapy with program death receptor-1 antibodies (nivolumab, pembrolizumab) has been shown to improve survival in previously treated patients with high-MSI tumors.
- Treatment algorithms for newly diagnosed gastric or gastroesophageal junction cancer are illustrated in Figs. 6 and 7.

DISPOSITION

- Median survival rate of metastatic or recurrent gastric carcinoma is 10 to 15 mo overall.
- The 5-yr survival for early gastric cancers is >35%.

PEARLS & CONSIDERATIONS

COMMENTS

- Gastrectomy patients will need vitamin B_{12} replacement. They are also at risk for dumping syndrome and should be advised to ingest frequent, small meals.
- Prophylactic gastrectomy should be considered in young, asymptomatic carriers of germ-line truncating *CDH1* mutations who belong to families with highly penetrant heredity diffuse gastric cancer.
- Gastric cancer screening for average-risk patients is not recommended in the U.S.

FIG. E2 Polypoid gastric cancer. A trilobed polyp is apparent at the angularis. (From Feldman M et al [eds]: *Sleisenger & Fordtran's gastrointestinal and liver disease: pathophysiology/diagnosis/management,* ed 8, Philadelphia, 2006, Saunders.)

TABLE E2 Genetic Abnormalities in Gastric Adenocarcinoma

Abnormalities	Approximate Gene Frequency (%)
Microsatellite instability	15-50
DNA aneuploidy	60-75
Deletion/Suppression	
p53 (tumor protein 53)	60-70
FHIT (fragile histidine triad gene)	60
APC (adenomatous polyposis coli gene) loss of heterozygosity	50
DCC (deleted in colorectal cancer gene) loss of heterozygosity	50
Decreased Expression Due to Hypermethylation	
p16	≈50
TFF1 (human trefoil factor 1 gene)	≈50
p27	<50
MLH1 (human mutL homolog 1 gene)	15-20
E-cadherin	50
Amplification/Overexpression	
COX-2 (cyclooxygenase-2)	70
HGF (hepatocyte growth factor)	60
VEGF (vascular endothelial growth factor)	50
c-met	50
AIB-1 (amplified in breast cancer-1)	40
beta-Catenin	25
EGFR (EGF receptor gene)	15
Mutations	
PI3K (phosphatidylinositol 3-kinase gene)	25
PTPRT (protein-tyrosine phosphatase receptor type gene)	17

From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Saunders.

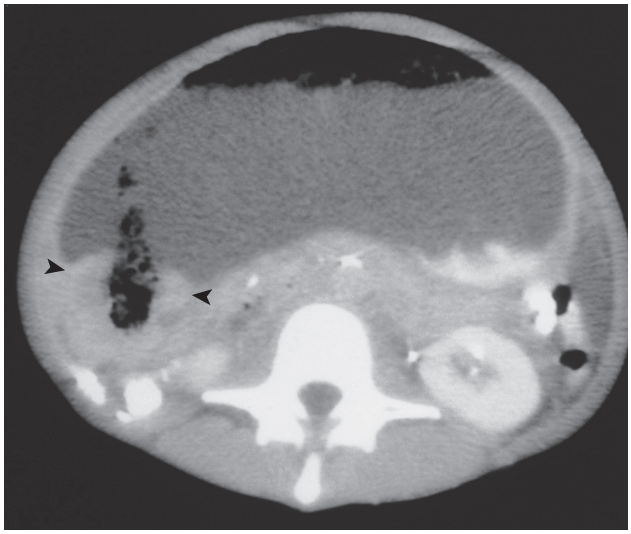

FIG. E3 Gastric outlet obstruction: cancer of the antrum. A markedly distended stomach with an air-fluid level is seen on computed tomography. In this case, a mass in the distal end of the antrum is apparent *(arrowheads).* (From Grainger RG et al [eds]: *Grainger & Allison's diagnostic radiology: a textbook of medical imaging,* ed 4, St Louis, 2001, Churchill Livingstone.)

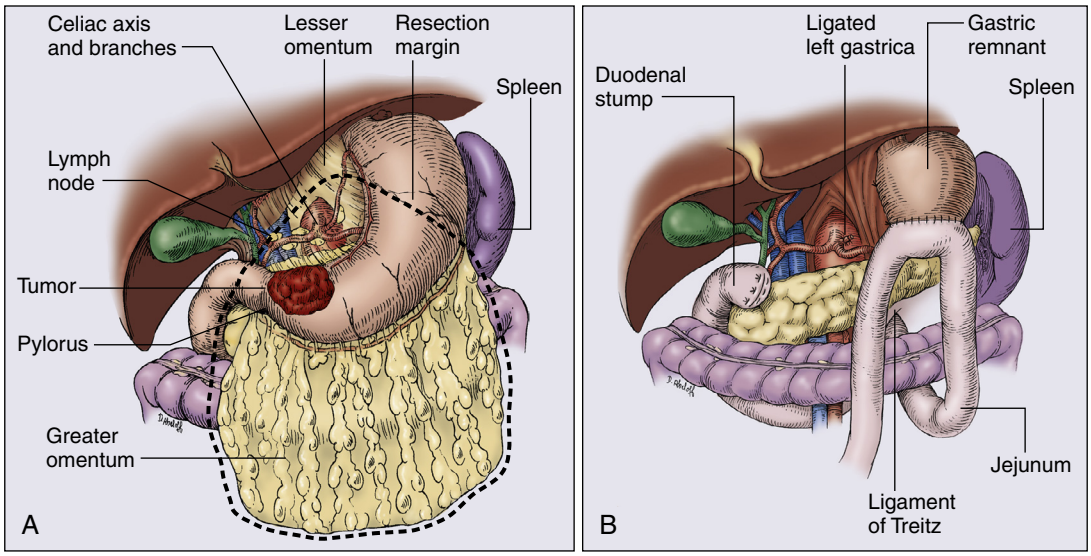

FIG. E4 A, Radical subtotal gastrectomy. The extent of resection for this tumor of the antrum includes the distal 80% of the stomach; the lesser and greater omenta; the perigastric lymph nodes (Japan N1); and lymph nodes along the left gastric, celiac, and common hepatic arteries (Japan N2). **B,** Radical subtotal gastrectomy reconstruction. After closure of the duodenal stump and lesser curvature of the stomach, the gastric remnant and proximal jejunum are anastomosed end to side in an antecolic position. The spleen and distal pancreas have been left in situ. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

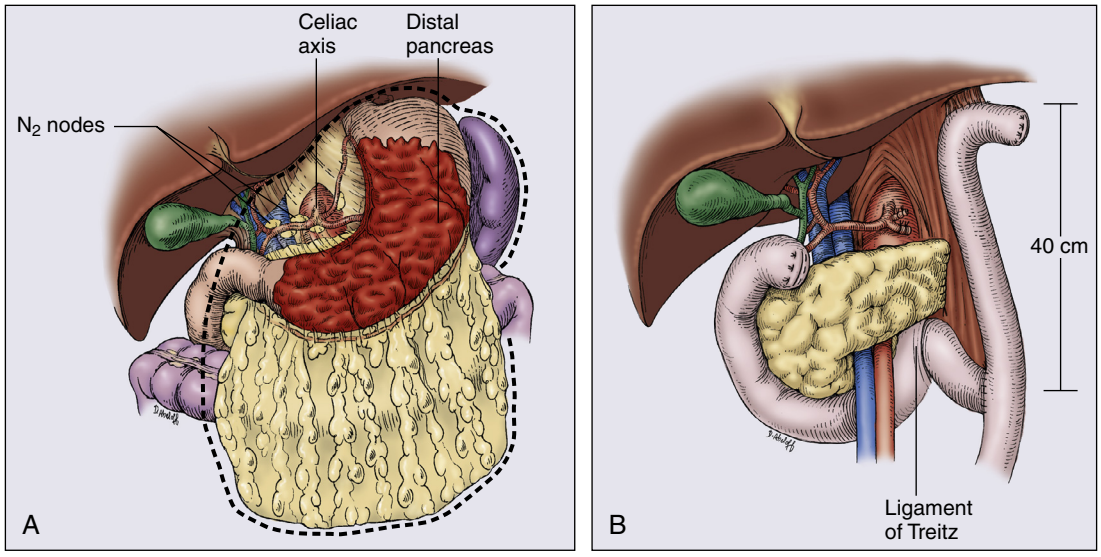

FIG. E5 A, Radical total gastrectomy. A total gastrectomy is indicated for this extensive tumor of the stomach. Both omenta, the spleen, distal pancreas, and Japan N_2 lymph nodes are to be included with the operative specimen. **B,** Radical total gastrectomy reconstruction. Although a variety of anastomoses and jejunal pouches have been described, no benefit seems to accrue from any approach, except to keep the biliary and pancreatic secretions away from the esophageal mucosa. The Cohn end-to-side Roux-en-Y esophagojejunostomy with a 40-cm limb is depicted. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

Gastrinoma ALG PTG

BASIC INFORMATION

DEFINITION

A gastrinoma is a neuroendocrine tumor that secretes gastrin with a resultant hypergastrinemic state, which results in severe peptic ulcer disease with diarrhea, and this is also known as Zollinger-Ellison syndrome (ZES).

SYNONYMS

Zollinger-Ellison (ZE) syndrome
Zes

ICD-10CM CODES

C25.4	Malignant neoplasm of endocrine pancreas
E16.4	Abnormal secretion of gastrin

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence is unknown, but there is consensus that approximately 0.5 to 3 persons per million develop gastrinoma each yr in most geographical areas.
- Females have a slightly greater preponderance for developing the disease, and gastrinoma is most frequently diagnosed between the ages of 20 and 50 yr.
- Two thirds of gastrinomas are sporadic, and one third are associated with multiple endocrine neoplasia type 1 (MEN-1), an autosomal-dominant genetic disorder that also includes hyperparathyroidism and pituitary tumors.
- Approximately 60% of gastrinomas are malignant.
- The incidence and prevalence of pancreatic neuroendocrine tumors are increasing. They represent 1.3% of all cases of pancreatic cancer.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The majority of patients (95%) present with symptoms of peptic ulcer (see Section I, "Peptic Ulcer Disease").
- 60% of patients have symptoms related to gastroesophageal reflux disease (see Section I, "Gastroesophageal Reflux Disease").
- One third of patients with ZE have diarrhea and, less commonly, steatorrhea.

The following circumstances warrant suspicion of ZE syndrome:

- Ulcers distal to the first portion of the duodenum
- Multiple peptic ulcers
- Ineffective treatment for peptic ulcer disease with the usual drug doses and schedules
- Peptic ulcer and diarrhea
- Familial history of peptic ulcer
- Patients with a personal or family history suggesting parathyroid or pituitary tumors or dysfunction
- Peptic ulcer and urinary tract calculi
- Patients with peptic ulcer who are negative for *Helicobacter pylori* and do not have a history of nonsteroidal antiinflammatory drug use

ETIOLOGY

- Gastrinomas are derived from the enteroendocrine cells that arise from the embryologic endoderm and form tumors mainly in the pancreas but also in the proximal small intestine. They are classified as well-differentiated neuroendocrine tumors (NETs).
- The pathophysiologic manifestations of ZE syndrome are related to the effects of hypergastrinemia. Gastrin stimulates gastric acid secretion, which in turn is responsible for the development of duodenal ulcers and diarrhea. Gastrin also promotes gastric mucosal epithelial cell growth and resulting parietal cell hyperplasia.
- Gastrinomas are usually small (0.1 to 2 cm) but sometimes large (>20 cm) tumors.
- 60% of gastrinomas are malignant, with liver and regional lymph nodes the most common site of metastases. Histology is not a good predictor of the biology of gastrinomas.
- 60% of patients with MEN-1 have gastrinomas.
- 10% of patients with ZE syndrome have islet cell hyperplasia rather than gastrinomas; in 10% to 20% of patients, tumors cannot be located because of their small size.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer disease (see Section I, "Peptic Ulcer Disease")
- Gastroesophageal reflux disease (see Section I, "Gastroesophageal Reflux Disease")
- Other endocrine tumors of the pancreas (see Table E1)

WORKUP

- Fig. E1 illustrates an algorithm for the diagnosis of ZES. Sensitivities of gastrinoma

TABLE E1 Characteristics of Endocrine Tumors of the Pancreas

Tumor Type	Major Clinical Symptoms	Predominant Hormone	Islet Cell Type	Malignant (%)	Localization	Other Clinical Features
Insulinoma	Hypoglycemia (fasting or nocturnal)	Insulin	β	10	Usually pancreatic; rarely extrapancreatic	Catecholamine excess
Glucagonoma	1. Diabetes mellitus 2. Migratory necrolytic erythema	Glucagon	α	90	Usually pancreatic; rarely extrapancreatic	Panhypoaminoaciduria Thromboembolism Weight loss
Gastrinoma	Recurrent peptic ulcer disease	Gastrin	γ	90	Usually pancreatic but frequently extrapancreatic	Diarrhea/steatorrhea
Somatostatinoma	1. Diabetes mellitus 2. Diarrhea, steatorrhea	Somatostatin	δ	80	Pancreatic and duodenal	Hypochlorhydria Weight loss Gallbladder disease
VIPoma	Watery diarrhea, hypokalemia, achlorhydria (WDHA syndrome)	Vasoactive intestinal polypeptide (VIP)	δ	50	Usually pancreatic but frequently extrapancreatic	Metabolic acidosis Hyperglycemia Hypercalcemia Flushing
PPoma	1. Hepatomegaly 2. Abdominal pain	Pancreatic polypeptide (PP)	PP cells	80	Usually pancreatic; rarely extrapancreatic	Occasional watery diarrhea

From Besser GM, Cudworth AG: *Clinical endocrinology,* Philadelphia, 1987, Lippincott/Gower Medical Publishing, p. 20.

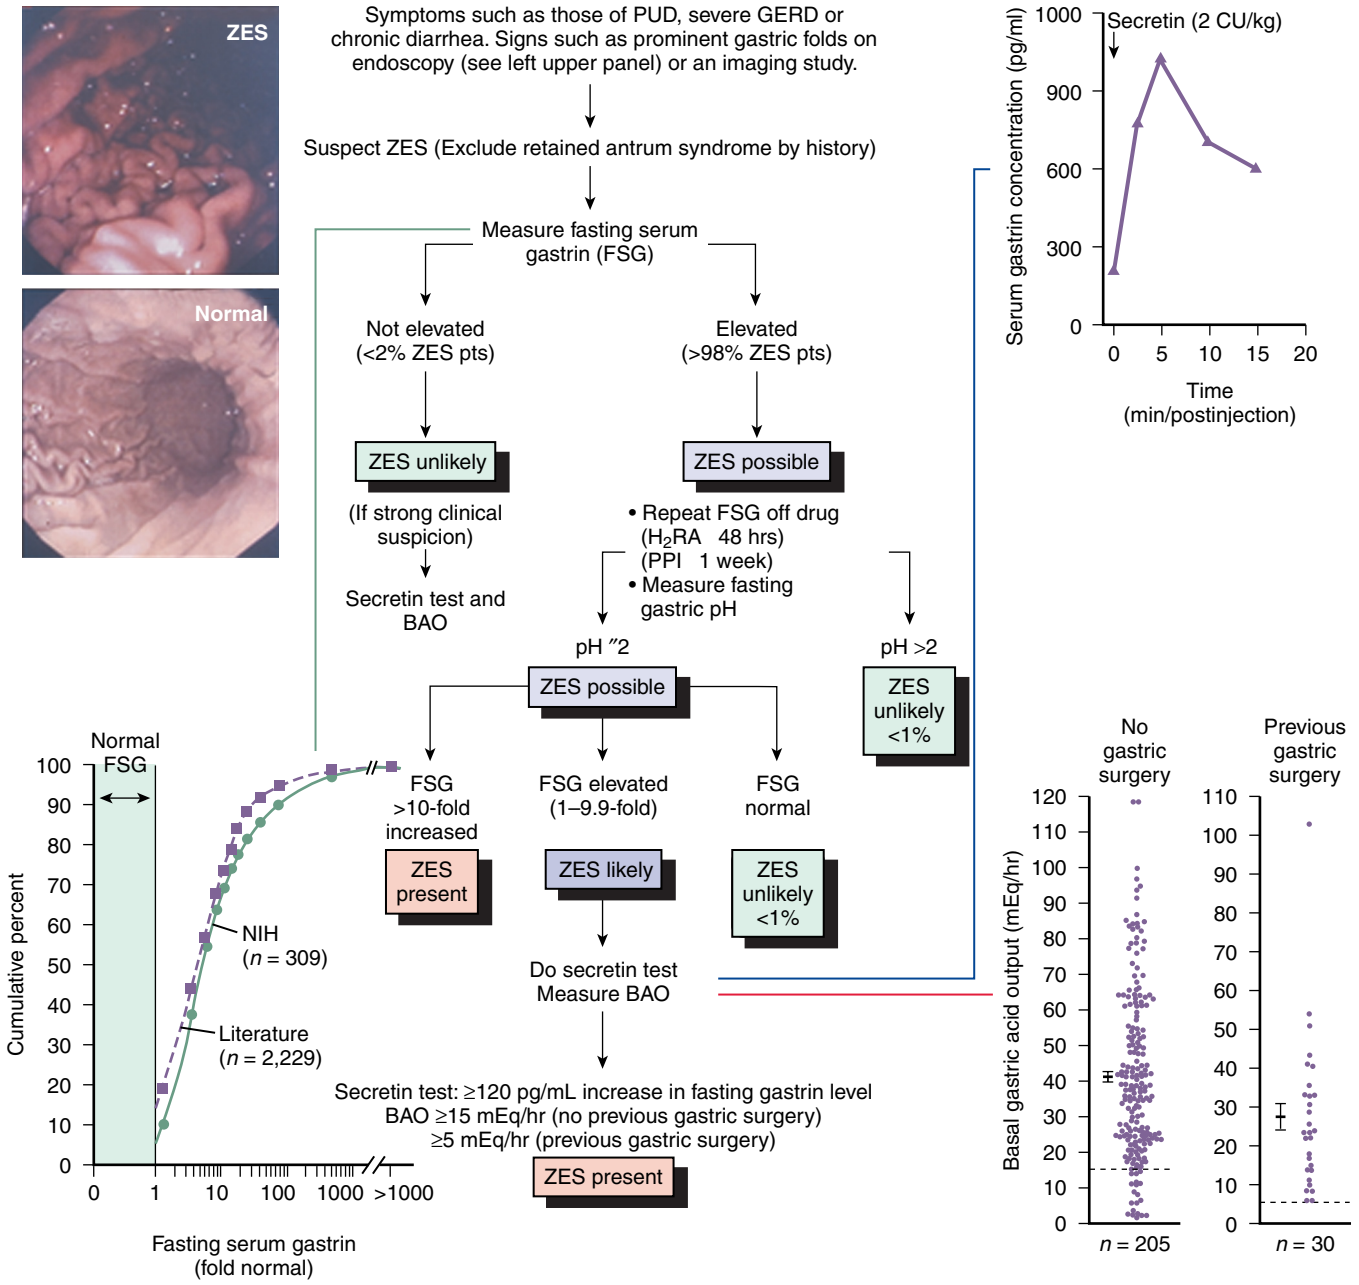

FIG. E1 Algorithm for the diagnosis of Zollinger-Ellison syndrome *(ZES).* *Right upper,* Typical ZES patient with a positive secretin test result (i.e., ≥120-pg/ml increase in fasting gastrin level). *Right lower,* Marked elevations in mean basal acid output (BAO) with or without previous gastric acid–reducing surgery. The dotted horizontal lines show the proposed criterion of >15 mEq/hr or >5 mEq/hr proposed to distinguish patients with ZES from those without ZES. *Left upper,* Prominent gastric folds found on endoscopy in a ZES patient, compared with a normal subject. *Left lower,* Fasting serum gastrin levels in ZES expressed as a multiple of the upper limit of normal on the horizontal axis. Very few patients had normal values; 60% had less than tenfold serum gastrin increases. *CU,* Clinical units. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Saunders.)

localization studies are summarized in Table E2

- Diagnosis of peptic ulcer:
  1. Endoscopy
- Gastric acid secretion:
  1. Serum gastrin level (fasting) >150 pg/ml (criterion for diagnosis is serum gastrin >1000 pg/ml) (causes of false-positive results: Pernicious anemia, renal failure, retained gastric antrum syndrome, diabetes mellitus, rheumatoid arthritis)
- Provocative gastrin level tests:
  1. Secretin stimulation
  2. Calcium stimulation
  3. Standard test meal stimulation
- Gastrinoma localization:
  1. Arteriography
  2. Abdominal sonography
  3. Abdominal CT scan
  4. Abdominal MRI/PET scan
  5. Selective portal vein branch gastrin level
  6. Octreotide scan

Rx TREATMENT

- Surgical resection of the gastrinoma (note: 90% of gastrinomas can be located, resulting in a 40% overall cure rate).
- Total gastrectomy or vagotomy (palliative in some patients).
- Medical treatment:

TABLE E2 Sensitivities of Gastrinoma Localization Studies

Study	% of Tumors Localized			
	Overall	Pancreas	Duodenum	Liver Metastases
Preoperative				
Noninvasive				
Transabdominal ultrasonography	20-30			14
Abdominal computed tomography	50	80	35	50
Abdominal magnetic resonance imaging	25			83
Octreoscan	71-90		50	
DOTA scan	>90	>90	>60-90	>90
Invasive				
Endoscopic ultrasonography	85	75-100	28-57	
Intraoperative				
Palpation	65	91	60	
Intraoperative ultrasonography	83	95	58	
Duodenotomy	–	–	100	

From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.

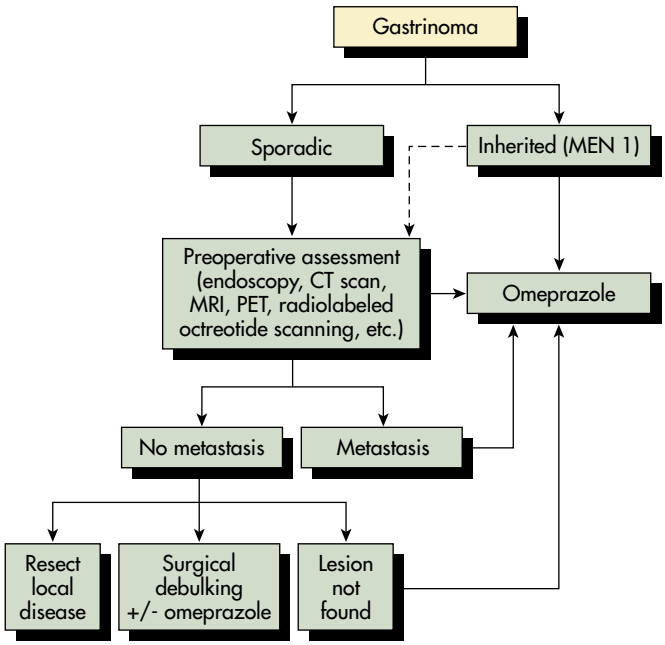

FIG. E2 Treatment algorithm for the management of a patient with gastrinoma. In some circumstances, patients with familial gastrinoma may also be candidates for surgical resection if disease is highly limited *(dotted line)*. *CT,* Computed tomography; *MEN 1,* multiple endocrine neoplasia type 1; *MRI,* magnetic resonance imaging; *PET,* positron emission tomography. (From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.)

1. Proton pump inhibitors (e.g., omeprazole, lansoprazole) is the mainstay of therapy.
2. Somatostatin or octreotide has an antiproliferative effect and controls diarrhea symptoms.
3. Targeted therapy: Everolimus, an oral inhibitor of mammalian target of rapamycin (mTOR), has shown a survival benefit in patients with advanced pancreatic neuroendocrine tumors, with low rates of severe adverse events. Another oral tyrosine kinase inhibitor, sunitinib, has also shown encouraging results on prolongation of survival in this setting.
4. The use of a radioactive-labeled isotope lutetium Lu 177-dotatate has demonstrated a survival benefit in gastroenteric-pancreatic neuroendocrine tumors. It binds to somatostatin receptors to deliver radiation directly into tumor cells and is superior to octreotide depot in this setting.
5. Chemotherapy for metastatic gastrinoma with streptozotocin, 5-fluorouracil, and doxorubicin is of limited benefit.

- Fig. E2 describes a treatment algorithm for gastrinoma.

PROGNOSIS

Five-yr survival:

- Two thirds of all patients
- 20% with liver metastases
- 90% without liver metastases

REFERRAL

To gastroenterologist, surgeon, and medical oncologist (upon development of metastatic disease)

BASIC INFORMATION

DEFINITION

Histologically, *gastritis* refers to inflammation in the stomach. Endoscopically, gastritis refers to a number of abnormal features such as erythema, erosions, and subepithelial hemorrhages. Gastritis can also be subdivided into erosive, nonerosive, and specific types of gastritis with distinctive features both endoscopically and histologically.

SYNONYMS

Erosive gastritis
Hemorrhagic gastritis
Helicobacter pylori gastritis

ICD-10CM CODES

K29.00	Acute gastritis without bleeding
K29.01	Acute gastritis with bleeding
K29.20	Alcoholic gastritis without bleeding
K29.21	Alcoholic gastritis with bleeding
K29.30	Chronic superficial gastritis without bleeding
K29.31	Chronic superficial gastritis with bleeding
K29.40	Chronic atrophic gastritis without bleeding
K29.41	Chronic atrophic gastritis with bleeding
K29.50	Unspecified chronic gastritis without bleeding
K29.51	Unspecified chronic gastritis with bleeding
K29.60	Other gastritis without bleeding
K29.61	Other gastritis with bleeding
K29.70	Gastritis, unspecified, without bleeding
K29.71	Gastritis, unspecified, with bleeding
K52.81	Eosinophilic gastritis or gastroenteritis

EPIDEMIOLOGY & DEMOGRAPHICS

- Erosive and hemorrhagic gastritis is most commonly seen in patients taking nonsteroidal antiinflammatory drugs (NSAIDs), alcoholics, and critically ill patients (usually on ventilator support).
- *H. pylori* infection with gastritis is believed to be present in 30% to 50% of the population; however, the majority are asymptomatic.
- The prevalence of *H. pylori* infection increases with age from <10% in whites <40 yr to >50% in patients >50 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with gastritis generally present with nonspecific clinical signs and symptoms (e.g., epigastric pain, abdominal tenderness, bloating, anorexia, nausea [with or without vomiting]). Symptoms may be aggravated by eating
- Epigastric tenderness in acute alcoholic gastritis (may be absent in chronic gastritis)
- Foul-smelling breath
- Hematemesis ("coffee grounds" emesis)

ETIOLOGY

- Alcohol, NSAIDs, stress (critically ill patients usually on mechanical respiration), hepatic or renal failure, multiorgan failure
- *H. pylori* infection
- Bile reflux, pancreatic enzyme reflux
- Gastric mucosal atrophy, portal hypertension gastropathy
- Irradiation

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer disease
- Gastroesophageal reflux disease
- Nonulcer dyspepsia
- Gastric lymphoma or carcinoma
- Pancreatitis
- Gastroparesis

WORKUP

Diagnostic workup includes a comprehensive history and endoscopy with biopsy.

LABORATORY TESTS

- *H. pylori* testing by urea breath test, stool antigen test (*H. pylori* stool antigen), endoscopic biopsy, or specific antibody test is recommended.
  1. The urea breath test documents active infection (sensitivity and specificity >90%). It uses a flat breath card read by a small analyzer.
  2. The stool antigen test is an enzymatic immunoassay (ELISA) that identifies *H. pylori* antigen in a stool specimen with a polyclonal anti–*H. pylori* antibody. It is as accurate as the urea breath test for diagnosis of active infection and follow-up evaluation of patients treated for *H. pylori.* A negative result on the stool antigen test 8 wk after completion of therapy identifies patients in whom eradication of *H. pylori* was successful.
  3. Histologic evaluation of endoscopic biopsy samples is considered by many the gold standard for accurate diagnosis of *H. pylori* infection. However, detection of *H. pylori* depends on the site and number of biopsy samples, the method of staining, and experience of the pathologist.
  4. Serologic testing for antibodies to *H. pylori* is easy and inexpensive; however, the presence of antibodies demonstrates previous but not necessarily current infection. Antibodies to *H. pylori* can remain elevated for months to yrs after infection has cleared; therefore antibody levels must be interpreted in light of patient's symptoms and other test results (e.g., peptic ulcer disease [PUD] seen on upper gastrointestinal series).
- Vitamin B_{12} level in patients with atrophic gastritis.
- Hematocrit (low if significant bleeding has occurred).

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of mucosal irritants such as alcohol and NSAIDs
- Lifestyle modifications with avoidance of tobacco and foods that trigger symptoms

ACUTE GENERAL Rx

- Eradication of *H. pylori,* when present, can be accomplished with various regimens:
  1. Quadruple therapy: Proton pump inhibitor (PPI) (omeprazole 20 mg, lansoprazole 30 mg, pantoprazole 40 mg, rabeprazole 20 mg) bid *plus* clarithromycin 500 mg BID plus amoxicillin 1000 mg bid *plus* metronidazole 500 mg BID for 14 days.
  2. Triple therapy: PPI bid *plus* clarithromycin 500 mg bid *and* metronidazole 500 mg bid for 14 days. This regimen is useful in those with penicillin allergy.
  3. Triple therapy: Clarithromycin 500 mg BID plus amoxicillin 1 g BID plus PPI BID for 14 days. Useful only in areas with clarithromycin resistance <15%.
  4. Bismuth quadruple therapy: Bismuth subsalicylate (e.g., Pepto-Bismol) 525 mg QID plus metronidazole 500 mg QID plus tetracycline 500 mg QID plus PPI BID for 14 days.
- Prophylaxis and treatment of stress gastritis with sucralfate suspension 1 g orally q4 to 6h, H_2-receptor antagonists, or PPIs in patients on ventilator support.

CHRONIC Rx

- Omeprazole, H2RB, or sucralfate in patients receiving long-term NSAIDs.
- Avoidance of alcohol, tobacco, and prolonged NSAID or corticosteroid use.

DISPOSITION

- Patients should be tested for eradication ≥4 weeks after completion of therapy. Undetectable stool antigen tested at least 4 wk after therapy accurately confirms cure of *H. pylori* infection in initially seropositive healthy subjects with reasonable sensitivity. PPI therapy should be stopped at least 2 wk prior to testing.
- Surveillance gastroscopy in patients with atrophic gastritis (increased risk of gastric cancer).

Gastritis (Patient Information)
Helicobacter pylori Infection (Related Key Topic)
Peptic Ulcer Disease (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

- Gastroenteritis is a broad term used for various gastrointestinal pathologic states. The main manifestation is diarrhea, defined as daily stool of at least 200 g, often accompanied by nausea, vomiting, malaise, anorexia, fever, abdominal pain, and dehydration. Gastroenteritis is usually self-limited, but if it is not managed properly, it can lead to a prolonged course. It usually lasts less than 7 days and not longer than 2 weeks. Diarrhea lasting more than 14 days is chronic or persistent.
- May be caused by viruses, bacteria, or parasites. Viruses are responsible for acute gastroenteritis in most patients.
- Gastroenteritis is a common cause of morbidity/mortality around the world. In the developing world, it is a leading cause of death.

ICD-10CM CODES

K52.9	Non-infective gastroenteritis and colitis
558.3	Allergic gastroenteritis and colitis
K52.1	Infectious gastroenteritis and colitis
K52.0	Gastroenteritis and colitis due to radiation

EPIDEMIOLOGY & DEMOGRAPHICS

- Frequency is difficult to determine. Gastroenteritis is underreported in adults. It accounts for about 250,000 hospitalizations each yr.
- Statistics on sporadic cases of adult viral gastroenteritis are not known. Norovirus is the leading cause of medically attended acute gastroenteritis in U.S. children and is associated with nearly 1 million health care visits annually.
- It is estimated that there are 1.5 billion cases a yr worldwide.
- It is the leading cause of death in many developing countries. Children under the age of 5 yr are most vulnerable.
- Viral gastroenteritis may be transmitted by the fecal-oral route, by asymptomatic carriers, or by symptomatic patients before the symptoms start.
- Traveler diarrhea affects 20% to 50% of residents of industrialized countries who travel to developing countries.

PREDOMINANT SEX:

- No sexual predilection
- Higher mortality seen in women
- Females have a higher incidence of *Campylobacter* infections

PREDOMINANT AGE:

- May occur at any age
- High morbidity and mortality in the very young (younger than 5 yr), the elderly (people aged 65 or older), and the immunosuppressed

RISK FACTORS

- Use of proton pump inhibitors (PPI) may increase the risk of developing gastroenteritis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Diagnosis is made clinically. Laboratory studies are not routinely necessary.
- A well-taken history is important. The onset, duration, and frequency of diarrhea should be noted. The aim of the physical examination is to assess the patient's degree of hydration. This also helps to identify the cause of diarrhea and identify patients at risk of complications.
- Viral gastroenteritis has a short prodrome with vomiting, mild fever, and nonbloody and watery diarrhea, usually for 1 to 4 days.
- Bacterial gastroenteritis presents with high fever, bloody diarrhea, severe abdominal pain, and at least 6 stools in a 24-hour period.
- Patients usually present with:
  1. Diarrhea: Usually more than 6 stools a day indicates bacterial cause of gastroenteritis.
  2. Vomiting.
  3. Abdominal pain.
  4. Mucus and/or blood in stool: Indicating bacterial or parasitic infection.
  5. Fever.
  6. Dehydration: This is the main cause of morbidity and mortality. Check for lethargy, dry mucous membrane, poor skin turgor, sunken eyes as signs of dehydration.
  7. Malnutrition: This occurs when diarrhea is chronic. There is reduced muscle and fat mass.
  8. Abdominal pain: This is a very common symptom in gastroenteritis.
  9. Borborygmi: There is significantly increased peristaltic activity, which may cause audible or palpable bowel activity.
  10. Perianal erythema: Secondary to constantly wet area. Wet buttock and perianal area may result in redness and skin breakdown.

ETIOLOGY

- Viral gastroenteritis (in adults)
  1. The caliciviruses, such as *Norovirus* genogroup I (e.g., Norwalk), *Norovirus* genogroup II (e.g., South Hampton), *Sapovirus* (e.g., Sapporo)
  2. Nongroup A *Rotavirus*
  3. *Astrovirus*
  4. Adenovirus
- Bacterial gastroenteritis: The top three leading causes of bacterial diarrhea worldwide are *Salmonella, Shigella,* and *Campylobacter* spp.
  1. *Salmonella* (eggs, dairy)
  2. *Shigella*
  3. *Campylobacter* (dairy, poultry)
  4. *Aeromonas species* (seafood, oysters)
  5. *Yersinia* (pork)
  6. Enterohemorrhagic *Escherichia coli* (ground beef)
  7. E. coli
  8. *Clostridium perfringens* (pork, vegetables)
- Parasitic gastroenteritis
  1. *Giardia*
  2. *Cryptosporidium*
  3. *Microsporidia*
  4. *Cyclospora*
- Traveler diarrhea
  1. Usually caused by Enterotoxigenic *E. coli,* but other organisms implicated include *Salmonella, Shigella,* and *Campylobacter*.
  2. Risk is highest in travelers to Africa, but it is also common in travelers to Portugal, Spain, and some Eastern European countries.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Amebiasis
- Appendicitis
- Celiac disease
- Inflammatory bowel disease (ulcerative colitis, Crohn disease)
- Colon cancer
- Bowel obstruction
- Botulism
- Hemolytic uremic syndrome
- Food poisoning
- Intraabdominal abscess
- Cholera

WORKUP

- In most cases laboratory tests are not indicated.
- Further workup is indicated in patients who:
  1. Have persistent diarrhea
  2. Are extremely dehydrated
  3. Appear seriously ill
  4. Have high fever
  5. Present with severe abdominal pain
  6. Have bloody diarrhea
  7. Have persistent nausea

LABORATORY TESTS

- Routine laboratory tests:
  1. Tests such as CBC and BMP may not be indicated in making a diagnosis. However, electrolytes and BUN are indicated in patients with severe diarrhea or dehydration.
  2. CBC is indicated with severe diarrhea or toxicity. WBC is increased in *Salmonella* infection; eosinophilia is present in parasitic infections.
- Stool studies:
  1. Presence of blood/leukocytes in stool may indicate inflammatory diarrhea.
  2. In *Salmonella* or *Shigella* infections there is an increased fecal leukocyte.
  3. Stool leukocytes are absent in viral diarrhea.
- Stool culture:
  1. Are only useful when positive
  2. Usually not necessary in most cases of diarrhea
  3. Indications for stool cultures include: Bloody stools; prolonged, untreated diarrhea; fever; leukocytes in stool; immunosuppressed patients; immunocompromised patients; and patients who have traveled to remote, exotic, or developing nations. It should also be considered in patients with concurrent or very recent use of antibiotics to rule out *Clostridium difficile* infection as a cause of the diarrhea

- Examination for ova and parasites (O&P) is indicated in immunosuppressed patients, immunocompromised patients, and patients who have traveled to remote, exotic, or developing nations.

IMAGING STUDIES

- In patients with suspected bowel obstruction, perforation, or toxic megacolon, abdominal series is warranted.
- Consider CT scan of the abdomen in older patients with severe abdominal pain.

Rx TREATMENT

GENERAL CONSIDERATIONS

- Most infectious diarrhea is self-limited. Medical care is mainly supportive. Fig. E1 describes an approach to the management of gastroenteritis.
- It is important to assess the degree of dehydration by checking BP, pulse, HR, skin turgor, mucous membrane, thirst, urine output, and mental status change.
- Oral rehydration therapy is very important in diarrhea treatment.
- Consider intravenous rehydration when oral rehydration fails. Watch out for potassium depletion.
- Early re-feeding decreases recovery time.

Principles of treatment include:

- Rehydration: Orally or intravenously, PRN
- Treatment of symptoms such as fever, abdominal pain, nausea, vomiting as needed
- Identify and treat complications

REHYDRATION:

- Oral hydration products include Naturalyte, Rehydralyte.
- Intravenous solutions used include dextrose 5% in 0.5 isotonic NaCl with 50 mEq $NaHCO_3$ and 10 to 20 mEq KCl.
  1. Indications for IV hydration include intractable vomiting, severe dehydration, change in mental status or consciousness, and ileus.
  2. Oral hydration is not appropriate due to environmental conditions.

TREATMENT OF SYMPTOMS:

- Infectious diarrhea sometimes requires empiric treatment with antibiotics. Foodborne toxigenic diarrhea usually does not.
- Traveler diarrhea: Patients without fever or dysentery may be treated with rifaximin 200 mg thrice daily for 3 days, or ciprofloxacin 500 mg twice daily or 750 mg daily for 1 to 3 days; patients with fever or dysentery can be treated with azithromycin 1000 mg in a single dose.
- *C. difficile* diarrhea and parasitic infestations with *Giardia* or *Entamoeba* are treated with metronidazole or vancomycin. For *C. difficile*, it is important to discontinue the causative antibiotic.
- Treat severe nausea and vomiting with antiemetics.
- Antidiarrheal agents may be useful for systemic relief in mild to moderate diarrhea.
- Loperamide (Imodium) or bismuth subsalicylate (Pepto-Bismol) may provide limited relief in traveler or nonbloody diarrhea.

Dietary measures may include:

- Start with banana, rice, applesauce, toast diet (BRAT diet)
- As early as possible introduce lean meats and clear liquid

In recent yrs the use of probiotics (nonpathogenic live microorganism) has increased; however, recent multicenter trials of combination probiotic (combined *L. rhamnosus-L. helveticus* given twice/day) for children with gastroenteritis did not show any significant benefit and should not be recommended in young children with acute gastroenteritis.[1]

REFERRAL

Referral to infectious disease or gastroenterologist specialist may be indicated in patients:

- With diarrhea lasting more than 7 days
- Hypernatremia
- Severe dehydration associated with cardiovascular symptoms
- In whom a parasitic etiology is suspected
- With *C. difficile* resistant to treatment with metronidazole and vancomycin
- With HIV/AIDS, immunocompromised
- With clinical features indicating extraintestinal involvement (e.g., meningitis, sepsis, pneumonia) or another etiology (e.g., hemolytic uremic syndrome)
- Who relapse

[1]Freedman SB et al: Multicenter trial of a combination probiotic for children with gastroenteritis, *N Engl J Med* 379:2015-26, 2018.

PEARLS AND CONSIDERATIONS

PREVENTION

- Perform proper hand washing before and after eating and after each bowel movement to prevent spread to family members.
- Avoid (raw) shellfish served in certain unregulated places.
- Avoid raw or undercooked eggs and/or poultry.
- Wash all produce before consumption.
- For travelers to high-risk areas:
  1. Eat only cooked foods.
  2. Drink hot or carbonated beverages.
  3. Avoid water, raw peeled fruits/vegetables, green leafy vegetables, and street food sold by street vendors.
  4. Vaccines are available for *Salmonella typhi* and *Vibrio cholerae* (the latter provides about 50% protection for 3 to 6 months).

PATIENT & FAMILY EDUCATION

- Stress the importance of oral rehydration.
- Stress the need for early appropriate feeding.
- Relapse occurs due to dietary noncompliance.
- Travelers to developing areas should be educated on proper avoidance measures and treatment.
- Also stress the importance of good hygiene, hand washing, safe food preparation, and access to clean water as key in preventing gastroenteritis.

BASIC INFORMATION

DEFINITION

Gastroesophageal reflux disease (GERD) is a motility disorder characterized primarily by heartburn and caused by the reflux of gastric contents into the esophagus. A current definition is a condition that develops when the reflux of stomach contents causes at least two heartburn episodes per week and/or complications. Table 1 describes a classification system for esophagitis.

SYNONYMS

Peptic esophagitis
Reflux esophagitis
GERD

ICD-10CM CODES

K21.9 Gastroesophageal reflux disease without esophagitis
R12 Heartburn

EPIDEMIOLOGY & DEMOGRAPHICS

- GERD is one of the most prevalent gastrointestinal disorders. It is the most common GI diagnosis recorded during visits to outpatient clinics. From 14% to 20% of adults are affected.
- Nearly 7% of persons in the United States have heartburn daily, 20% have it monthly, and 60% have it intermittently. Incidence in pregnant women exceeds 80%.
- Nearly 20% of adults use antacids or over-the-counter H_2 blockers at least once a week for relief of heartburn.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination: Generally unremarkable
- Clinical signs and symptoms: Heartburn, dysphagia, sour taste, regurgitation of gastric contents into the mouth
- Chronic cough and bronchospasm
- Chest pain, laryngitis, early satiety, abdominal fullness, and bloating with belching
- Dental erosions in children

TABLE 1 Los Angeles Endoscopic Classification System for Esophagitis

Grade A	One or more mucosal breaks confined to folds, ≤5 mm
Grade B	One or more mucosal breaks >5 mm confined to folds but not continuous between the tops of mucosal folds
Grade C	Mucosal breaks continuous between tops of two or more mucosal folds but not the circumferential
Grade D	Circumferential mucosal break

ETIOLOGY

- Incompetent lower esophageal sphincter (LES) (see Fig. E1)
- Medications that lower LES pressure (calcium channel blockers, alpha-adrenergic antagonists, nitrates, theophylline, anticholinergics, sedatives, prostaglandins).
- Foods that lower LES pressure (chocolate, yellow onions, peppermint). Table 2 summarizes modulators of lower esophageal sphincter (LES) pressure
- Tobacco abuse, alcohol, coffee
- Pregnancy
- Gastric acid hypersecretion
- Hiatal hernia (controversial) present in >70% of patients with GERD; however, most patients with hiatal hernia are asymptomatic
- Obesity is associated with a statistically significant increase in the risk for GERD symptoms, erosive esophagitis, and esophageal carcinoma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer disease
- Unstable angina
- Esophagitis (from infections such as herpes, *Candida*), medication induced (doxycycline, potassium chloride), eosinophilic esophagitis
- Esophageal spasm (nutcracker esophagus)
- Cancer of esophagus

WORKUP

- Aimed at eliminating the conditions noted in the differential diagnosis and documenting the type and extent of tissue damage. Generally, when symptoms of GERD are typical and the patient responds to therapy, there is no need for further diagnostic tests to verify the diagnosis.
- Upper GI endoscopy (Fig. E2) is useful to document the type and extent of tissue damage in persistent GERD and to exclude eosinophilic esophagitis and potentially malignant conditions such as Barrett esophagus. The American College of Physicians recommends endoscopy in the setting of GERD in people with heartburn and alarm symptoms (dysphagia, bleeding, anemia, weight loss, and recurrent vomiting). It is also indicated in people with GERD symptoms that persist despite a therapeutic trial of 4 to 8 wk of bid proton pump inhibitor (PPI) therapy in patients with severe erosive esophagus after a 2-mo course of PPI therapy to assess healing and rule out Barrett esophagus.

LABORATORY TESTS

- 24-hr esophageal pH monitoring with transnasal catheter or a 48-hr wireless capsule are sensitive diagnostic tests to assess the degree of acid exposure in the esophagus in patients not responding to acid-reducing therapy; however, they are not practical and generally not done. They are useful in patients with atypical manifestations of GERD, such as chest pain or chronic cough.
- High-resolution esophageal manometry (HRM) is indicated in patients with refractory reflux in whom surgical therapy is planned.
- *Helicobacter pylori* testing is not indicated in GERD.

IMAGING STUDIES

An upper GI series is useful in patients unwilling to have endoscopy or with medical contraindications to the procedure. It can identify ulcerations and strictures; however, it may

miss mucosal abnormalities. Only one third of patients with GERD have radiographic signs of esophagitis on an upper GI series.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Lifestyle modifications with avoidance of foods (e.g., citrus- and tomato-based products, onions, spicy foods, carbonated beverages, mint, chocolate, fried foods) and drugs that exacerbate reflux (e.g., caffeine, β-blockers, calcium channel blockers, α-adrenergic agonists, theophylline)
- Avoidance of tobacco and alcohol use
- Elevation of head of bed (4 to 8 in) with blocks
- Avoidance of lying down directly after late or large evening meals, consumption of smaller and more frequent meals
- Weight reduction to BMI <25, decreased fat intake
- Avoidance of clothing that is tight around the waist

GENERAL Rx

- PPIs (esomeprazole 40 mg qd, omeprazole 20 mg qd, lansoprazole 30 mg qd, rabeprazole 20 mg qd, or pantoprazole 40 mg qd, or dexlansoprazole 30 mg) are generally safe, tolerated, and highly effective in most patients (Table E3). Omeprazole and esomeprazole are inhibitors of CYP2C19 and can increase serum concentrations of phenytoin and diazepam. Concomitant use of clopidogrel should also be avoided with omeprazole and esomeprazole. Increased risk of pneumonia has been documented in hospitalized patients. Long-term use of PPIs has been associated with increased risk of osteoporosis and patients should be warned about an increased risk of fractures with long-term use. Use of PPIs in patients with cirrhosis increases risk of spontaneous bacterial peritonitis and hepatic encephalopathy. Rare side effects of PPIs include acute interstitial nephritis, hypomagnesemia, and QT prolongation.
- H_2 blockers (nizatidine 300 mg qhs, famotidine 40 mg qhs) can be used but are generally much less effective than PPIs.
- Antacids (may be useful for relief of mild symptoms; however, they are generally ineffective in severe cases of reflux).
- Prokinetic agents (metoclopramide) are indicated only when PPIs are not fully effective. They can be used in combination therapy; however, side effects limit their use.
- Combination of PPE with an agent that reduces esophageal sphincter relaxation (baclofen) plus a neuromodulator (desipramine) may be tried in patients with refractory heartburn before considering surgery.
- For refractory cases: Think first, cut last. Surgery with Nissen fundoplication (Fig. E3). Potential surgical candidates should have reflux esophagitis documented by esophagogastroduodenoscopy and normal esophageal motility as evaluated by manometry. Surgery generally consists of reduction of hiatal hernia when present and placement of a gastric wrap around the gastroesophageal (GE) junction (fundoplication). Although laparoscopic fundoplication is now widely used, long-term medical therapy is a better choice for most patients who are willing to remain on daily acid-reduction medication. In patients preferring surgical intervention, surgery should not be advised with the expectation that patients with GERD will no longer need to take antisecretory medications or that the procedure will prevent esophageal cancer among those with GERD and Barrett esophagus. Approximately 17.7% of patients who undergo primary laparoscopic antireflux surgery will experience recurrent gastroesophageal reflux requiring long-term medication use or secondary antireflux surgery. Risk factors for recurrence are older age, female sex, and comorbidity.
- Endoscopic radiofrequency heating of the GE junction (Stretta procedure) is a treatment modality for GERD patients unresponsive to traditional therapy. Its mechanism of action remains unclear. Endoscopic gastroplasty (EndoCinch procedure) is also aimed at treating GERD. Initial results appear encouraging; however, long-term studies are needed before recommending these procedures. A newer surgical approach to GERD is the LINX antireflux device (Figs. E4 and E5).
- Lifestyle modification must be followed for life because GERD is generally an irreversible condition in most patients.

DISPOSITION

- Recurrence of reflux is common if treatment is discontinued. Preliminary trials have shown that in patients with severe reflux esophagitis successfully treated with PPI therapy, stopping PPI medication was associated with T lymphocyte–predominant esophageal inflammation and basal cell and papillary hyperplasia without loss of surface cells.
- The majority of patients respond well to therapy. In patients with chronic GERD, long-term outcomes are similar between medical therapy with PPIs and anti-reflux surgery. Prolonged use of PPIs is associated with increased risk of fractures of hip, wrist, and spine; increased risk of diarrhea from *Clostridium difficile;* pneumonia; and possible iron deficiency from impaired iron absorption. PPIs also block the effects of clopidogrel by inhibiting cytochrome P450 2C19 isozyme. Therefore all PPIs (other than pantoprazole) should be avoided in patients using clopidogrel. H_2 blockers can be used for patients with GERD taking clopidogrel.
- Postsurgical complications occur in nearly 20% of patients (dysphagia, gas, bloating, diarrhea, nausea). Long-term follow-up studies also reveal that within 3 to 5 yr, 52% of patients who had undergone antireflux surgery are taking antireflux medications again.

REFERRAL

- There is a strong and probably causal relation between symptomatic prolonged and untreated GERD, Barrett esophagus, and esophageal adenocarcinoma. GI referral for upper endoscopy is needed when there are concerns about associated peptic ulcer disease, Barrett esophagus, or esophageal cancer.
- Patients with Barrett esophagus should undergo surveillance endoscopy with mucosal biopsy every 2 yr or less because the risk of developing adenocarcinoma of esophagus is at least 30 times greater than that of the general population.
- Testing and treating for *Helicobacter pylori* in patients with GERD has not been shown to improve symptoms.
- All children with dental erosions should be evaluated for GERD.

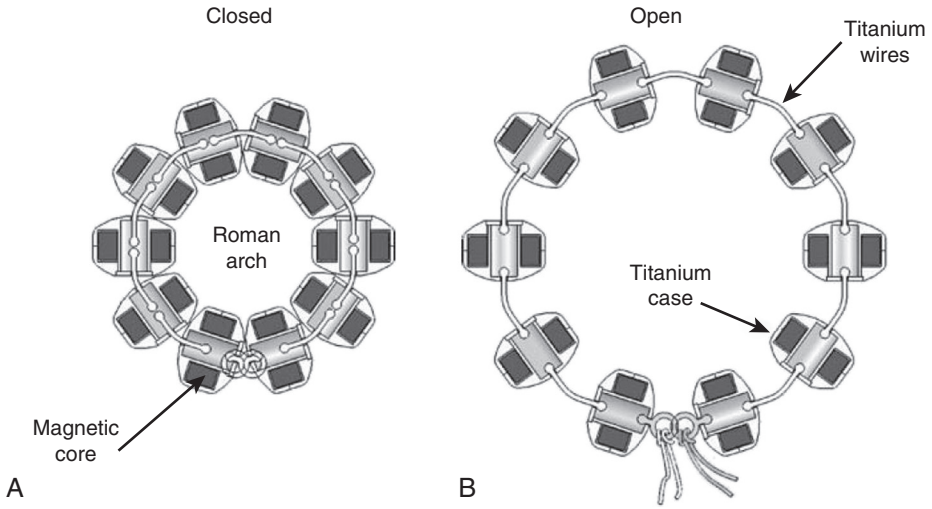

FIG. E4 An engineering schematic of the magnetic sphincter augmentation device. The device consists of an expansible bracelet of magnetic beads designed to be placed surgically around the exterior surface of the distal end of the lower esophageal sphincter (LES). Each bead is composed of a titanium case containing a magnetic core of small, disk-shaped magnets. The beads are connected by titanium wires of specific lengths that limit the distance any two individual beads can move apart. When the device is closed **(A),** the magnetic force is sufficient to prevent effacement and opening of the LES yet is weak enough to allow the device to open **(B)** with the esophageal peristalsis. When the device is closed, the Roman arch construction prevents compression of the esophageal tissues. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.)

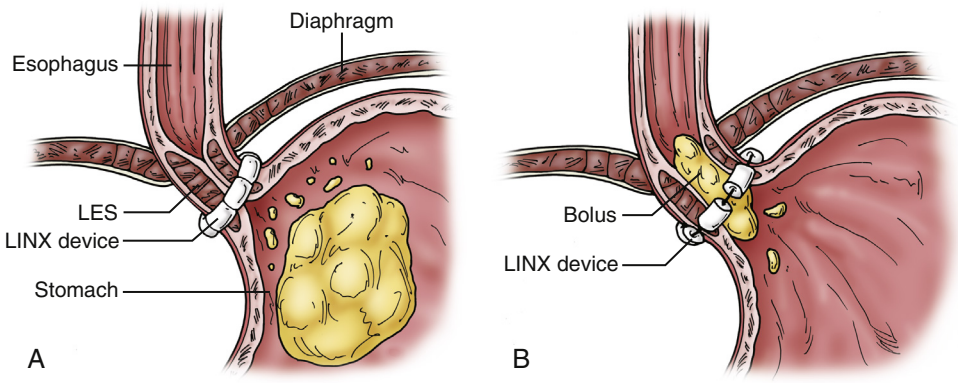

FIG. E5 The LINX magnetic sphincter augmentation device is implanted around the inferior border of the lower esophageal sphincter *(LES)* as shown. A, The magnetic device in the closed position, which prevents effacement and opening of the LES and subsequent reflux. Each magnetic bead rests on the adjacent beads to prevent compression of the esophageal tissues. **B,** The device in the open position, which allows transport of food by esophageal peristalsis, belching of an overdistended stomach, and vomiting when necessary. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.)

Gender Dysphoria and Gender Nonconformity

BASIC INFORMATION

DEFINITION

Transgender or *gender diverse (TGD) identity* is an umbrella term when a person's perceived and innate sense of being male or female (i.e., gender identity) is at odds with the natal assigned gender based on chromosomes, hormones, organs, and eventually secondary sexual characteristics. For some TGD persons, gender dysphoria may result when an individual's gender identity is incongruent with the person's assigned gender, with discomfort and dislike of one's external gender characteristics and a desire to be physically different from the gender born into or assigned at birth. Other TGD persons may not experience dysphoria or distress but understand their gender in a way that varies from a male-female binary. Transition is a social, medical, and surgical process, whereby TGD persons present in the gender with which they identify. Transition is typically divided into three types (reversible, partially reversible, and irreversible), but should be tailored to the individual throughout the life span while also providing comprehensive medical care.

SYNONYMS

Gender dysphoria/gender incongruence
GD/GI
TGD
Transgender–Gender diverse; gender dysphoria in children, adolescents, adults
Transgender-gender diverse identity
Transsexual

ICD-10CM CODES
For the purposes of medical care for transgender individuals, ICD-10 codes are already inaccurate and do not represent and reflect current standards and understanding of gender development. The diagnostic entity of gender identity disorder has been rejected as pathologizing and inappropriate per DSM-5 psychiatric coding.

F64.0	Transsexualism
F64.2	Gender identity disorder of childhood
F64.9	Gender identity disorder, unspecified
F64.8	Other gender identity disorder
E34.9	Endocrine, Hormones Disease of, Disorder(s), Dysfunction(s), Disturbance, Complication(s) from

DSM-5: See note above regarding DSM-5.

EPIDEMIOLOGY & DEMOGRAPHICS

DEVELOPMENT & BACKGROUND: Gender development begins as early as 18 mo. By age 2 to 4 yr, children understand gender differences and use pronouns such as "him" and "her." Toddlers identify their own gender, and most consider gender a stable personal trait at age 5 to 6 yr. All children partake in gender play and explore gender activities, behaviors, and roles. Gender play does not mean a child is dysphoric, dislikes his or her gender, or identifies as the other gender. Gender diversity in prepubertal yrs is more than gender play; nonconforming prepubertal children exhibit *consistent, persistent, and insistent* play, dress, attributes, and activities of the other gender. Some of these children, but not all, experience dysphoria regarding their genitalia or express mild to intense discomfort and dislike of their biologic gender. Some, but not all, gender nonconforming prepubertal children may verbally assert that they are or need to be the other gender. Some TGD children, adolescents, and adults have more fluid interpretations of gender and do not easily fit into a masculine versus feminine binary. As we talk more with patients, we learn more and more about the inherent diversity of gender.

PREDOMINANT AGE: Incidence may be heavily associated with cultural expectations. It is generally less acceptable to be a feminized boy than a prepubertal girl who is a "tomboy." At puberty there appears to be a spike in gender dysphoria, with the onset of discordant secondary gender characteristics.

PREVALENCE: Overall, it is estimated that 0.6% of people identify as transgender, or approximately 1.4 million U.S. citizens per the 2016 CDC-based Behavioral Risk Factor Surveillance System and the UCLA School of Law Williams Institute. Accurate data are absent and likely underestimate prevalence. Additionally, it appears that younger age and geography are associated with increased TGD representation.

GENETICS: There is no known single or specific genetic basis for TGD identity or gender dysphoria. There appear to be no specific relationships between transgender identity with socioeconomic status, race, or ethnicity. TGD identity may be more common in those with autistic spectrum disorders.

RISK FACTORS: Most children and adults benefit from medical care and social systems that do not pathologize their innate sense and experience of self. However, children and teens who are TGD have historically experienced higher rates of child abuse, bullying, mental health concerns (e.g., anxiety, depression, suicidality, eating disorders), and substance use. Historically, transgender adult populations have poorer health outcomes, such as depression, anxiety, self-harm and suicide, substance use, underemployment, homelessness, incarceration, and positive HIV status. Poorer health outcomes are explained by using minority stress theory (chronic stress related to stigma and dysphoria) rather than gender variance as a pathology itself.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

TGD prepubertal children may present with *consistent, persistent, and insistent* interest and expression of other or opposite-gendered activities and behaviors, or they may present with a more gender-fluid identity. Many gender dysphoric children may initially present with more normative gender play and expression, however, still experience underlying problems with their internal gender identity.

Adolescents and adults may present clinically at any point along the life span, though many express having cross-gender feelings and identities earlier in life. For some patients, the physical changes of puberty become an unbearable reminder of internal vs. external gender dissonance. Research suggests that when gender dysphoria is increased by the onset of puberty it rarely subsides. Some gender dysphoric persons will not present initially with gender dysphoria but with mood, behavior, or social problems.

DIAGNOSIS

- TGD identity is not considered pathologic or requiring psychiatric evaluation and care. Developmental models instead view gender along a biologic spectrum with diverse presentations and expression. Persons may assert TGD identity without severe self-hatred or significant dysphoric presentation. Psychiatric evaluations are no longer required or essential to "diagnose" gender nonconforming persons; however, mental health and social work services may help support individuals or their families in their transition plan.
- Changes in DSM-5 focus on "gender dysphoria" and inherent distress in one's natal gender and biologic gender characteristics reflecting a shift from a "disorder" of identity. For an individual to be diagnosed with gender dysphoria, marked differences between the individual's natal or assigned gender and expressed/experienced gender must exist for at least 6 mo; cause clinically significant distress or impairment in social, occupational, or other important areas of functioning; with strong and consistent desire to be the other gender.

WORKUP

- Ideally, this assessment begins with interviewing the individual as a part of a holistic health assessment. Persons with various degrees and experience in behavioral health can perform these interviews. Mental health and social support may help patients cope with body dysphoria, treat comorbid mental health concerns, assist with social and emotional skill building, and create a safe and successful transition plan. Parents of a TGD child may benefit from counseling services so that they may address their own parental reactions to transition and successfully focus on the child's issues and needs. Consistently, research demonstrates that early family support of a child's authentic gender identity is linked to positive mental health outcomes.
- Clinical interview includes assessment of gender experience from childhood until present; desired name, pronouns, and past and current place on the gender spectrum; past and current attempts to feminize or masculinize with clothing, hair, makeup, hormones (both prescribed and nonprescribed), and surgeries; future goals of transitioning,

gender identity, and expression. Transition goals, gender identity, and expression will vary among each individual and may not fit into traditional binaries. For many children, parents may provide insight as to early childhood gender identity and expression. For some children, parental distress and denial of a consistent cross-gender identity is the most problematic aspect of providing care.

- Review for known comorbidities by asking mental health specific questions about: depression, anxiety, eating disorders, self-harm (cutting, suicidal ideation, suicide attempts), psychiatric hospitalization, and substance use. Patient history should also include: sexual attraction and behaviors and risk for sexually transmitted infections and pregnancy; social history, experience of bullying, hate crimes, physical or emotional/verbal abuse, homelessness, joblessness, and survival sex. Resiliency theory also promotes focusing on patient strengths and identifying social support systems.
- An initial visit may include a physical examination, depending on the provider and patient goals. Many gender dysphoric persons are exquisitely uncomfortable with their genitalia and genital examination. If the evaluation is a consultation for information and counseling, an exam may be deferred until the patient is more comfortable and familiar with the provider. Tanner staging of genitalia, along with hormonal measures, can estimate pubertal stage and appropriateness for puberty blockers or gender-affirming hormones.
- Luteinizing hormone is a preferred lab for evaluating prepubertal children and Gonadotropin releasing hormone (GnRH) analogue use, but additional laboratory studies may include follicle stimulating hormone, testosterone, or estradiol. For older youth or adults starting gender affirming hormones (GAH), baseline laboratory values may include CBC, lipid panel, and liver function tests. GAH may affect hematopoiesis, cholesterol levels, and irritate the liver. More recent data suggest that extensive laboratory testing is likely unnecessary for most patients, as there do not seem to be clinically significant changes in these laboratory values over time. Testosterone may be useful to measure androgen suppression in asserted women receiving estrogen therapy or in asserted men aiming for physiologic male levels. Evaluating levels of estradiol or testosterone may be useful only if clinical goals are not being achieved. Potassium and blood pressure monitoring is useful in transwomen starting spironolactone to block male pattern hair growth.
- Screening for sexually transmitted infections (urine, rectal, and oral *Chlamydia* and gonorrhea; syphilis; herpes simplex virus; HIV; hepatitis B and C), and pregnancy is indicated according to sexual practices. Transwomen, including transwomen of color, have some of the highest rates of HIV; consider offering pre-exposure prophylaxis for HIV (PREP) if consistent with sexual practices.
- Attention to regular routine health needs (vaccines, lab work, and screenings) should be addressed in all TGD individuals. Over time, patients should receive typical preventive and screening tests for both natal and asserted gender in accordance with what hormones and anatomy are present.

Rx TREATMENT

Treatment recommendations are flexible and should be individualized to the specific goals expressed by the patient. Treatment is determined by patient age and development (including Tanner stage) and desired place on the gender spectrum. A diagnosis of gender dysphoria/gender incongruence (GD/GI) should be confirmed before proceeding with gender-affirming hormone therapy.

REVERSIBLE TRANSITION

- Social transition includes taking a name and pronouns in the identified gender, as well as clothing, shoes, hair, make-up, and other gender identifying social cues. For prepubertal, androgynous children, social transition does not require hormones, but does require extensive planning for disclosure, social support, and peer- and school-based activities Timing for social transition varies, but many individuals are beginning the social transition process long before medical therapies.
- GnRH agonists act to block the hypothalamic pituitary gonadal axis and put a "pause" on endogenous gender hormone secretion. Puberty blockers are completely reversible and best when used at very early Tanner stage II breast and testicular development. When used in early puberty, blockers stop puberty and permit regression to prepubertal hormone levels to allow a patient to remain at his or her current androgynous physical gender characteristics. Stopping puberty "buys time" for the patient and family to explore their gender goals and to determine safe and healthy next steps.
- GnRH analogues may be used for patients who are later in puberty (Tanner 3-5 genital exam) but who are still androgynous in regard to secondary gender characteristics, such as voice, facial and body hair, bone, muscle, and fat deposition. Blockers can also be used to stop erectile function or menses, which can be highly distressing to some gender dysphoric persons.
- GnRH analogues are *completely reversible.* If stopped, a person can continue into biologic puberty with no impact on future gender characteristics or fertility.
- Most teens who opt to start GnRH agonists to block puberty continue to create a transition plan and eventually move to GAH and puberty in their asserted gender. The current literature from the past 30 or more yrs demonstrates that it is unlikely that an adolescent who is consistently, persistently, and insistently gender nonconforming or transgender will return to his or her assigned natal gender or regret either blockers or GAH. This can be both of concern and relief to parents as they determine how to best to support their child.

PARTIALLY REVERSIBLE TRANSITION:

- GAH therapies include testosterone for masculinization and estradiol for feminization. Both hormones may have reversible effects on skin, fat deposition, and muscle mass. Irreversible testosterone effects may include lower voice, male pattern face and body hair, and clitoromegaly. Irreversible estradiol effects include areolar enlargement and breast tissue growth. These changes are usually desired by transgender individuals and desired for continued transition into their asserted gender. It is also important to address the limitations of GAH.
- Estradiol creates softer skin, female body fat deposition (hips/thighs), and breast development. It may impair erectile function, which may or may not be desired because some male-to-female persons still want or depend on penile function (masturbation, sexual relationships, and/or sex work). Estradiol is typically administered sublingually but can be taken intramuscularly, orally, or topically.
- Testosterone masculinizes by deepening the voice and inducing male-pattern hair, fat, and muscle deposition (bulk and abdominal girth) and clitoromegaly.
- Both gender hormones should not be used in lieu of contraception, as current evidence suggests that estrogen or testosterone is not sufficiently effective as a contraceptive. Persons taking testosterone who are having unprotected egg–sperm sex should be counseled about the chance of pregnancy and offered birth control in addition to testosterone. Alternatively, fertility may be impaired, and individuals who feel strongly about having future genetic children or childbearing may wish to consult reproductive endocrinology and infertility specialists to discuss sperm- and oocyte-preservation strategies before initiating GAH.
- Consent to what we know and do not know is an important part of beginning the cross-gender hormone process. We currently do not have strong guidelines or outcome studies for ongoing preventive care and anticipatory guidance.

IRREVERSIBLE TRANSITION: The U.S. Department of Health and Human Services Departmental Appeals Board ruled Medicare's categorical exclusion of gender confirmation medical and surgical treatments was unreasonable and contrary to medical standards of care. Several states have adopted legislation that should prevent insurers from excluding transgender care services; however, there is as yet no consensus or plan for universal coverage for transgender health services.

Surgical options for masculinization include mastectomy and male chest reconstruction, hystero-oophorectomy, and orchi-penoplasty; for feminization they include orchiectomy-penectomy with vulvovaginal reconstruction, breast implants, and other cosmetic surgeries.

Some patients do not want surgery, while others opt for partial surgical transition.

ADDITIONAL THERAPIES: Antiandrogens such as spironolactone or finasteride prevent male-pattern hair growth, while laser treatment and electrolysis offer permanent hair removal. Female patients may desire vocal coaching, tracheal shaving, and facial feminizing surgeries. Progesterone may promote increased breast development, although there is no evidence pointing to effectiveness or risk. Topical androgen therapies do not seem to improve clitoral growth.

Individual, family, and marital counseling and therapies can be important, as can psychiatric medications for comorbid conditions as persons and families negotiate the process of transition. Reparative therapy is *universally* rejected as *unethical and harmful* by all the national medical and psychological boards and associations.

DISPOSITION

- Younger prepubertal gender nonconforming patients may grow up and be cisgender or transgender, hetero or homosexual. Patients who have early consistent, persistent, insistent dysphoria or cross-gender identification are more likely to continue this into puberty and eventually transition. There is also a growing population of gender-fluid patients who do not easily fit into dichotomous gender binaries.
- "Passing" in one's asserted gender can have significant and demonstrated protective effects for victimization from hate crimes and interpersonal violence, low socioeconomic status, underemployment, and isolation. Early identification and early transition in a person's identified gender, along with a better likelihood of acceptance, offers significant psychosocial benefits to many gender dysphoric persons.

REFERRALS

There are few contraindications to transitioning for most transgender or gender dysphoric persons. Active psychosis and inability to consent to care would require further psychiatric evaluation but are extremely rare. For older persons, some medical issues involving cardiac, liver, and thromboembolic risks complicate hormone use and need to be taken into consideration.

PEARLS & CONSIDERATIONS

- Periodic assessment of a person's place on the gender spectrum can begin in toddler age children and can continue into adulthood as a potentially effective way of helping identify and support TGD or gender dysphoric persons earlier. Earlier identification and parental support for gender dysphoric and TGD persons may lead to improved mental and physical health outcomes.
- Hormone blockers and GAH typically offer far more benefit than risk in the treatment of gender dysphoria when a person desires to transition to the opposite gender.
- Affirming treatment of TGD-identified persons will vary depending on patient-specific goals and gender expression. Treatment should be individualized but also comprehensive, including appropriate screening and preventative tests, social and legal support, and mental health resources.
- Federal and state changes in mandated insurer coverage of gender care, including gender affirming surgeries, may offer substantial benefit for a growing population of transgender identified persons.

PATIENT & FAMILY EDUCATION

- The World Professional Association for Transgender Health promotes the highest standards of health care for individuals through the articulation of Standards of Care (SOC) for the Health of Transsexual, Transgender, and Gender Nonconforming People. The SOC are based on the best available science and expert professional consensus: www.wpath.org/publications/soc
- Center of Excellence for Transgender Health, the mission of which is to increase access to comprehensive, effective, and affirming health care services for trans communities: http://transhealth.ucsf.edu/
- The Trans Health Program at Fenway helps to ensure access to high-quality, informed care for trans women, trans men, genderqueer, gender nonconforming, nonbinary individuals, affirmed men and women, people with trans histories, and anyone with health needs unique to their diverse gender expressions and identities: http://fenwayhealth.org/care/medical/transgender-health/

BASIC INFORMATION

DEFINITION

Genitopelvic pain/penetration disorder, previously referred to as the separate conditions of "vaginismus" or "dyspareunia," is described in DSM-5 as encompassing persistent or recurrent difficulty in having intercourse, marked vulvovaginal or pelvic pain associated with attempts at intercourse, marked fear or anxiety associated with the pain of intercourse, or tensing or tightening the pelvic floor muscles while attempting vaginal intercourse. Symptoms must have persisted for a minimum of 6 mo and cause clinically significant distress to the individual. The condition may be lifelong or acquired.

SYNONYMS

Vaginismus
Dyspareunia

ICD-10CM CODES

N94.1	Unspecified dyspareunia
N94.2	Vaginismus
F52.5	Vaginismus not due to a substance or known physiological condition
F52.6	Dyspareunia not due to a substance or known physiological condition

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Estimated at 11.7% to 42% of women presenting to sexual dysfunction clinics
PREVALENCE: Affects 14% to 34% of younger women and 6.5% to 45% of older women
PREDOMINANT SEX: Affects people with vulvas
RISK FACTORS: Any previous sexual trauma, including incest or rape

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Tightening of the vaginal muscle with decreased ability or inability to accommodate penetration
- Tension, pain, or burning felt when penetration is attempted
- Decrease in or no desire to have intercourse
- Avoidance of sexual activity
- Intense phobia or fear of pain

ETIOLOGY

- Learned conditioned response (Fig. E1) to real or imagined painful vaginal experience (e.g., traumatic speculum examination, incest, rape)
- Vaginitis
- Pelvic inflammatory disease
- Endometriosis
- Anatomic anomalies
- Atrophic vaginitis
- Mucosal tears
- Inadequate lubrication
- Focal vulvitis
- Painful hymenal tags
- Scarring secondary to episiotomy
- Skin disorders
- Topical allergies
- Postherpetic neuralgia

DIAGNOSIS

WORKUP

- Thorough history (including sexual and psychological history)
- Careful pelvic examination

TREATMENT

An individualized, multidisciplinary approach must be taken to treat the underlying and exacerbating physical and emotional aspects of this condition.

NONPHARMACOLOGIC THERAPY

- Pelvic floor physical therapy, including deconditioning the response by systematic self-administered progressive dilation techniques using fingers or dilators
- Behavioral and/or psychosexual therapy

PHARMACOLOGIC THERAPY

- Intravaginal prasterone, low-dose vaginal estrogen, and ospemifene can be used in postmenopausal women
- Lubricants, topical anesthesia, and moisturizers may help reduce or alleviate dyspareunia

ACUTE GENERAL Rx

- Cause should be determined by history and explained to the patient so that she understands the possible mechanics of this disorder.
- Patient must be motivated to desire painless vaginal insertion for such reasons as pleasurable coitus, tampon insertion, or gynecologic examination.
- Patient (and her partner) must be willing to patiently undergo the process of systematic desensitization and counseling.

DISPOSITION

A high percentage of successfully treated patients

REFERRAL

To a gynecologist or sex therapist

BASIC INFORMATION

DEFINITION

Genitourinary syndrome of menopause (GSM) is a collection of chronic, progressive symptoms and signs related to menopause, which include changes to vulvovaginal and bladder-urethral areas due to a decrease in estrogen and other sex steroids. The symptoms and signs include vaginal dryness, burning, soreness, and irritation; sexual symptoms of lack of lubrication, discomfort or pain, and impaired function; and urinary symptoms of frequency, urgency, urge incontinence, and recurrent urinary tract infection.

SYNONYMS

Vulvovaginal atrophy (VVA)
Atrophic vaginitis
Urogenital atrophy
GSM

ICD-10CM CODES

N95.1	Menopausal and female climacteric states
N95.2	Postmenopausal atrophic vaginitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: GSM can occur at any time in a woman's life; however, it is more common during the postmenopausal phase, affecting >50% of women at this age versus ~15% of premenopausal women.

PREVALENCE: According to a cross-sectional population-based study, GSM and its features affect 57% of sexually active women in the United States aged 40 to 65 yr.

RISK FACTORS:

- Menopause
- Nonmenopause hypoestrogenism
- Bilateral oophorectomy
- Cigarette smoking
- Alcohol abuse
- Decreased sexual frequency and abstinence
- Ovarian failure
- Lack of exercise
- Absence of vaginal childbirth
- Estrogen deficient because of cancer treatments

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Principal symptoms include vaginal dryness, dyspareunia, burning, itching, and dysuria.
- Atrophy of the labia majora and vaginal introitus are observed, include labial thinning, narrowing of the introitus, decreased width and depth of the vagina, along with observed pale and dry vulvar and vaginal tissues with loss of rugae and elasticity.
- Laboratory studies may suggest an increase in vaginal pH (>5.0) with loss of superficial cells on vaginal maturation index.
- A thin, watery, yellowish vaginal discharge may be noticed. A urethral caruncle may develop.
- GSM symptoms are also reported to negatively affect sexual satisfaction in >50% of patients, as well as in their personal relationships.

ETIOLOGY

- The etiology of GSM is secondary to hypoestrogenism, which is predominantly caused by decreased levels of endogenous estrogen during the transition between perimenopausal and postmenopausal yr in the female body.
- Other etiologies of hypoestrogenism include postpartum and lactation, use of medications with antiestrogenic effects, bilateral oophorectomy, hypothalamic amenorrhea or amenorrhea combined with glucocorticoid therapy, primary ovarian insufficiency, breast cancer treatments including chemotherapy, pelvic surgery, radiation, and aromatase inhibitors (AIs).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vaginal infections, including *Candida* vulvovaginitis, bacterial vaginosis, trichomoniasis, and desquamative inflammatory vaginitis
- Irritant dermatitis in response to perfumes, deodorants, soaps, lubricants, spermicides, perineal pads, or panty liners
- Vulvovaginal dermatoses, including lichen sclerosus, lichen planus, and lichen simplex chronicus
- Cancer and precancerous lesions, including vulvar intraepithelial neoplasm, vulvar cancer, and extramammary Paget disease
- Vulvodynia
- Other etiologies of frequent urinary tract infection or associated symptoms

WORKUP

- Complete medical history focusing on use of medications with antiestrogenic effects and cancer treatments, which include chemotherapy, pelvic surgery, and radiation therapy
- Pelvic examination: Changes in shape and color in external labia majora and minora; atrophy in clitoral hood and the clitoris; changes in vulvar and vaginal tissue; some patients may also experience inflammation with potential vaginal bleeding
- Laboratory testing (see "Laboratory Tests")

LABORATORY TESTS

- Vaginal pH may reach above 4.6 in the absence of other causes.
- Vaginal maturation index (VMI): Microscopic findings on a smear of the vaginal epithelium may include increase of parabasal cells with a significant decrease of intermediate and superficial cells (<5%).

TREATMENT

SYSTEMIC HORMONE THERAPY: Use of estrogen only or estrogen plus progestogen for the management of vulvovaginal symptoms. Systemic hormone therapy is preferred if vasomotor symptoms are also present and require treatment. This therapy is usually combined with other types of treatments.

LOCAL ESTROGEN TREATMENT: Local vaginal estrogen treatment is suggested as the main treatment for GSM, combined with nonhormonal lubricants and vaginal moisturizers. This treatment can work as short-term therapy in improving vulvovaginal symptoms and lower urinary tract symptoms. Treatment options include estrogen creams, vaginal rings, estrogen tablets, vaginal inserts, and intravaginal dehydroepiandrosterone (DHEA). Vaginal estrogen products with suggested low dosage have been U.S. Food and Drug Administration (FDA) approved in the U.S. for the treatment of GSM (Table 1).

SELECTIVE ESTROGEN RECEPTOR MODULATORS (SERMS): Certain SERMs with estrogen agonistic effect have shown improvement in VMI, vaginal pH, vaginal dryness, and dyspareunia (e.g., daily use of ospemifene 60 mg orally).

BAZEDOXIFENE (BZA) AND CONJUGATED ESTROGENS (CES): BZA (20 mg) combined with CE (0.45 or 0.625 mg) has shown significant improvement in vasomotor and vulvovaginal symptoms and dyspareunia, while preventing bone loss and being safe for the endometrium and breast.

NONPHARMACOLOGIC THERAPY

NONHORMONAL TREATMENT: Vulvovaginal symptoms can be improved by use of nonhormonal lubricants during intercourse and regular use of long-acting vaginal moisturizers.

FRACTIONAL CO_2 LASER TREATMENT: Fractional CO_2 laser treatment has been reported in an Australian study to be significantly effective in improving sexual function, relieving symptoms of dyspareunia, and delivering positive changes in bladder function and prolapse symptoms in the long-term (12 to 24 months). However, the laser or energy-based devices have not been approved by the FDA for the treatment of vulvovaginal symptoms.

ACUTE GENERAL Rx

Ospemifene (daily 60 mg orally)

CHRONIC Rx

Vaginal estrogen with prescribed dose (Table 1)

COMPLEMENTARY & ALTERNATIVE MEDICINE

Vaginal hyaluronic acid–based moisturizers are reported to improve vulvovaginal symptoms as effectively as estrogen-based treatment.

REFERRAL

- Postcoital bleeding should be evaluated for cervical cancer.
- Systemic disease (e.g., Crohn disease) consultation if genital tract ulcers or fissures

TABLE 1 Hormonal Therapy for Treatment of Genitourinary Syndrome of Menopause

Treatment	Product	Dosage		Comments
		Initial	Maintenance	
Vaginal Cream				
Estradiol-17b	Estrace (Allergan, Irvine, CA)	0.5-1.0 g, daily for 2 wk	0.5-1.0 g, 1-3 times weekly	FDA-approved dose is higher (loading dose = 2.0-4.0 g, daily; maintenance dose = 1.0 g, 1-3 times weekly)
Conjugated estrogens	Premarin (Pfizer, New York, NY)	0.5-1.0 g, daily for 2 wk	0.5-1.0 g, 1-3 times weekly	FDA-approved dose is higher and administration is cyclic (for GSM, 0.5-2.0 g, daily for 21 days and then off for 7 days; for dyspareunia, [A] 0.5 g, daily for 21 days and then off for 7 days, or [B] 0.5 g, twice weekly)
Vaginal Insert				
Estradiol hemihydrate	Vagifem (Novo Nordisk, Bagsværd, Denmark), Yuvafem (Amneal, Bridgewater, NJ)	10-mcg insert, once daily for 2 wk	1 twice weekly	—
Estradiol-17b softgel capsules	TX-004HR	4, 10, or 25 mcg, daily for 2 wk	1 twice weekly	This product is not yet FDA approved
DHEA (prasterone)	Intrarosa (AMAG Pharmaceuticals, Waltham, MA)	6.5 mg, once daily	6.5 mg, once daily	—
Vaginal Ring				
Estradiol-17b	Estring (Pfizer, New York, NY)	Insert for 90 days (2-mg releases approximately 7.5 mcg daily)	Change every 90 days	—
Estradiol acetate	Femring (Warner Chilcott UK Limited, Larne, Northern Ireland, UK)	Insert for 90 days (12.4-mg or 24.8-mg releases 0.05 mg or 0.1 mg daily, respectively)	Change every 90 days	This product is delivered vaginally but it provides systemic hormone levels to treat VMS and GSM
Selective Estrogen Receptor Modulator				
Ospemifene	Osphena (Duchesnay USA, Rosemont, PA)	60 mg, daily	60 mg, daily	FDA approved for dyspareunia

FDA, U.S. Food and Drug Administration; *VMS,* vasomotor symptoms.
From Faubion SS et al: Genitourinary syndrome of menopause: management strategies for the clinician, *Mayo Clin Proc* 92:1842-1849, 2017.

are detected combined with abdominal pain, blood in stool, and unexplained weight loss.
- Recurrent urinary tract infection with other associated symptoms may require genitourinary workup and/or cystoscopy.

PEARLS & CONSIDERATIONS

COMMENTS

- The estradiol ring may dislodge with bowel movement, sexual intercourse, douching, or Valsalva maneuvers. Vaginal ring users are encouraged to remove or replace the vaginal ring on their own.
- The safety of systemic hormone therapy in women with breast cancer should be carefully considered.
- With the use of local estrogen cream, dosing at least 12 hours before vaginal sexual activity is recommended to prevent estrogen absorption by a sexual partner.

PATIENT & FAMILY EDUCATION

Clinicians should discuss the concept of maintaining sexual function for postmenopausal women. For women with a sexual partner, regular vaginal intercourse or stimulation helps to maintain vaginal health, as well as provide comfort and satisfaction during sexual activities in the future. For women without a sexual partner, regular use of vaginal vibrator or other stimulators should be recommended to maintain healthy vaginal function.

BASIC INFORMATION

DEFINITION

Gestational diabetes mellitus is hyperglycemia occurring during the second or third trimester in absence of a prepregnancy diagnosis of type 1 or type 2 diabetes.

Screening for gestational diabetes mellitus in asymptomatic pregnant women after 24 weeks' gestation is a grade B recommendation by the U.S. Preventive Services Task Force (USPSTF). In the U.S., a two-step approach to screening is commonly used and is currently endorsed by the American College of Obstetricians and Gynecologists (ACOG) and the National Institutes of Health (NIH). The International Association of Diabetes in Pregnancy Study Group has recommended a simplified one-step approach for screening and diagnosing GDM, which has been endorsed by the American Diabetes Association since 2011, with the acknowledgment that the one-step approach increases the prevalence of GDM without clear evidence of benefit. Pregnant women with diabetes mellitus (DM) (gestational or preexisting) are classified according to White classification (Table 1).

SYNONYMS

Gestational diabetes
Diet-controlled gestational diabetes (A1)
Medication-treated gestational diabetes (A2)

ICD-10CM CODES

O24.410	Gestational diabetes mellitus in pregnancy, diet controlled
O24.414	Gestational diabetes mellitus in pregnancy, insulin controlled
O24.419	Gestational diabetes mellitus in pregnancy, unspecified control
O99.810	Abnormal glucose complicating pregnancy

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Approximately 5% of pregnant women in the U.S. will be diagnosed with GDM using the two-step approach and 18% using the one-step approach.

PREDOMINANT SEX AND AGE: Women of childbearing age; increased risk is observed in women over the age of 35 yr.

GENETICS: Higher rate in women with a family history of GDM or type 2 diabetes in a first-degree relative; specific HLA alleles (DR3 or DR4) predispose to the development of DM type 2 after pregnancy.

RISK FACTORS

- Overweight or obesity
- Family history of GDM or type 2 diabetes, particularly in first-degree relatives
- Polycystic ovarian syndrome
- Multiple gestation
- Hypertensive disorder of pregnancy or chronic hypertension
- Chronic systemic steroid use
- History of macrosomia in prior pregnancy
- Personal history of abnormal glucose tolerance or GDM in previous pregnancy
- Hispanic, Native American, African American, Asian, or Pacific Islander ethnicity
- Advanced maternal age (over age 25)
- Unexplained perinatal loss or malformation in previous or current pregnancy may be suggestive of preexisting diabetes

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Suspect GDM if:

- Fetal size greater than dates on Leopold or increased fundal height measurement
- Ultrasound findings of fetal macrosomia (especially enlarged abdominal circumference) or polyhydramnios
- Marked maternal obesity or weight gain above expected range
- Acanthosis nigricans (as underlying insulin resistance increases risk)
- Symptoms of diabetes
- Glucosuria
- Hemoglobin A1C greater than or equal to 5.7 in the first trimester

ETIOLOGY

During normal pregnancy several mechanisms contribute to increased insulin resistance. Placental secretion of human placental lactogen (hPL) decreases maternal insulin sensitivity, decreases maternal glucose utilization, and increases lipolysis, all to ensure adequate glucose availability to the growing fetus. Maternal pancreatic beta cells are increased in order to secrete additional insulin to compensate for the increased circulating blood glucose. Insulin resistance is also exacerbated by an increase in maternal adipose deposition, decreased exercise, and increased caloric intake. GDM occurs when maternal insulin secretion cannot meet the increased glucose burden, resulting in carbohydrate intolerance and hyperglycemia.

TABLE 1 White Classification for Pregnant Women with Diabetes (Gestational or Preexisting)

Class	Description
A1	DM diagnosed during pregnancy and controlled by diet
A2	DM diagnosed during pregnancy and requiring medication
B	Insulin-requiring DM diagnosed before pregnancy, age >20 yr, lasting <10 yr
C	Insulin-requiring DM, onset at age 10 to 19 yr, with a duration 10 to 19 yr
D	Onset >10 yr or duration >20 yr, or associated with hypertension or background retinopathy
F	DM with renal disease
H	DM with coronary artery disease
R	DM with proliferative retinopathy
T	DM with renal transplant

DM, Diabetes mellitus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Preexisting type 1 or 2 DM not previously diagnosed

WORKUP

- History with focus on personal medical history, prior pregnancy history, and family history
- Routine prenatal examination
- Laboratory evaluation (see the following)

LABORATORY TESTS

- Exclude preexisting diabetes
- For women with risk factors (see above), order a 1-hr glucose tolerance test at the first prenatal visit, then repeat at 24 to 28 weeks if initial screen was normal. If abnormal at intake, consider the probability of undiagnosed preexisting DM or underlying insulin resistance and check hemoglobin A1c. A diagnosis of diabetes is made if a woman meets any of the following criteria: Fasting plasma glucose >126 mg/dl, A1c >6.5%, random plasma glucose >200 mg/dl. The authors consider a first-trimester A1c of ≥5.7 suggestive of preexisting insulin resistance, and would be inclined to monitor closely for hyperglycemia.
- Two-step approach:
  1. For screening without risk factors, a 1-hr, nonfasting 50-g oral glucose tolerance test (OGTT) is appropriate. If the result is abnormal (≥130 mg/dl, as defined by Carpenter and Coustan), a 3-hr, 100-g oral glucose tolerance test is performed. The diagnosis of GDM is made if two or more of the following glucose values are met or exceeded:
     a. Fasting: 95 mg/dl
     b. 1-hr plasma glucose: 180 mg/dl
     c. 2-hr plasma glucose: 155 mg/dl
     d. 3-hr plasma glucose: 140 mg/dl
  2. If one of four values on 3-hr glucose tolerance test is abnormal, consider repeat testing in 1 month and recommend a low-carbohydrate diet immediately and consultation with a nutritionist. At least one study has demonstrated increased perinatal risk in women with only one of four abnormal values on 3-hr OGTT
- One-step approach:
  1. Like the two-step, a one-step screening is performed at 24 to 28 weeks on all pregnant patients who have not already been diagnosed with diabetes. This is a 2-hr, 75-g oral glucose tolerance test performed after an overnight, 8-hr fast. A diagnosis of GDM is made if one or more of the following values are met or exceeded:

   a. Fasting: ≥92 mg/dl
   b. 1-hr plasma glucose ≥180 mg/dl
   c. 2-hr plasma glucose ≥153 mg/dl
- After pregnancy, women with GDM have an increased risk of developing diabetes during their lifetime. Women with GDM should be screened at or after 6 weeks postpartum with a 75-g 2-hour GTT to diagnose type 2 diabetes using the same criteria as nonpregnant patients. Alternatively, an HgbA1c can be performed at or after 12 weeks postpartum.

IMAGING STUDIES

Ultrasound for fetal size is performed in women with GDM. It may be initiated at the time of diagnosis and repeated every 3 to 4 weeks if macrosomia is suspected. Clinicians should consider local standards of care.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Glucose monitoring:
  1. Four times daily: Fasting and 2-hr postprandial (defined as 2 hr after the start of each meal).
  2. Goals: Fasting <95 mg/dl; 2-hr postprandial <120 mg/dl.
  3. Can also use 1-hr postprandial goal of <140 mg/dl.
- Dietary modifications for glycemic control:
  1. Follow a low-carbohydrate diet; avoid sugar and concentrated sweets; and eat small, frequent meals (three meals with two snacks is often recommended).
  2. Complex carbohydrates should be consumed over simple carbohydrates to prevent glucose fluctuations.
  3. Diet should adequately meet the needs of pregnancy (below) while restricting carbohydrates to 33% to 40% of daily calories. Caloric needs in pregnancy:
     a. BMI <30: 30 kcal/kg/day.
     b. BMI >30: 25 kcal/kg/day.
     c. BMI >40: 12 to 14 kcal/kg/day.
  4. Regular moderate exercise, defined as 30 minutes five times per week.
  5. Ongoing nutrition counseling throughout pregnancy.

PHARMACOLOGIC Rx

Initiate if >20% of glucose values are elevated after trial of diet control:

- Insulin: Considered the gold standard in GDM management.
  1. There are no randomized controlled trials on insulin regimens, and therapy is largely guided by expert opinion.
  2. Insulin is the only FDA-approved medication for GDM (Pregnancy Class B) and does not cross placenta.
  3. Insulin may be started first line or added when oral medications have failed to achieve glycemic control. The authors consider factors such as the degree of hyperglycemia, obstacles to medication adherence, and gestational age at time of diagnosis (with early-onset diagnosis more likely to progress and require insulin) when initiating therapy. The ADA recommends insulin as first-line pharmacotherapy for GDM, and ACOG (2017) mirrors this recommendation (Level A).
  4. Regardless of insulin regimen initiated, blood glucose values should be reviewed frequently, and the regimen adjusted and customized to optimize each woman's blood glucose levels; using a single agent or combination of long, intermediate and/or short-acting insulins.
  5. One commonly used regimen:
     a. Insulin 0.7 to 1.0 U/kg/day SQ (based on current pregnant weight), with two thirds of the total daily dose given in the morning and one third of the total daily dose given in the evening.
     b. One third of each dose is given as short-acting insulin and the remaining two thirds as long-acting insulin.
- Oral hypoglycemics:
  1. Oral antidiabetic agents continue to be used in the management of GDM, despite a lack of FDA approval for this indication.
  2. Several recent studies have examined the potential benefits and harms of metformin and glyburide, comparing them with the gold-standard insulin and with each other. Metformin (compared with insulin) has been demonstrated to decrease maternal glucose levels, maternal weight gain, and the risk of gestational hypertension. Evidence grows that it may decrease the risk of preeclampsia as well. Although known to cross the placenta, concerns about the long-term risk in exposed offspring have been mitigated by at least one recent study showing no neurodevelopmental differences with intrauterine exposure to metformin versus insulin. Meanwhile, recent meta-analyses have demonstrated worse neonatal outcomes with the use of glyburide compared with insulin. With both metformin and glyburide, many women go on to require insulin therapy.
  3. As of 2017, ACOG recommends "in women who decline insulin therapy or for those women whom the obstetrician or obstetric care provider believes the patient will be unable to safely administer insulin, metformin is a reasonable second-line choice" (Level B); while suggesting that glyburide should not be recommended as a first-line agent due to a failure to achieve equivalent outcomes to insulin in most studies (also Level B).
  4. Metformin: Begin at 500 mg PO nightly or bid, and titrate up to a maximum of 2500 mg daily in divided doses.
  5. Glyburide: Begin at 2.5 mg qd, and titrate up to a maximum of 20 mg qd (10 mg bid). Increase dose as needed by 2.5 to 5 mg/wk.

ANTENATAL TESTING

Antepartum testing is recommended for women with pregestational diabetes and gestational diabetes. There is no consensus regarding initiation, frequency or modality of antepartum testing in gestational diabetes, and this should be guided by local standards.

ONE COMMONLY USED REGIMEN

- Weekly NST/AFI beginning at 32 weeks or when medications are initiated in women with GDMA2. Less frequent testing or delayed initiation of testing may be considered in women who maintain glycemic control with diet alone (GDMA1), as increased rates of stillbirth have not been observed in these women before 40 weeks' gestation.
- Preexisting or poorly controlled diabetes, vascular complications, or concomitant hypertension: Twice weekly NST/AFI beginning at 28 weeks. Consider hospital admission to obtain glycemic control.

TIMING AND ROUTE OF DELIVERY

- Women with preexisting diabetes should be induced at 39 weeks.
- Women with GDMA2 may also be induced at 39 weeks unless otherwise indicated, with decisions regarding induction guided by local standards of care.
- In women with GDMA1, ACOG supports expectant management of up to 40 and 6/7 weeks with appropriate antepartum testing.
- Counsel regarding elective cesarean section at or after 39 weeks if estimated fetal weight is over 4500 g.
- Consider delivery earlier than 39 weeks if poor glycemic control or other medical indications such as growth restriction or preeclampsia.

INTRAPARTUM MANAGEMENT

- Goal is normoglycemia (80 to 120 mg/dl) using insulin and D5 lactated Ringer IV fluid if needed.
- Monitor glucose every 1 to 2 hours in active labor.
- Preparation for shoulder dystocia.
- If on glyburide, discontinue in labor or 12 hr before a scheduled induction.
- If on insulin consider decreased long-acting insulin by one third to one half before scheduled induction. Most experts recommend holding insulin entirely the morning of a scheduled cesarean delivery.

POSTPARTUM MANAGEMENT

- Class A2: Check fasting blood glucose level before discharge; if abnormal, continue checking at home and schedule early follow-up with primary care physician to confirm diagnosis of DM.
- 6-wk postpartum visit: Screen for impaired glucose tolerance and diabetes with a 75 g, 2-hr glucose tolerance test. Alternatively, an HgbA1c may be performed at or after 12 weeks postpartum.

- If no evidence of DM, screen annually for DM and counsel on risk factor modification.

REFERRAL

- Nutritionist
- Maternal-fetal medicine
- Diabetes educator
- Nurse care manager, when available

COMPLICATIONS

- Maternal: Preeclampsia, future type 2 DM or GDM, operative delivery
- Fetal: Polyhydramnios, macrosomia, congenital malformations, shoulder dystocia, birth trauma, IUFD
- Neonatal: Hypoglycemia, hypocalcemia, hyperbilirubinemia, polycythemia, perinatal death, respiratory distress, future obesity, and DM

PEARLS & CONSIDERATIONS

- Trials have shown that although treatment of mild gestational DM did not significantly reduce the frequency of a composite outcome that included stillbirth or perinatal death and several neonatal complications, it did reduce the risks of fetal overgrowth, shoulder dystocia, cesarean delivery, and hypertensive disorders.
- Lactation improves maternal glucose metabolism and may prevent or delay the development of type 2 DM following GDM. Higher lactation intensity and longer duration are independently associated with lower 2-yr incidences of DM after a GDM-affected pregnancy.

PREVENTION

Regular exercise, maintenance of ideal body weight, and high-fiber low-glycemic diet

Giant Cell Arteritis ALG PTG

BASIC INFORMATION

DEFINITION

Giant cell arteritis (GCA) is a segmental systemic granulomatous arteritis affecting medium and large arteries in individuals >50 yr. Inflammation primarily targets branches of the extracranial head and neck blood vessels (external carotids, temporal arteries, ciliary and ophthalmic arteries). The aorta and subclavian and brachial arteries can also be affected. Intracranial arteritis is rare.

SYNONYMS

Temporal arteritis
Cranial arteritis
GCA
Horton disease

ICD-10CM CODES

M31.5 Giant cell arteritis with polymyalgia rheumatica
M31.6 Other giant cell arteritis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Approximately 20 new cases per 100,000 persons >50 yr; peak incidence is in patients ages 60 to 80 yr.
PREVALENCE: 200 cases per 100,000 persons; it is the most common primary vasculitis; female/male predominance of twofold to fourfold; more common in Caucasians.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

GCA can present with the following clinical manifestations:

TABLE 1 Atypical Manifestations of Giant Cell Arteritis

Fever of unknown origin
Respiratory symptoms (especially cough)
Otolaryngeal manifestations
Glossitis
Lingual infarction
Throat pain
Hearing loss
Large-artery disease
Aortic aneurysm
Aortic dissection
Limb claudication
Raynaud phenomenon
Neurologic manifestations
Peripheral neuropathy
Transient ischemic attack (TIA) or stroke
Dementia
Delirium
Myocardial infarction
Tumorlike lesions
Breast mass
Ovarian and uterine mass
Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
Microangiopathic hemolytic anemia

From Harris ED et al: *Kelly's textbook of rheumatology,* ed 7, Philadelphia, 2005, Saunders.

- Headache, often associated with marked scalp tenderness—noticed while brushing hair (hair comb allodynia)
- Constitutional symptoms (fever, weight loss, anorexia, fatigue)
- Polymyalgia rheumatica (aching and stiffness of the trunk and proximal muscle groups)
- Visual disturbances (transient or permanent monocular or binocular visual loss)
- Intermittent claudication of jaw and tongue on mastication that is especially prominent when solid food such as steak is chewed
- Table 1 describes atypical manifestations of GCA

Important physical findings in GCA:

- Vascular examination: The temporal artery demonstrates tenderness, decreased pulsation, and nodularity (ropy) (Fig. E1); diminished or absent pulses in upper extremities may be seen.

ETIOLOGY

Vasculitis of unknown etiology. An association with HLA-DRB*04 has been identified. Recent demonstration of varicella zoster virus virion, antigen, and DNA within the vessel walls of the temporal arteries on histopathologic specimens of giant cell arteritis suggest an association.

DIAGNOSIS

Clinical history and vascular examination remain cornerstones of diagnosis. An algorithm for diagnosing GCA is described in Fig. 2. The American College of Rheumatology has proposed classification criteria to aid in the diagnosis of GCA. Presence of three or more of these criteria in a patient with suspected vasculitis is considered to be suggestive of GCA:

- Age of onset of symptoms >50 yr
- New-onset of or new type of localized headache
- Temporal artery abnormalities including tenderness or decreased pulsation
- Westergren erythrocyte sedimentation rate (ESR) elevated (typically >50 mm/hr)
- Temporal artery biopsy with vasculitis and mononuclear cell infiltrate or granulomatous changes

DIFFERENTIAL DIAGNOSIS

- Other vasculitic syndromes
- Nonarteritic anterior ischemic optic neuropathy (NAION)
- Pituitary apoplexy
- Primary amyloidosis
- Transient ischemic attack, stroke
- Infections
- Occult neoplasm, multiple myeloma

LABORATORY TESTS

- ESR elevated although up to 22% of patients with GCA have normal ESR before treatment.
- C-reactive protein (CRP) is typically included in laboratory investigation; it may have greater sensitivity than ESR. CRP typically rises before the ESR.
- Mild to moderate normochromic normocytic anemia, elevated platelet count.

IMAGING STUDIES

Imaging studies do not play a major role in diagnosing GCA and are rarely indicated:

- Color duplex ultrasonography (CDUS) of temporal artery produces three characteristic features—periluminal "halo" over the temporal artery involved, segmental arterial stenosis, and arterial luminal occlusion in severe cases. CDUS of the temporal artery has 40% to 75% sensitivity and 79% to 83% specificity for diagnosis of GCA. Clinical utility is not superior to clinical examination with biopsy.

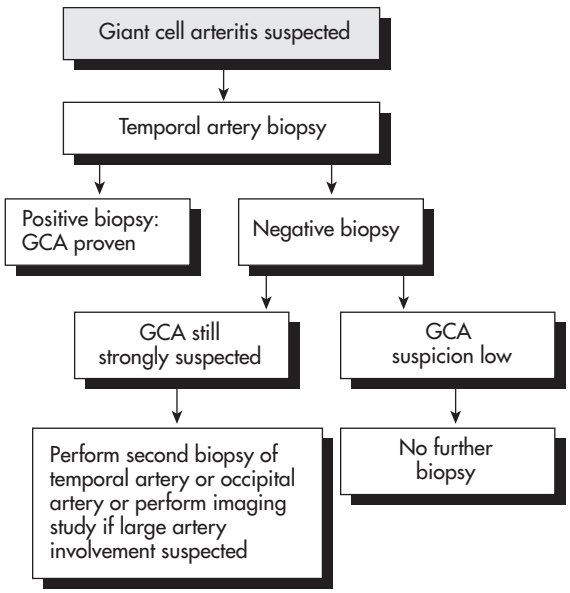

FIG. 2 Algorithm for diagnosing giant cell arteritis *(GCA).* (From Firestein GS et al: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.)

- Contrasted MRI of temporal artery may be performed in patients with contraindications to surgical biopsy of the superficial temporal artery if treatment with steroids has not been initiated. MRI has a 78.4% sensitivity and 90.4% specificity in detecting temporal artery involvement in patients with a clinical diagnosis of GCA.
- Angiography of the arms is indicated in patients with peripheral vascular insufficiency.
- Fluorine-18-fluorodeoxyglucose (18F-FDG) positron emission tomography/computed tomography (18F-FDG PEA/CT) imaging may be used to detect large-vessel inflammation in GCA. Sensitivity is 64% in the maxillary or temporal arteries and increases to 82% if vertebral arteries and increases specificity is 100%.

Rx TREATMENT

ACUTE GENERAL Rx

- If there is clinical suspicion of GCA, treatment should be initiated without waiting for results of laboratory or imaging studies.
- IV methylprednisolone (250 to 1000 mg for 1 to 3 days) is considered standard of care in patients with severe clinical manifestations such as visual loss from ischemic optic neuropathy.
- Oral prednisone (1 mg/kg/day): High-dose oral regimen should be continued at least until symptoms resolve and ESR returns to normal; usually 3 to 4 wk after treatment initiation. Steroid taper is very slow (10% to 20% per mo) with monitoring of clinical features as well as ESR and CRP. When dose <10 mg/day, taper by 1 mg/mo. Treatment may last up to 2 yr or more.
- Although corticosteroids have traditionally been the treatment of choice, tocilizumab, an IL-6 receptor blocker, was recently approved by the FDA for the treatment of GCA. Patients treated with tocilizumab and prednisone achieved remission faster, had a greater reduction in steroid dosage, and had prolonged maintenance of remission when compared with those treated with prednisone alone.
- There is no evidence for the role of other steroid-sparing agents.

DISPOSITION

- With steroid therapy there is a dramatic improvement of systemic symptoms, but not vision in patients with ischemic optic neuropathy. In one study only 4% of eyes improved in both visual acuity and central visual field.
- Management of flares: Repeat prednisone induction if patient experiences severe flare. If mild flare, increase prednisone by 10% to 20% and slow down prednisone taper.

REFERRAL

- Surgical or ophthalmologic referral for biopsy of temporal artery
- Rheumatology referral for long-term immunosuppressive treatment management

PEARLS & CONSIDERATIONS

- Treatment of GCA should be started if there is clinical suspicion of the disease. This usually includes patients above the age of 50 presenting with a severe headache and systemic features that suggest GCA as well. Physicians should not wait for laboratory or pathologic confirmation before starting treatment as the risk of visual loss increases. Blindness from untreated GCA is permanent.
- Temporal artery biopsy should be performed as soon as possible, but within 2 wk of initiating treatment with steroids. The biopsy may remain positive for 2 to 6 wk after initiation of corticosteroids.
- Treatment should not be withheld pending temporal artery biopsy.

COMMENTS

- The relation between polymyalgia rheumatica and GCA is unclear, but the two frequently coexist. They are considered to be different points along the gradient or spectrum of the same disease.
- Clinical picture rather than ESR should be the prime yardstick for continuing prednisone therapy. A rising ESR in a clinically asymptomatic patient with normal hematocrit should raise suspicion for alternate explanations (e.g., infections, neoplasms).
- GCA is associated with a markedly increased risk for the development of aortic aneurysm, which is often a late complication and may cause death. Annual chest radiograph in chronic CGA patients has been suggested, as well as emergent chest CT or MRI for clinical suspicion.
- GCA is also associated with increased risk of myocardial infarction, stroke, and peripheral vascular disease.
- Coadministration of low dose aspirin (81 mg/day) has been reported by some as effective for further reduction of risk of blindness. Additional trials may be needed before it can be recommended as standard therapy.

Giant Cell Myocarditis

BASIC INFORMATION

DEFINITION

Giant cell myocarditis (GCM) is a rare but frequently fatal inflammatory disorder that affects the myocardium characterized by widespread infiltration in the myocardial tissue of multinucleated giant cells and myocardiocyte necrosis that is not secondary to ischemic events or cardiac rejection in the setting of transplantation. Giant cells are abnormal masses produced by the fusion of inflammatory cells called macrophages. Patients may develop acute or fulminant deterioration in left ventricular systolic function despite standard heart failure treatment, ventricular arrhythmias, and heart block.

SYNONYMS

GCM
Idiopathic myocarditis
Isolated myocarditis

ICD-10CM CODE
I40.1 Giant Cell Myocarditis (acute or subacute); Isolated Myocarditis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Overall, the incidence of GCM is low. Autopsy series report an incidence of GCM ranging from 0.007% to 0.051%.
PREDOMINANT SEX AND AGE: In a large multicenter registry of GCM cases ($n = 63$) patients ranged in age from 16 to 69 yr at the time of symptom onset, with an average patient age of 42.6 yr. GCM affects males and females in equal numbers.
GENETICS: Gene expression analysis of GCM shows that altered expression of T-cell activation genes (immune response genes), such as chemokine receptor 4; chemokine ligans 5, 9, 13, and 19; interleukin-1 receptor alpha to interleukin-10 receptor alpha; and beta-2 integrin, may play a role in its pathogenesis. Additional studies are required in order to further elucidate potential therapeutic targets for GCM.
RISK FACTORS: Approximately 20% of patients who develop GCM have a history of an autoimmune disorder, including ulcerative colitis or Crohn disease and hyperthyroidism.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Approximately 75% of patients present with congestive heart failure (CHF). Shortness of breath/dyspnea on exertion accompanied by fatigue and decreased exercise capacity can be the initial manifestations of CHF
- Increased jugular venous pressure, an S3 murmur, hepatomegaly, and peripheral edema may present in worsening heart failure, specifically right ventricular failure
- Signs of inadequate perfusion with acute progression of heart failure leading to cardiogenic shock, including hypotension, low pulse pressure, cool extremities, persistent tachycardia, and mental status changes
- Ventricular arrhythmia (14%): Ventricular tachycardia with possible deterioration to ventricular fibrillation or sudden cardiac death (SCD)
- Heart block (5%): Ranging from first-degree to complete atrioventricular block
- Initial symptoms resembling an acute myocardial infarction, such as chest pain, present in up to 6% of patients with GCM
- Syncope/presyncope, dizziness, palpitations, or lightheadedness secondary to heart block or ventricular arrhythmia

ETIOLOGY

- The etiology of giant cell myocarditis is insufficiently known but commonly attributed to immune dysregulation mediated by T lymphocytes.
- The strong association of GCM with autoimmune disorders, as well as tumors of immune cells such as thymoma and lymphoma, would also suggest a process of dysregulated immunity.
- Recent gene expression profiling of patients with GCM has revealed upregulation of genes involved in the T-cell immune response.
- Other rarely reported conditions in association with the development of GCM include drug hypersensitivity reaction and infection such as parvovirus B19 (diagnosed via DNA polymerase chain reaction [PCR]) or coxsackie B2 virus (diagnosed via serology and cardiac immunoblotting). However, no microbiologic agent has been directly identified in cardiac tissue by microscopy, tissue culture, or inoculation in experimental animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ischemic or nonischemic cardiomyopathy
- Acute coronary syndrome
- Other infiltrative diseases of the myocardium, such as sarcoidosis, lymphocytic, and hypersensitivity myocarditis (Table 1)

WORKUP

- Medical history to determine various etiologies of myocarditis, specifically history of autoimmune disorders.
- Diagnostic workup includes chest x-ray, ECG, laboratory evaluation, echocardiogram, cardiac catheterization, cardiac MRI with late gadolinium enhancement, and endomyocardial biopsy.

LABORATORY TESTS

- N-terminal brain natriuretic propeptide (NT-pro BNP) is recommended if heart failure symptoms are present.
- Increased levels of CKMB, troponin I or T, lactate dehydrogenase, and aspartate aminotransferase are present in the setting of myocardial necrosis.

IMAGING STUDIES

- Chest x-ray: Enlargement of the cardiac silhouette with or without pulmonary congestion.
- ECG: Sinus tachycardia with nonspecific ST-T wave changes, intraventricular conduction defects, and bundle branch blocks are common manifestations in idiopathic giant cell myocarditis. Ventricular arrhythmias or heart blocks may also be present.
- Echocardiogram: Acute severe myocarditis is associated with global systolic dysfunction and decreased ejection fraction. The left ventricle may be dilated or hypokinetic. Abnormal tissue Doppler signal can provide additional evidence for the presence of myocarditis.
- Cardiac catheterization and angiography: Used to rule out coronary artery disease and valvular disease. Patients with GCM will most commonly have a normal coronary arteries.
- Cardiac MRI can be used to detect myocardial edema and myocyte injury in myocarditis. It has the sensitivity and specificity of approximately 80% for diagnosing acute myocarditis. Late gadolinium enhancement (LGE) demonstrates myocardial damage from inflammation or fibrosis. Combining T2 imaging with LGE can help distinguish acute inflammation from chronic injury.
- F-18 fluorodeoxyglucose combined with positron emission tomography (FDG-PET) can assess the severity of myocardial inflammation, as well as likelihood of disease progression to fibrosis, dilated cardiomyopathy, and heart failure.
- Endomyocardial biopsy (EMB) is considered the gold standard for diagnosis. The sensitivity of right ventricular EMB for GCM is 80% to 85%; it is 93% with repeated biopsy, or with combined right and left ventricular biopsies. Histopathology reveals the presence of giant cells, granulomas (less frequently), the character of inflammation (lymphocytes, eosinophils, macrophages), and the presence of myocyte hypertrophy and interstitial fibrosis (Fig. E1).
- It is important to distinguish between various types of inflammatory myocarditis because survival among patients in whom GCM is diagnosed on the basis of endomyocardial biopsy or apical wedge sampling is worse than patients with either cardiac sarcoid or lymphocytic myocarditis.
- GCM usually has diffuse or multifocal involvement of the endocardium; therefore EMB tends to have a higher diagnostic sensitivity in GCM than in cardiac sarcoidosis (35%) or lymphocytic myocarditis (25%).

TREATMENT

Cyclosporine-based combined immunosuppression may be able to reduce myocardial inflammation and improve clinical outcome. The goal of immunosuppression therapy is to delay heart transplantation and delay transplant. Cessation or sometimes reduction of immunosuppression is associated with GCM recurrence as far as 8 yr after diagnosis. Heart transplantation is frequently inevitable. The rate of death or cardiac transplantation was 89% with a median survival

TABLE 1 Features of Select Causes of Inflammatory Myocarditis

Inflammatory Disorder	Histologic Features	Common Presentations	Diagnosis	Treatment Monitoring
CS	Granulomas, in the absence of infection. Eosinophils and necrosis rare or absent.	Heart block, ventricular arrhythmias, more indolent cardiomyopathy	Clinical, electrocardiographic, and advanced imaging with ^{18}F-FDG PET or CMR. EMB sensitivity increased by ventricular voltage mapping. Basal septal aneurysm is rare but specific.	Clinical status, arrhythmia monitoring, natriuretic peptides, LV function, and possibly serial PET imaging.
Idiopathic GCM	Necrotizing inflammation with lymphocytes, eosinophils, histiocytes, and multinucleated giant cells often near the region of myocyte damage. No well-formed granulomas.	Ventricular tachycardia in the setting of acute or fulminant systolic heart failure with/without heart block. Progressive course over wks to mos, requiring inotropic and/or mechanical circulatory support.	EMB	Clinical status, assessment of ventricular function, repeat EMB indicated for suspected recurrent disease.
Eosinophilic myocarditis	Endocardial or perivascular forms. Extensive myocyte damage suggests necrotizing eosinophilic myocarditis or very early GCM.	Heart failure related to valvular involvement. Thrombi with peripheral emboli are common.	CMR. Disease may be isolated to the LV, decreasing the diagnostic use of right ventricular EMB.	Clinical status, assessment of ventricular function, CMR for tissue characterization, peripheral eosinophil count if initially elevated.
Lymphocytic myocarditis	Lymphocyte predominant, nonischemic infiltrate with or without myocyte necrosis (borderline if no myocyte damage).	Heart failure with a dilated LV. Fulminant disease associated with a smaller ventricular size and thicker walls.	CMR	Clinical status, natriuretic peptides, assessment of ventricular function.

CMR, Cardiac magnetic resonance; *CS,* cardiac sarcoidosis; *EMB,* endomyocardial biopsy; *GCM,* giant cell myocarditis; *LV,* left ventricle; *PET,* positron emission tomography; *^{18}F-FDG,* ^{18}F-fluorodeoxyglucose.

From Kadkhodayan A et al: Imaging of inflammation in unexplained cardiomyopathy, *JACC Cardiovasc Imaging* 9(5):603-617, 2016.

of 5.5 mo from the onset of symptoms to the time of death or transplantation.

The prognosis of GCM with no or limited immunosuppressive therapy is poor. Without appropriate immunosuppressive therapy, the median survival from GCM symptom onset to death or transplant is only 3 mo. With appropriate immunosuppressive therapy, the 5-yr survival rate free of transplant ranges from 52% to 72%.

NONPHARMACOLOGIC THERAPY

Mechanical circulatory support may be required for acute decompensated heart failure. Cardiac transplantation is often required.

ACUTE GENERAL Rx

- Immunosuppressive therapy: Usually involves a combination of muromonab-CD3, cyclosporine, azathioprine, and corticosteroids with mycophenolate mofetil a potential substitute for azathioprine.
- Antiarrhythmic drugs (AADs) for ventricular arrhythmias including amiodarone, sotalol, and mexiletine. Sustained arrhythmias should be treated with urgent cardioversion.
- Treatment for heart failure with reduced ejection fraction includes angiotensin-converting enzyme inhibitor (or angiotensin receptor blocker) and evidence-based beta blocker.
- Catheter or surgical ablation for VT.
- Mechanical circulatory support and cardiac transplant: Potential options for patients with refractory heart failure or cardiogenic shock include ventricular assist device (VAD) or extracorporeal membrane oxygenation (ECMO). Cardiac transplant needs to be considered soon after diagnosis. GCM can recur in ~25% of transplanted hearts.

DISPOSITION

- GCM has a significantly worse prognosis compared with lymphocytic or presumed viral myocarditis.
- Immunosuppression must be continued long term as GCM can recur up to 8 yr after diagnosis if immunosuppressive therapy is tapered or terminated.
- Even with long-term immunosuppression, patients remain at risk of developing ventricular arrhythmias and may require ICD.
- Rate of death or cardiac transplant was 89% and the median survival from onset of symptoms was 5.5 mo.

REFERRAL

- Implantation of a cardiac defibrillator should be considered (class IIa indication) in GCM, with this diagnosis as the sole criterion in patients who have reasonable expectation of survival with a good functional status for more than 1 yr. Permanent ICD is not recommended until the resolution of the acute phase and a wearable external defibrillator may be considered during recovery.
- Endomyocardial biopsy is the gold standard and should be performed when there is clinical suspicion present.
- Most patients will require heart transplant despite aggressive treatment with immunosuppressive therapy.
- Catheter or surgical VT ablation may be considered in patients with recurrent ventricular arrhythmias; however, success rate in this population is unknown.
- Complete heart block and symptomatic bradycardia are indications for pacing during acute phase of GCM.

PEARLS & CONSIDERATIONS

- Rapid diagnosis is critical, as the management differs from that of other myocardial processes containing giant cells, and early institution of combined cyclosporine-based immunosuppression can dramatically affect the disease course by reducing inflammation and improving transplant-free survival.
- Owing to advancements in diagnostic and therapeutic options, it is now increasingly diagnosed on the basis of endomyocardial biopsies, explanted hearts, or apical wedge sections removed at the time of ventricular assist device placement.

A, Active GCM characterized by an intense lymphoplasmacytic and eosinophilic infiltrate with scattered multinucleated giant cells *(arrowheads),* associated with myocyte injury and necrosis (hematoxylin and eosin staining, 100× original magnification). **B,** Recurrent GCM, characterized by a lymphoplasmacytic infiltrate with rare multinucleated giant cell *(arrowhead)* (hematoxylin and eosin staining, 100× original magnification). **C,** Moderate myocyte hypertrophy with moderate interstitial (replacement-type) fibrosis, likely representing myocarditis-associated injury (hematoxylin and eosin staining, 100× original magnification). (From Maleszewski J et al: Long-term risk of recurrence, morbidity and mortality in giant cell myocarditis, *Am J Cardiol* 115(12):1733-1738, 2015.)

BASIC INFORMATION

DEFINITION

Giardiasis is an intestinal and/or biliary tract infection caused by the noninvasive protozoal parasite *Giardia intestinalis* (also known as *G. lamblia* or *G. duodenalis*). The organism is a widespread zoonotic parasite and frequently contaminates fresh water sources worldwide.

SYNONYMS

Giardiasis
Giardia duodenalis (accepted species name by the CDC)
Giardia intestinalis

ICD-10CM CODE
A07.1 Giardiasis [lambliasis]

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):
- Exact incidence unknown. CDC estimates 20,000 cases a yr in the U.S.
- Frequently occurs as waterborne outbreaks in international adoptees, travelers, immunocompromised patients, and those with cystic fibrosis.
- *G. lamblia* has been demonstrated in 4% to 7% of submitted stool specimens, making it the most commonly identified intestinal parasite.

PREVALENCE (IN U.S.): 4%
PREDOMINANT SEX: Male = female
PREDOMINANT AGE:
- Preschool children, especially if in day care
- 20 to 40 yr of age, especially among sexually active homosexual men (oral-anal contact)

PEAK INCIDENCE:
- Varies with risk factors, outbreaks, but peak onset from early summer through early fall
- All age groups affected

GENETICS: Familial disposition: Patients with common variable immunodeficiency or X-linked agammaglobulinemia are at increased risk of infection.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- More than 70% with one or more intestinal symptoms (diarrhea, flatulence, cramps, bloating, nausea). Table 1 summarizes clinical signs and symptoms of giardiasis
- Incubation period averages 7 to 21 days
- Fever in <30%
- Chronic diarrhea, malabsorption, and weight loss, which can be up to 10% of body weight, are common
- GI bleeding is unusual
- Continuous or intermittent symptoms, lasting for 2 to 4 wk
- Of infected patients, 20% to 25% are asymptomatic and can shed cysts for months

TABLE 1 Symptoms of Giardiasis

Symptom	Frequency (%)
Flatulence	56-74
Anorexia	40-64
Abdominal cramps	55-80
Foul-smelling stool	57-72
Abdominal distention	31
Bloating	55-69
Nausea	58-68
Malaise	84
Diarrhea	89
Belching	30
Weight loss	48-64
Fever	17-28

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

ETIOLOGY

Infection is acquired by ingestion of viable cysts of the organism (Fig. 1), typically in contaminated water or food or by fecal-oral contact. *Giardia* cysts are resistant to chlorination and survive well in cold mountain streams.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other agents of infective diarrhea (amebae, *Salmonella* sp., *Shigella* sp., *Staphylococcus aureus, Cryptosporidium*, etc.)
- Noninfectious causes of malabsorption

WORKUP

- Stool specimen (three specimens yield 90% sensitivity) as a saline suspension or duodenal aspirate for microscopic examination to establish diagnosis and exclude other pathogens
- Immunoassays for *Giardia* sp. Antigens in stool samples such as the DFA or ELISA are now routinely used in most clinical laboratories. These assays are 85% to 98% sensitive and 90% to 100% specific. They are more sensitive than stool microscopy for confirming the diagnosis. They also have a faster turnaround time.

LABORATORY TESTS

Serum albumin, vitamin B_{12} levels, and stool fat test to exclude malabsorption

IMAGING STUDIES

- Not necessary unless biliary obstruction is suspected
- In detection of organism, possible interference by barium in stool from radiographic studies

TREATMENT

NONPHARMACOLOGIC THERAPY

Avoidance of milk products to reduce symptoms of transient lactase deficiency that occur in many patients and can last for wk to mo

GENERAL Rx

Adult and pediatric (Table E2):
- Metronidazole 250 mg PO three times daily for 5 to 10 days. Pediatric dose: 5 mg/kg tid × 7 days (metronidazole should be avoided in pregnancy)
- Alternative regimen: Tinidazole: 2 g single dose (50 mg/kg in children over 3 yr of age)
- Nitazoxanide: aged 12 to 47 mo: 100 mg bid × 3 days. Aged 4 to 11 yr: 200 mg bid × 3 days
- Quinacrine: 100 mg po tid × 5 to 7 days
- Albendazole 400 mg PO qd × 5 days
- Paromomycin 25 to 35 mg/kg/day in three doses for 5 to 10 days. Safe for pregnancy

DISPOSITION

Reinfection is possible. Postinfection lactose intolerance is common and is frequently mistaken for recurrent infection.

PEARLS & CONSIDERATIONS

COMMENTS

Travelers to endemic areas (developing world, wilderness areas) should be cautioned to boil drinking water or use water purification tablets (for iodine-containing products, chlorination is not effective). Chronic giardiasis as seen in developing nations can cause delays in growth and development in children due to malabsorption and diarrhea.

TABLE E2 Drugs for the Treatment of Giardiasis

Drug	Dose	Efficacy (%)	Side Effects
Metronidazole	15 mg/kg/day orally divided 3 times a day for 5-10 days (maximum, 750 mg/day)	80-100	Metallic taste, headache, nausea, vomiting, rash, peripheral neuropathy, neutropenia, disulfiram-like effects
Tinidazole	50 mg/kg, single dose (maximum, 2 g)	80-96	Metallic taste, nausea, vomiting, headache, rash, peripheral neuropathy, neutropenia, disulfiram-like effects
Ornidazole[a]	40-50 mg/kg, single dose (maximum, 2 g)	96-100	Metallic taste, nausea, vomiting, headache, rash, peripheral neuropathy, neutropenia, disulfiram-like effects
Secnidazole	2 g, single dose	90	Nausea, anorexia, abdominal pain
Albendazole[b]	15 mg/kg per day for 5-7 days (maximum, 400 mg/day)	94-100	Anorexia, constipation, neutropenia, elevated liver function test results
Furazolidone	6 mg/kg per day orally divided 4 times a day for 10 days	81-96	Allergic reactions, headache, nausea, vomiting, diarrhea, brown discoloration of urine, hemolysis, disulfiram-like effects
Paromomycin	30 mg/kg per day divided 3 times a day for 5-10 days (maximum, 1.5 g/day)	55-88	Nausea, vomiting, ototoxicity, nephrotoxicity
Quinacrine[a]	6 mg/kg per day divided 3 times a day for 7 days	92-95	Nausea, vomiting, dizziness, headache, yellow or orange skin and mucous membrane discoloration, hemolysis, toxic psychosis
Nitazoxanide	1-3 yr: 200 mg/day divided 2 times a day for 3 days 4-11 yr: 400 mg/day divided 2 times a day for 3 days ≥12 yr: 1000 mg/day divided 2 times a day for 3 days	85-90	Nausea, abdominal pain, diarrhea, anorexia, flatulence, headache, yellow eyes, discolored urine, increased creatinine and serum glutamic-pyruvic transaminase levels

[a]No longer produced in the U.S. Can be obtained from Panorama Pharmacy, Panorama City, CA.
[b]Not approved by the U.S. Food and Drug Administration for this indication in the U.S.
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

BASIC INFORMATION

DEFINITION

Gilbert syndrome is an autosomal-dominant disorder characterized by indirect hyperbilirubinemia caused by impaired glucuronyl transferase activity.

SYNONYM

Gilbert disease

ICD-10CM CODE
E80.4 Gilbert syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Probable autosomal-dominant disease affecting >5% of the U.S. population
PREDOMINANT SEX: Male:female ratio of 3:1
GENETICS: Most common hereditary hyperbilirubinemia (genotypic prevalence 12%)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- No abnormalities on physical examination other than mild jaundice when bilirubin exceeds 3 mg/dl.
- A family history of unconjugated hyperbilirubinemia may be present.

ETIOLOGY

- Decreased elimination of bilirubin in bile is caused by inadequate conjugation of bilirubin.
- Alcohol consumption and starvation diet can increase bilirubin level.
- The pathogenesis of Gilbert syndrome has been linked to a reduction in the bilirubin UGT-1 gene *(HUG-Brl)* transcription, resulting from a mutation in the promoter region.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hemolytic anemia
- Liver disease (chronic hepatitis, cirrhosis)
- Crigler-Najjar syndrome

WORKUP

- Most patients are diagnosed during or after adolescence, when isolated hyperbilirubinemia is detected as an incidental finding on routine biochemical testing.
- Laboratory evaluation to exclude hemolysis and liver diseases as a cause of the elevated bilirubin level (Table 1 and Fig. 1).

LABORATORY TESTS

Elevated indirect (unconjugated) bilirubin (rarely exceeds 5 mg/dl)

TABLE 1 Characteristic Patterns of Liver Function Tests

Disorder	Bilirubin	Alkaline Phosphatase	AST	ALT	Prothrombin Time	Albumin
Gilbert syndrome (abnormal bilirubin metabolism)	↑	NL	NL	NL	NL	NL
Bile duct obstruction (pancreatic cancer)	↑↑↑	↑↑↑	↑	↑	↑-↑↑	NL
Acute hepatocellular damage (toxic, viral hepatitis)	↑-↑↑↑	↑-↑↑	↑↑↑	↑↑↑	NL-↑↑↑	NL-↓↓
Cirrhosis	NL-↑	NL-↑	NL-↑	NL-↑	NL-↑↑	NL-↓↓

ALT, Alanine aminotransferase; *AST,* aspartate aminotransferase; *NL,* normal; ↑, increase; ↓, decrease (arrows indicate extent of change: ↑-↑↑↑, slight to large).
From Andreoli TE (ed): *Cecil essentials of medicine,* ed 6, Philadelphia, 2005, WB Saunders.

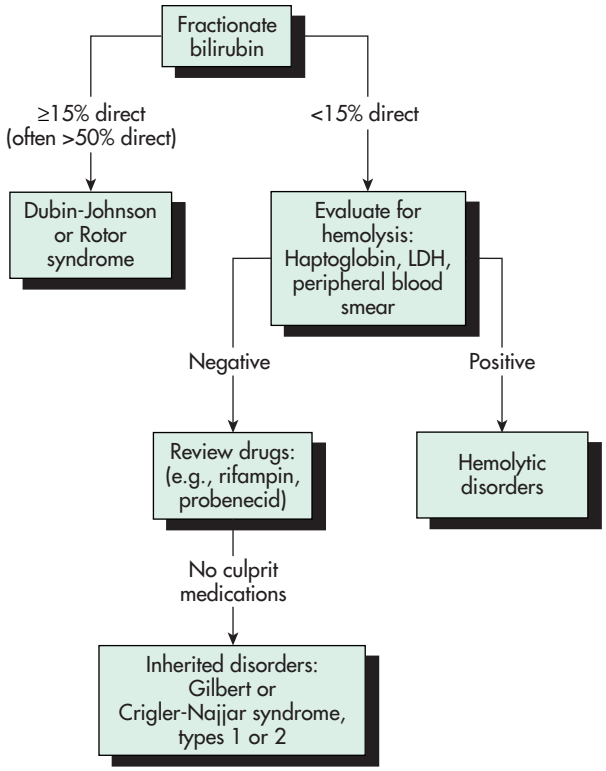

FIG. 1 Evaluation of an isolated elevation of the serum bilirubin level. *LDH,* Lactic dehydrogenase. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.)

TREATMENT

ACUTE GENERAL Rx

Treatment is generally unnecessary. Phenobarbital (if clinical jaundice is present) can rapidly decrease serum indirect bilirubin level.

DISPOSITION

Prognosis is excellent. Treatment is generally unnecessary.

REFERRAL

Referral is generally not necessary.

PEARLS & CONSIDERATIONS

COMMENTS

- Patients should be reassured about the benign nature of the condition.
- Fasting for 2 days or significant dehydration may raise the bilirubin level and result in the clinical recognition of jaundice.

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Inflammation of the gums covering the maxilla and mandible

ICD-10CM CODES

K05.0	Acute gingivitis
K05.1	Chronic gingivitis
K05.6	Other disorders of gingiva and edentulous alveolar ridge

EPIDEMIOLOGY & DEMOGRAPHICS

Gingivitis generally occurs in adults.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Inflammation is usually painless. Red velvety gingiva may be present (Fig. E1).
- Bleeding may occur with minor trauma such as brushing teeth.
- A bluish discoloration of the gums and halitosis are sometimes present.
- Subgingival plaque may be seen on close examination, and in time, there is detachment of soft tissue from the tooth surface.
- Long-standing infection may lead to destructive periodontal disease, which may involve teeth and bones.
- A dramatic form of gingivitis called acute ulcerative necrotizing gingivitis (ANUG or "trench mouth") can occur. This is manifested by acute, painful inflammation of the gingivae, with bleeding, ulceration, and halitosis. At times this is accompanied by fever and lymphadenopathy.
- Linear gingival erythema ("HIV gingivitis") presents as a brightly inflamed band of marginal gingiva. It may be painful, with easy bleeding and rapid destruction.
- Severe periodontitis can occur in patients with diabetes mellitus or HIV infection and in primary HIV infection (acute retroviral syndrome).
- Pregnancy may be associated with an acute form of gingivitis. Gingivae become inflamed and hypertrophic; this is likely the result of hormonal shifts.

ETIOLOGY

- A variety of organisms may be found in the environment of plaque. Anaerobes play a predominant role in periodontal disease.
  1. Bacteria playing a role in chronic disease include *Tannerella forsythia, Porphyromonas gingivalis,* and *Treponema denticola.*
  2. Porphyromonas gingivalis is considered the keystone pathogen as it secretes enzymes known as gingipains that cause tissue damage and immune disruption and changes to the normal oral commensal microbiota.
- Improper hygiene and poorly fitting dentures may contribute to the development of gingivitis.
- Excessive use of tobacco and alcohol may predispose individuals to gingival disease.
- In patients with HIV infection, gram-negative anaerobes, enteric organisms, and yeast predominate.
- Appropriate oral hygiene, such as flossing and tooth brushing, can prevent the accumulation of bacterial plaque; once dense plaque is present, adequate hygiene becomes more difficult.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Gingival hyperplasia, which may be caused by long-term use of phenytoin or nifedipine

WORKUP

Oral examination

LABORATORY TESTS

Elevated serum glucose in diabetics

IMAGING STUDIES

Radiographs of the teeth and facial bones may reveal extension of infection to these structures.

TREATMENT

NONPHARMACOLOGIC THERAPY

Removal of plaque, and at times, debridement of soft tissue

ACUTE GENERAL Rx

- Penicillin VK, 500 mg PO qid for 1 to 2 wk
- Clindamycin, 300 mg PO qid for 1 to 2 wk
- For linear gingival erythema, chlorhexidine gluconate rinses at a concentration of 0.2% and nystatin rinses or troches may be used

CHRONIC Rx

Extensive or recurrent infection may require periodic evaluation and debridement.

DISPOSITION

Continued inflammation can eventually lead to destruction of teeth and bone.

REFERRAL

Patients should be referred to a dentist or periodontist.

PEARLS & CONSIDERATIONS

COMMENTS

- Presence of periodontal disease is associated with an increased incidence of anaerobic pleuropulmonary infections.
- Existing data support the recommendation to change a toothbrush every 3 mo. Worn brushes seem to be less effective in plaque reduction.

Gingivitis, Necrotizing Ulcerative (NUG)

BASIC INFORMATION

DESCRIPTION

Necrotizing ulcerative gingivitis (NUG) is a distinct painful infectious disease primarily of the interdental and marginal gingiva. It is characterized by a symptom triad that includes gingival pain, ulcer, and bleeding.

SYNONYMS

NUG
Trench mouth
Acute necrotizing ulcerative gingivitis (ANUG)
Vincent stomatitis
Fusospirochetal gingivitis
Acute ulcerative gingivitis

ICD-10CM CODE
A69.0 Necrotizing ulcerative stomatitis

EPIDEMIOLOGY

INCIDENCE: Unlike in the developing world, NUG is seen rarely in developed countries.
PREDOMINANT AGE:

- Occurs in the second and third decades of life in the developed world.
- In contrast, it affects young children more often in developing countries.

PREDOMINANT SEX: Slightly more prevalent in males than in females because the latter group tend to have better oral hygiene.

RISK FACTORS

- Poor oral hygiene
- Smoking/chewing tobacco
- Alcohol use
- Drug addiction
- Poor socioeconomic status
- Psychological stress
- Preexisting gingivitis
- Lack of sleep
- Malnutrition
- Overcrowding
- Living near livestock
- History of prior NUG
- Recent illness
- Underlying systemic diseases
- Acatalasia
- Various infections such as measles, malaria, and infestation with intestinal parasites
- Trauma
- Immunosuppression:
  1. Dermatomyositis (DM)
  2. Steroid use
  3. HIV/AIDS
  4. Use of chemotherapeutic drugs
  5. Leukemia and other malignancies

ETIOLOGY

- Polymicrobial
- Often caused by both *Fusobacterium* and spirochetes

PATHOGENESIS

- Unknown.
- For the most part, it appears to result from an opportunistic infection in a host with lowered resistance.

CLINICAL FEATURES

- Onset of the disease is usually sudden.
- Severe gingival pain.
- Gingival tissue is inflamed, edematous, friable, and necrotic; the normal pointed interdental papillae are blunted, but there is no loss of attachment.
- Gingival bleeding with little or no provocation.
- Punched out ulcerations are seen along the interdental papillae around the anterior incisors and posterior molars. A grayish-white pseudomembrane often covers these ulcers. These punched out ulcers along the pseudomembrane are pathognomonic of NUG.
- Other features include:
  1. Halitosis
  2. Alteration in taste, such as a metallic flavor
  3. Wooden teeth feeling
  4. Odynophagia
  5. Fever and fatigue
  6. Cervical lymphadenopathy

DIAGNOSIS

- Based on the clinical features
- WBC may be elevated
- Gram stain and aerobic/anaerobic culture
- Dental x-ray or x-ray of face to check on the extent of the disease
- HIV testing is recommended for patients refractory to antibiotic therapy

DIFFERENTIAL DIAGNOSIS

- Gingivitis
- Acute herpetic gingivostomatitis
- Aphthous stomatitis
- Chronic periodontal disease
- Desquamative gingivitis
- Gonococcal and streptococcal gingivostomatitis
- Oral candidiasis
- Ludwig angina
- HIV-associated idiopathic ulcerations

TREATMENT

- Improve oral hygiene by flossing and brushing at least twice a day.
- Improve nutrition and hydrations.
- Eliminate contributing factors such as smoking, alcohol, carbonated beverages, spicy/hot foods, poor nutrition, stress, and so on.
- Antibiotic coverage for 5 to 10 days. Most recommend oral penicillin V 250 to 500 mg orally every 6 to 8 hr and metronidazole 250 to 500 mg orally every 8 hr. Tetracycline is given instead of penicillin in patients allergic to the latter. As an alternative one could give only clindamycin instead of the drug combination of penicillin and metronidazole.
- Rinsing the mouth at least twice a day with warm saline (1/2 teaspoon of salt in 1 cup of water), 0.12% chlorhexidine, or dilute 3% hydrogen peroxide (mixed half and half with water).
- Pain is controlled with oral pain medications and topical application of 2% viscous lidocaine (15 ml oral rinse every 6 to 8 hr as needed) to the inflamed gum.
- Surgical debridement is needed in severe cases.
- Scaling and root planing following the resolution of infection and the acute inflammation.
- At times reconstructive surgery may be needed.

COMPLICATIONS

- Cancrum oris (noma) results when NUG involves the deeper tissue
- Vincent angina from the involvement of tonsils and pharynx
- Necrotizing ulcerative periodontitis
- Loss of teeth
- Periodontal abscess
- Alveolar bone destruction
- Disfigurement
- Cellulitis
- Dehydration/malnutrition

PROGNOSIS

- Dramatic relief of symptoms within 24 hr of initiating antibiotics and supportive treatment is characteristic.
- Risk of recurrence is high.

PEARLS & CONSIDERATIONS

PREVENTION

- Good oral hygiene
- Use of power toothbrush is better than a manual brush
- Good general health including proper nutrition, sleep, and exercise
- Routine dental checks
- Avoidance of smoking and alcohol
- Stress management

PATIENT EDUCATION

Not a communicable disease

AUTHOR: **Hemant K. Satpathy, MD**

Glaucoma, Open-Angle PTG

BASIC INFORMATION

Glaucoma is a chronic degenerative optic neuropathy (or the high potential for such degeneration due to risk factors) in which the neuroretinal rim of the optic nerve becomes progressively thinner, thereby enlarging the optic-nerve cup. The classification of glaucoma is based on the appearance of the iridocorneal angle (open angle vs. narrow or closed angle) and is further subdivided into primary and secondary types. Fig. 1 and Table 1 illustrate the difference between open-angle and narrow-angle glaucoma. Primary open-angle glaucoma can occur with or without elevated intraocular pressure (IOP). Normal tension glaucoma refers to primary open-angle glaucoma without elevated intraocular pressure.

SYNONYMS

Primary open-angle glaucoma (POAG)
Open-angle glaucoma or chronic open-angle glaucoma (OAG, COAG)
Secondary open-angle glaucoma (e.g., pseudoexfoliation, pigment dispersion, trauma, inflammatory)
Ocular hypertension (elevated intraocular pressure with no evidence of optic nerve damage)
Optic nerve cupping, glaucoma suspect

ICD-10CM CODES

H40.10X0	Unspecified open-angle glaucoma, stage unspecified
H40.10X1	Unspecified open-angle glaucoma, mild stage
H40.10X2	Unspecified open-angle glaucoma, moderate stage
H40.10X3	Unspecified open-angle glaucoma, severe stage
H40.10X4	Unspecified open-angle glaucoma, indeterminate stage
H40.11X0	Primary open-angle glaucoma, stage unspecified
H40.11X1	Primary open-angle glaucoma, mild stage
H40.11X2	Primary open-angle glaucoma, moderate stage
H40.11X3	Primary open-angle glaucoma, severe stage
H40.11X4	Primary open-angle glaucoma, indeterminate stage

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Third most common cause of vision loss (75% to 95% of all forms of glaucoma are open angle)

PEAK INCIDENCE:
- Increases after age 40 yr
- Three million cases expected by 2020 because of the rapid increase in aging population

PREVALENCE (IN U.S.):
- Overall prevalence in U.S. population aged >40 yr is estimated to be 1.86%, with 1.57 million white and 398,000 black patients affected. By 2020, we may expect more than 3 million cases in the U.S.
- 150,000 patients have bilateral blindness.
- Prevalence is higher in diabetics, those with high myopia, and older persons.
- More common in African-American population (three times the age-adjusted prevalence than whites). There is a genetic tendency to OAG; multiple genes have been isolated that are associated with development of high IOP and optic nerve damage.

PREDOMINANT AGE:
- Persons >50 yr
- Can occur in 30s and 40s, and juvenile forms are rare

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- High intraocular pressures and/or large optic nerve cup (Fig. E2). Ocular Hypertension Treatment Study results help to delineate important risk factors, including high eye pressure, thin corneal central thickness, age, and visual field results.
- Abnormal visual fields (with advanced glaucoma damage to the optic nerve).
- Open anterior chamber angle—evaluated with gonioscopy at slit lamp
- Figs. E3 and E4 illustrate stages of open-angle glaucoma.
- Since early treatable stages of OAG normally have no symptoms, it's important to have routine eye exams, especially patients with family history and patients over 60 yr.
- Secondary forms of OAG may exhibit ocular findings such as pseudo-exfoliation, pigment dispersion, blood in anterior chamber, inflammation.

ETIOLOGY

- Uncertain hereditary tendency (multifactorial genetics)
- Topical steroids can induce high IOP and cause glaucoma
- Trauma
- Inflammatory (e.g., history of uveitis)
- High-dose oral corticosteroids taken for prolonged periods

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other optic neuropathies (previous retinal vascular disorders, optic nerve pits, or coloboma).
- Physiologic cupping of the optic nerve: The optic nerve may appear similar to glaucoma damage but does not progress. This is followed for any signs of progression.
- Ocular hypertension: IOP is chronically elevated, but not causing optic nerve damage, must monitor closely.
- Secondary glaucoma from inflammation and steroid therapy.
- Trauma

WORKUP

- Comprehensive eye examination
- Intraocular pressure
- Slit lamp examination
- Visual fields
- Gonioscopy: To determine the type of glaucoma (narrow, open, or closed angles)
- Nerve fiber analysis (e.g., OCT, and HRT)
- Corneal thickness (thick central cornea will result in possible overestimation of the true physiologic IOP, and vice versa, so this is

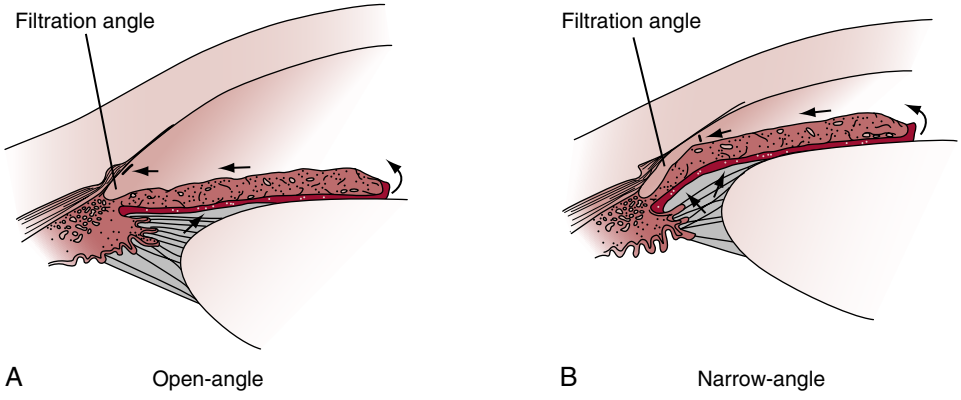

FIG. 1 A, Open-angle glaucoma: Drainage of the aqueous humor becomes obstructed, and impaired flow from the eye leads to gradually increased intraocular pressure. **B,** Narrow-angle glaucoma: When the iris moves forward, as may occur during pupil dilation, the angle is narrowed or even closed. Obstruction of aqueous humor flow leads to angle-closure glaucoma. (From Kaufman DM, Geyer HL, Milstein MJ: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

TABLE 1 Characteristics of Glaucoma

Feature	Primary Open-Angle Glaucoma	Narrow-Angle Glaucoma
Occurrence	85% of all glaucoma cases	15% of all glaucoma cases
Cause	Unclear*	Closed angle prevents aqueous drainage
Age at onset	Variable	50 to 85 yr
Anterior chamber	Usually normal	Shallow
Chamber angle	Normal	Narrow
Symptoms	Usually none Decreased vision, late	Headache Seeing halos around lights Sudden onset of severe eye pain Vomiting during attack
Cupping of disc	Progressive if not treated	After one or more untreated attacks
Visual fields	Peripheral fields are involved early Central involvement is a very late sign	Involvement is a late sign
Ocular pressure	Progressively higher if not medically controlled Late: High	Early: Detected with provocative tests only
Other signs		Fixed, partially dilated pupil Conjunctival injection "Steamy" cornea†
Treatment	Medical Laser surgery	Surgical
Prognosis	Good if recognized early Very dependent on patient compliance	Good

*Thought to be a defect in the trabecular network ultrastructure.
†Like looking through a steamy window.
From Swartz MH: *Textbook of physical diagnosis, history and examination,* ed 7, Philadelphia, 2014, Elsevier.

important information in diagnosis and treatment of OAG)

LABORATORY TESTS

Blood sugar

IMAGING STUDIES

- Optic nerve photography—stereo photographs
- Visual field testing
- Laser scan of nerve fiber layer, OCT, HRT. Rarely, MRI of orbits if the glaucoma findings are atypical or suspicious of other causes of optic nerve atrophy.

Rx TREATMENT

ACUTE GENERAL Rx

- β-Blockers (e.g., timolol) qd to bid depending on individual response to drug.
- Carbonic anhydrase inhibitors (e.g., Diamox 250 mg qid or 500 mg bid).
- Prostaglandin analogues (latanoprost, bimatoprost, travoprost, tafluprost) are commonly used as first-line treatment. They lower intraocular pressure by 25% to 30% by increasing uveoscleral outflow and reducing aqueous production.
- Alpha-2 agonists and cholinergic agonists.
- Hyperosmotic agents (mannitol) in acute treatment (IV).
- Selective laser trabeculoplasty (SLT) may delay or forestall need for second eye drop. The effect may be temporary but the laser can be repeated.

CHRONIC Rx

- At least biannual checks of intraocular pressure and adjustment of medication.
- Surgical trabeculectomy and filter valve surgeries can be considered for glaucoma that progresses (optic nerve changes or visual field progression) despite maximal tolerated medical therapies. Recently, minimally invasive glaucoma surgeries (MIGS) have been advocated for IOP control. Some are performed at the time of cataract procedures and some are independent procedures. The effort is to reduce the risks associated with traditional trabeculectomy.

DISPOSITION

Must be followed by ophthalmologist

REFERRAL

Immediately to ophthalmologist

PEARLS & CONSIDERATIONS

COMMENTS

- Glaucoma is a serious blinding disease that must be monitored professionally by an ophthalmologist. It is mostly asymptomatic until late in the disease when visual problems arise. Even in developed countries half of glaucoma cases are undiagnosed.
- Risk factors that should prompt referral to an ophthalmologist for evaluation of glaucoma are high intraocular pressure, family history of glaucoma, use of systemic or topical corticosteroids, older age, and black race.
- Vision loss from glaucoma cannot be recovered. Early diagnosis and treatment may minimize visual loss.
- Glaucoma is not solely caused by increased intraocular pressure because approximately 20% of patients with glaucoma have normal intraocular pressure. However, high pressure is definitely a risk factor to be considered.

Glaucoma, Primary Angle-Closure PTG

BASIC INFORMATION

DEFINITION

Primary angle-closure glaucoma occurs when elevated intraocular pressure is associated with closure of the filtration angle or obstruction in the circulating pathway of the aqueous humor.

SYNONYMS

Acute glaucoma, angle-closure glaucoma (ACG)
Pupillary block glaucoma
Narrow-angle glaucoma
Angle-closure glaucoma

ICD-10CM CODES

H40.061	Primary angle closure without glaucoma damage, right eye
H40.062	Primary angle closure without glaucoma damage, left eye
H40.063	Primary angle closure without glaucoma damage, bilateral
H40.069	Primary angle closure without glaucoma damage, unspecified eye

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- 2% to 8% of all patients with glaucoma.
- Higher incidence among those with hyperopia, small eyes, dense cataracts, shallow anterior chambers.

PEAK INCIDENCE: Greater >50 yr; high association with hyperopia, cataracts, and eye trauma
PREDOMINANT SEX: Females are affected more often than males.
PREDOMINANT AGE: 50 to 60 yr
GENETICS: Family history is not particularly helpful; far-sighted (hyperopes) individuals with thickening lenses (i.e., cataracts) are often those with angle-closure attacks.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Although angle-closure glaucoma can present with an acute painful crisis associated with blurred vision, more than 75% of patients present with an asymptomatic course with progressive loss of the visual field (similar to that in patients with primary open-angle glaucoma; referred to as intermittent, subacute, or chronic angle closure)
- Hazy cornea
- Narrow angle
- Pain may be present (supraorbital headache is typical)
- Injection of conjunctiva, red eye (often severe limbal conjunctival injection with very high intraocular pressure [IOP])
- Shallow anterior chamber (one can shine a light from the side to perceive the forward position of the iris with narrow AC angles)
- Thick cataract
- Pupil may be mid-dilated and nonreactive to light
- Figs. E1 and E2 illustrate gonioscopy in primary angle-closure glaucoma

ETIOLOGY

- Narrow angles with acute closure: Blockage of circulatory path of the aqueous humor (Fig. E3) causing increase in IOP. ACG (primary angle closure glaucoma) occurs more commonly in eyes with shorter axial length (far-sightedness), shallower anterior chamber, and a relatively larger lens (enlarging cataract).
- Secondary angle-closure glaucoma (more rare) resulting from neovascularization of iris, iris tumors, lens induced, iris scarring, trauma, chronic inflammation with scarring, malignant glaucoma with aqueous misdirection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Open-angle glaucoma: Angle-closure glaucoma is distinguished from open-angle glaucoma by the closure of the angle between the iris and cornea, obstructing outflow of aqueous humor
- High intraocular pressure (normal IOP is usually 8 to 21 mm Hg)
- Optic nerve cupping
- Shallow chamber
- Open-angle glaucoma
- Conjunctivitis
- Corneal disease, keratitis
- Uveitis
- Scleritis
- Allergies
- Contact lens wearing with irritation

WORKUP

Comprehensive eye examination: If one suspects narrow angle or angle closure, avoid pupil dilation, as this may exacerbate the attack.

- Intraocular pressure (with ACG, IOP can be extremely high, >60 mm Hg)
- Gonioscopy for direct visualization of the chamber angle
- Slit lamp examination
- Visual field examination
- Laser scan of nerve fiber layer and optic nerve, optical coherence tomography (OCT)
- Optic nerve evaluation
- Anterior chamber depth

LABORATORY TESTS

- Blood sugar and complete blood count (if diabetes or inflammatory disease is suspected)
- Visual field
- Nerve fiber analysis, OCT, Heidelberg retinal tomography

IMAGING STUDIES

- Fundus photography (optic nerve photos)—very helpful for comparing changes in optic nerve shape
- Fluorescein angiography for neovascular disease such as diabetic retinopathy, retinal vein occlusions
- Ultrasound biomicroscopy and anterior OCT can show relationships of anterior eye structures

TREATMENT

The goal of treatment is to acutely lower pressure on the eye and keep it down.

NONPHARMACOLOGIC THERAPY

Laser iridotomy early in disease process

ACUTE GENERAL Rx

- IV mannitol
- Pilocarpine
- β-Blockers
- Diamox
- Laser iridotomy
- Anterior chamber paracentesis (as emergency treatment)

CHRONIC Rx

- Iridotomy: When there is an adequate peripheral hole in the iris, the chance for future angle closure is usually eliminated unless there are rare other angle anomalies (i.e., plateau iris or peripheral synechiae).
- Lens removal (cataract extraction) can also eliminate the possibility of ACG.
- Trabeculectomy and filter valve procedures for nonresponsive cases.
- Other laser procedures, such as gonioplasty for atypical angle closures.

DISPOSITION

Refer to ophthalmologist immediately.

REFERRAL

If acute angle-closure episode is suspected, should refer emergently to ophthalmologist.

PEARLS & CONSIDERATIONS

COMMENTS

- Do not use antihistamines or vasodilators with narrow-angle glaucoma.
- After iridotomy, the majority of patients will be totally cured and will need no further medication and have no visual loss.
- Lower socioeconomic status and higher levels of social deprivation are risk factors for delayed detection and probable worse outcomes in glaucoma.
- Risk factors that should prompt referral to an ophthalmologist for evaluation of glaucoma are high intraocular pressure, family history of glaucoma, use of systemic or topical corticosteroids, older age, and black race.
- Glaucoma is undiagnosed in 9 out of 10 affected people worldwide and is undiagnosed in 50% of those in developed countries.
- Angle closure has become rarer because most people have cataract extractions at an earlier stage than in the past.

Glenohumeral Dislocation

BASIC INFORMATION

DEFINITION

Glenohumeral dislocation occurs when the humeral head exceeds its physiologic limitations, causing it to translate beyond the glenoid rim. It often requires some form of reduction in order to relocate the humeral head. Lesser events that are self-limited are termed *subluxation* or *subjective instability.* During these events, the humeral head translates too, but not past the glenoid rim.

Often, the cause of dislocation is traumatic, with the most common direction of humeral head translation being anteriorly and inferiorly. Some anterior dislocations may cause a tear of the anteroinferior glenoid labrum (Bankart lesion). Less commonly the head may dislocate posteriorly, such as during seizures or electrocution.

Multidirectional instability predisposes patients to dislocation and is present in a small number of patients. Frequent subluxations or dislocations may occur in multiple directions and result in excessive joint laxity. They may occur with minimal trauma and are often bilateral.

ICD-10CM CODES	
M24.419	Recurrent dislocation, unspecified shoulder
M24.819	Other specific joint derangements of unspecified shoulder, not elsewhere classified
S43.016A	Anterior dislocation of unspecified humerus, initial encounter
S43.026A	Posterior dislocation of unspecified humerus, initial encounter
S43.036A	Inferior dislocation of unspecified humerus, initial encounter

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Traumatic:

- The arm is held in external rotation with anterior dislocation and internal rotation with posterior dislocation.
- Slight movement is possible without pain.
- The acromion may appear more prominent, and there may be an absence of the normal "fullness" beneath the acromion.
- Status of the axillary nerve must always be checked before and after reduction (sensation to the lateral shoulder and ability to gently activate the deltoid).
- Fractures of the humeral head or glenoid rim may occur and predispose patients to future instability and dislocation events.

Multidirectional:

- Often present after minimal trauma or with recurrent episodes of "giving out," weakness, and popping.
- Sulcus sign may be positive (as the arm is pulled inferiorly with the patient upright, an indentation forms between the acromion and humeral head, indicating excessive inferior movement of the head).
- Other signs of generalized joint laxity may be present, such as elbow hyperextension, extension of the small finger metacarpophalangeal joint >90 degrees, or flexion of the thumb down to the volar forearm (Beighton criteria).

ETIOLOGY

- Anterior: Due to trauma, often with the arm abducted and externally rotated
- Posterior: Often secondary to seizure or electrical shock
- Multidirectional: Secondary to generalized joint laxity

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Proximal humerus fracture
- Grade 3 or greater acromioclavicular (AC) joint injury: Presents with pain and prominent AC joint

IMAGING STUDIES

- Acute shoulder injury: True anteroposterior (AP) (aimed 15 degrees across the body for a perpendicular view of the glenohumeral joint), scapular "Y" view, and an axillary lateral
  1. Internal/external rotation variations in the true AP image may reveal bony injury to the proximal humerus.
- CT: Useful to evaluate fractures of the glenoid and/or humerus. May include contrast arthrogram to evaluate labrum and rotator cuff
- MRI: Useful to evaluate soft tissue only, including labral injury or rotator cuff tear

TREATMENT

- Reduction of the acute dislocation by gentle distal traction in the relaxed patient should be followed by brief immobilization with a sling (less than 1 wk for simple dislocations).
- Posterior dislocations, inferior dislocations, or fracture-dislocations should be reduced by an experienced practitioner.
- Gentle limited range-of-motion exercises as pain subsides followed by strengthening exercises at 2 wk.

DISPOSITION

- Recurrence of anterior dislocation is common in the young population; patients under 30 should be referred to an orthopedist for further evaluation.
- Primary dislocations in patients >40 yr old are not generally complicated by recurrence but may result in shoulder stiffness and associated rotator cuff tears.
- There is an almost 100% recurrence after the third dislocation.

REFERRAL

Surgical reconstruction may be required in patients with recurrent dislocations.

PEARLS & CONSIDERATIONS

COMMENTS

- X-rays in two orthogonal planes are always indicated to confirm dislocation or reduction. A single radiograph is never acceptable.
- It is important to know if there was an injury involved in the first episode and if a radiograph was taken to determine direction of the dislocation.
- Up to 50% of posterior dislocations are missed by the first examiner, usually the result of an inadequate lateral radiograph of the glenohumeral joint.
- "Voluntary" dislocators should typically be treated nonsurgically.
- Sports activities may be resumed when there is pain-free full motion with normal strength.
- Multidirectional instabilities are usually treated nonsurgically with strengthening exercises, and rehabilitation.
- Dislocations in either direction are occasionally overlooked. If the injury is over 2 to 4 wk old, enough tissue healing will have occurred to make closed reduction nearly impossible. Open surgical reduction may then be needed.

BASIC INFORMATION

DEFINITION

Glossitis is an inflammation of the tongue that can lead to loss of filiform papillae.

ICD-10CM CODES
K14.0 Glossitis
K14.2 Median rhomboid glossitis

EPIDEMIOLOGY & DEMOGRAPHICS

Glossitis is seen more frequently in patients of lower socioeconomic status, malnourished patients, alcoholics, smokers, elderly patients, immunocompromised patients, and patients with dentures.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The appearance of the tongue varies depending on the etiology of the glossitis (Fig. E1). Loss of filiform papillae results in a red, smooth-surfaced tongue.
- The tongue may appear pale in patients with significant anemia.
- Pain and swelling of the tongue may be present when glossitis is associated with infections, trauma, or lichen planus.
- Ulcerations may be present in patients with herpetic glossitis, pemphigus, or streptococcal infection.
- Excessive use of mouthwash may result in a "hairy" appearance of the tongue (Fig. E2).

ETIOLOGY

- Nutritional deficiencies (vitamin E, riboflavin, niacin, vitamin B_{12}, iron)
- Infections (viral, candidiasis, tuberculosis, syphilis)
- Trauma (generally caused by poorly fitting dentures)
- Irritation of the tongue from toothpaste, medications, alcohol, tobacco, citrus
- Lichen planus, pemphigus vulgaris, erythema multiforme
- Neoplasms

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infections
- Use of chemical irritants
- Neoplasms
- Skin disorders (e.g., Behçet syndrome, erythema multiforme)

WORKUP

- Laboratory evaluation to exclude infectious processes, vitamin deficiencies, and systemic disorders
- Biopsy of lesion only when there is no response to treatment

LABORATORY TESTS

- Complete blood count: Decreased hemoglobin and hematocrit, low mean corpuscular volume (MCV) (iron-deficiency anemia), elevated MCV (vitamin B_{12} deficiency)
- Vitamin B_{12} level
- 10% potassium hydroxide (KOH) scrapings in patients with white patches suspect for candidiasis

TREATMENT

NONPHARMACOLOGIC THERAPY

Avoidance of primary irritants such as hot foods, spices, tobacco, and alcohol

ACUTE GENERAL Rx

Treatment varies with the etiology of the glossitis.

- Malnutrition with avitaminosis: Multivitamins
- Candidiasis: Fuconazole 200 mg on day 1, then 100 mg/day for at least 2 wk or nystatin 400,000 U suspension qid for 10 days or 200,000 pastilles dissolved slowly in the mouth 4 to 5 times qd for 10 to 14 days
- Painful oral lesions: Rinsing of the mouth with 2% lidocaine viscous, 1 to 2 tablespoons q4h prn; triamcinolone 0.1% applied to painful ulcers prn for symptomatic relief

CHRONIC Rx

- Lifestyle changes with elimination of tobacco, alcohol, and other primary irritants
- Dental evaluation for correction of ill-fitting dentures
- Correction of associated metabolic abnormalities such as hyperglycemia from diabetes mellitus

DISPOSITION

Most patients experience prompt improvement with identification and treatment of the cause of the glossitis.

REFERRAL

Surgical referral for biopsy of solitary lesions unresponsive to treatment to rule out neoplasm.

PEARLS & CONSIDERATIONS

COMMENTS

If the primary cause of glossitis is not identified or cannot be corrected, enteric nutritional replacement therapy should be considered in malnourished patients.

BASIC INFORMATION

DEFINITION

Gonorrhea is a sexually transmitted bacterial infection with a predilection for columnar and transitional epithelial cells. It commonly manifests as urethritis, cervicitis, or salpingitis. Infection may be asymptomatic. It differs between males and females in course, severity, and ease of recognition.

SYNONYMS

Gonococcal urethritis
Gonococcal vulvovaginitis
Gonococcal cervicitis
Gonococcal bartholinitis
GC

ICD-10CM CODES

A54.9	Gonococcal infection, unspecified
O98.211	Gonorrhea complicating pregnancy, first trimester
O98.212	Gonorrhea complicating pregnancy, second trimester
O98.213	Gonorrhea complicating pregnancy, third trimester
O98.219	Gonorrhea complicating pregnancy, unspecified trimester
O98.22	Gonorrhea complicating childbirth
O98.23	Gonorrhea complicating the puerperium
A54.03	Gonococcal cervicitis, unspecified
A54.00	Gonococcal infection of lower genitourinary tract, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- The disease is common worldwide, affects both sexes and all ages, especially younger adults; highest incidence is in inner-city areas. Per CDC reports, approximately 470,000 new cases were found in the U.S. in 2016 with over 60% found in metropolitan statistical centers. Gonorrhea is the second most commonly reported communicable disease.
- Asymptomatic anterior urethral carriage may occur in 12% to 50% of cases in men.
- Asymptomatic in 50% to 80% of cases in women. Most common dissemination is by mucosal passage to fallopian tubes, resulting in pelvic inflammatory disease (PID) in 10% to 15% of infected women. Hematogenous spread may result in septic arthritis and skin lesions. Conjunctivitis rarely occurs, but may result in blindness if not rapidly treated. Infection can occur in both men and women in oropharynx and anorectally.
- The World Health Organization (WHO) reports that there were 78 million new cases of gonorrhea worldwide among adults in 2012.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Males: Purulent discharge from anterior urethra (Fig. E1), with dysuria appearing 2 to 7 days after infecting exposure. May have rectal infection causing pruritus, tenesmus, and discharge, or may be asymptomatic.
- Females: Initial urethritis or cervicitis may occur a few days after exposure, frequently mild. Infections may be asymptomatic or may not produce recognizable symptoms until complications have occurred. In approximately 20% of cases uterine invasion occurs after menstrual period with signs and symptoms of endometritis, salpingitis, or pelvic peritonitis. The patient may have purulent discharge or inflamed Skene or Bartholin glands.
- Classic presentation of acute gonococcal PID is fever, abdominal and adnexal tenderness, and, often, absence of purulent discharge. Physical examination may be normal if asymptomatic. Disseminated gonococcal infection (DGI) may manifest with petechial or pustular acral skin lesions (Fig. E2), asymmetric polyarthralgia, tenosynovitis, or oligoarticular septic arthritis. The infection is occasionally complicated by perihepatitis and, rarely, endocarditis or meningitis.

ETIOLOGY

- *Neisseria gonorrhoeae* is also known as gonococcus. Plasmids coding for β-lactamase render some strains resistant to penicillin or tetracycline. There is an increasing frequency of chromosomally mediated resistance to penicillin, tetracycline, fluoroquinolones, and cefoxitin. In the Far East, high-level resistance to spectinomycin is endemic.
- There is a rising number of cases of quinolone-resistant *N. gonorrhoeae* worldwide, with the expected number to rise in the U.S. from importation.
- Men who have sex with men are vulnerable to the emerging threat of antimicrobial-resistant *N. gonorrhoeae.*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nongonococcal urethritis (NGU)
- Nongonococcal mucopurulent cervicitis
- *Chlamydia trachomatis*

WORKUP

Diagnosis depends on bacteriologic investigation. Culture and nucleic acid amplification tests (NAAT) are available for the detection of genitourinary infection with *N. gonorrhoeae.*

- NAATs are preferred testing modalities for the detection of genitourinary infection with *N. gonorrhoeae.* The performance of NAATs with respect to overall sensitivity, specificity, and ease of specimen transport is better than that of any of the other tests available for the diagnosis of gonococcal infections. NAATs should be used to detect gonorrhea except in cases of child sexual assault involving boys and rectal and oropharyngeal infections in prepubescent girls. When evaluating a potential gonorrhea treatment failure, case culture and susceptibility testing might be required. NAATs allow testing of the widest variety of specimen types, including endocervical swabs, vaginal swabs, urethral swabs (men), and urine (from both men and women).
- Culture: Gonorrhea culture on Thayer-Martin medium (organism is fastidious; requires aerobic conditions with increased carbon dioxide atmosphere; incubate ASAP). Culture has a sensitivity of 95% or more for urethral specimens from men with symptomatic urethritis and 80% to 90% for endocervical infection in women. Gram-negative intracellular diplococci are diagnostic in male urethral smears (Fig. E3). There is a false-negative rate of 60% to 70% in female cervical or urethral smears.
  1. Concomitant serologic testing for syphilis for all patients
  2. Concomitant *Chlamydia* testing for all patients
  3. Offer of HIV testing and counseling to all patients

LABORATORY TESTS

- First-catch urine (or genital swab) sample NAAT is the preferred screening and diagnostic test for gonorrhea. These tests have largely replaced culture in many settings where persons are screened for asymptomatic genital infection. They are not more sensitive than culture for detecting *N. gonorrhoeae* in cervical or urethral specimen; however, they have specificities >99% and retain sensitivity when used to test voided urine or self-collected vaginal swabs.
- Gonorrhea culture on Thayer-Martin medium (organism is fastidious; requires aerobic conditions with increased carbon dioxide atmosphere; incubate ASAP). Culture has a sensitivity of 95% or more for urethral specimens from men with symptomatic urethritis and 80% to 90% for endocervical infection in women.
- Nonamplified DNA probe tests are less sensitive than culture or NAATs and are not useful in the diagnosis of rectal or pharyngeal infection or for testing urine; however, they are inexpensive, readily available and offered in many laboratories in combination assays for *C. trachomatis.*
- Concomitant serologic testing for syphilis on all patients.
- Concomitant *Chlamydia* testing on all patients.
- Offer of HIV testing and counseling to all patients.

TREATMENT

ACUTE GENERAL Rx

Uncomplicated infections of the cervix, urethra, and rectum. Critical for the practitioner to know local resistance characteristics to best treat the patient:

- Ceftriaxone 250 mg IM × 1 dose *plus* azithromycin 1 g PO single dose. Doxycycline 100 mg PO bid for 7 days can be substituted for

azithromycin in patients with azithromycin allergy.

Alternative regimens if ceftriaxone is not available:

- Ceftizoxime, cefoxitin with probenecid, and cefotaxime. None of these injectable cephalosporins offer any advantage over ceftriaxone.
- Cefixime 400 mg PO × 1 dose *plus* azithromycin 1 g orally single dose. Doxycycline 100 mg PO bid for 7 days can be substituted for azithromycin in patients with azithromycin allergy.
- If the patient has severe cephalosporin allergy, then azithromycin 2 g PO single dose *plus* single-dose gemifloxacin 320 mg PO or gentamicin 240 mg IM.
- A test-of-cure is not needed for persons who receive a diagnosis of uncomplicated urogenital or rectal gonorrhea who are treated with any of the recommended or alternative regimens.

Uncomplicated gonococcal infections of the pharynx:

- Ceftriaxone 250 mg IM × 1 dose *plus* azithromycin 1 g PO single dose. Doxycycline 100 mg PO bid for 7 days can be substituted for azithromycin in patients with azithromycin allergy.
- Treatment of the cephalosporin-allergic patient: Oral azithromycin 2 g *plus* single dose gemifloxacin 320 mg PO *or* 240 mg IM of gentamicin is effective.
- Any person with pharyngeal gonorrhea who is treated with an alternative regimen should return 14 days after treatment for a test-of-cure using either culture or NAAT.

Treatment of arthritis and arthritis-dermatitis syndrome:

- Recommended regimen: Ceftriaxone 1 g IM or IV every 24 hours plus azithromycin 1 g orally as a single dose.
- Alternative regimens: Cefotaxime 1 g IV every 8 hours or ceftizoxime 1 g IV every 8 hours *plus* azithromycin 1 g orally in a single dose.

Pregnancy

- Pregnant women infected with *N. gonorrhoeae* should be treated with dual therapy consisting of ceftriaxone 250 mg in a single IM dose or azithromycin 1 g PO as a single dose. When cephalosporin allergy or other considerations preclude treatment and spectinomycin is not available, consultation with an ID specialist is recommended.

DISPOSITION

- To reduce development of drug resistance, reculture should be done for patients who show continued symptoms despite treatment. These patients should be tested with a culture-based gonorrhea test that can detect antibiotic resistance.
- All sexual partners should be identified, examined, tested, and receive presumptive treatment.
- Patients should be counseled to avoid unprotected intercourse with partners for 1 wk after all partners have completed treatment.

REFERRAL

PID requiring hospitalization, disseminated gonococcal infection

PEARLS & CONSIDERATIONS

COMMENTS

- This is a reportable disease.
- The proportion of gonorrhea cases in heterosexual men who are fluoroquinolone resistant (QRNG) has reached 6.7%, an elevenfold increase from 0.6% in 2001. Fluoroquinolone antibiotics are no longer recommended to treat gonorrhea in the U.S.
- The use of azithromycin as the second antimicrobial is preferred over doxycycline due to the high prevalence of tetracycline resistance.
- The U.S. Preventive Services Task Force (USPSTF) recommends screening for gonorrhea in sexually active females younger than 25 yrs and in older women who are at increased risk for infection (multiple partners, new partner, partner who has concurrent partners). The USPSTF also concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for gonorrhea in men.
- High-intensity counseling on sexual risk reduction has been shown to reduce sexually transmitted infections (STIs) in primary care and related settings.

BASIC INFORMATION

DEFINITION

Anti-glomerular basement membrane disease (anti-GBM disease), also known as Goodpasture disease, is a rare, autoimmune, small-vessel vasculitis affecting blood vessels of the lungs and kidneys that results in a pulmonary-renal syndrome. A pulmonary-renal syndrome is defined as the coexistence of pulmonary alveolar hemorrhage (i.e., triad of hemoptysis, diffuse alveolar infiltrates, and anemia) and acute kidney injury (AKI) from rapidly progressive glomerulonephritis (RPGN). Notably, a pulmonary-renal syndrome may affect only the kidneys (AKI and RPGN) or kidneys and lungs simultaneously. Rarely, only the lungs are involved.

SYNONYMS

Anti-glomerular basement membrane disease
Goodpasture syndrome

ICD-10CM CODES

N01.7	Rapidly progressive nephritic syndrome with diffuse crescentic glomerulonephritis
N00.7	Acute nephritic syndrome with diffuse crescentic glomerulonephritis

EPIDEMIOLOGY & DEMOGRAPHICS

- Anti-GBM disease has a bimodal age distribution, predominantly affecting young, white, male smokers, and, next most commonly, affecting older adults (>50 yr old, women more than men)
- Goodpasture disease accounts for 5% to 15% of all cases of RPGN
- HLA-DR2 locus is positive in 80% of patients.
- Approximately 20% to 40% of patients with anti-GBM antibody have positive antineutrophil cytoplasmic auto-antibodies (ANCAs)
- Anti-GBM disease can also occur with other glomerular diseases, such as ANCA- vasculitis, lupus, and membranous nephropathy
- Anti-GBM disease may occur posttransplant due to newly formed antibodies in up to 5% of patients with Alport disease who undergo kidney transplantation
- Secondary anti-GBM disease may occur in patients treated with immunomodulatory agents or in other autoimmune diseases, including multiple sclerosis, rheumatoid arthritis, celiac disease, ulcerative colitis, and infective endocarditis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Dyspnea, cough, hemoptysis
- Skin pallor, fever, arthralgias (may be mild or absent at the time of initial presentation)
- Hematuria may be noted
- Frothy urine due to proteinuria, although nephrotic syndrome is uncommon

ETIOLOGY

Anti-GBM disease is caused by autoantibodies directed against the alpha-3 chain of type IV collagen, a primary component of the glomerular basement membrane (GBM). The presentation of the disease is due to the distribution of the antigen. Antibody deposition leads to immune cell- and complement-mediated tissue inflammatory damage resulting in pulmonary hemorrhage and glomerulonephritis. With appropriate treatment, there is eventual decline in antibody titers, and relapse with antibody production is rare.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Granulomatosis with polyangiitis
- Systemic lupus erythematosus
- Eosinophilic granulomatosis with polyangiitis (eGPA), formerly Churg-Strauss syndrome
- Essential mixed cryoglobulinemia
- Idiopathic rapidly progressive glomerulonephritis
- Drug-induced renal pulmonary disease (e.g., penicillamine)

WORKUP

Laboratory and clinical evaluation, diagnostic imaging, and kidney biopsy

LABORATORY & CLINICAL TESTS

- Serum anti-GBM antibodies (commercial enzyme-linked immunosorbent assay (ELISA) has 95% sensitivity and 95% to 99% specificity)
- Normal serum complement (C3 and C4) levels
- Absence of circulating immune complexes, antineutrophil cytoplasmic antibodies (except with overlap), and cryoglobulins
- Urinalysis with microscopic hematuria, proteinuria, and red blood cell casts
- Urine protein–to–creatinine ratio to quantify proteinuria
- Elevated blood urea nitrogen and creatinine
- Immunofluorescence studies of kidney biopsy specimens with anti-GBM antibody demonstrate linear staining pattern, often with C3 deposition
- Complete blood count and serum iron studies demonstrate iron-deficiency anemia from urinary and pulmonary blood losses
- Bronchoalveolar lavage may demonstrate presence of alveolar hemorrhage and exclude an infection

IMAGING STUDIES

Chest radiograph with airspace disease composed of alveolar infiltrates or evidence of pulmonary hemorrhage (Fig. E1)

TREATMENT

ACUTE GENERAL Rx

- Plasmapheresis with albumin replacement for 1 to 2 wk (fresh frozen plasma used if bleeding risk present), with immunosuppression typically consisting of prednisone (1 mg/kg per day) and oral cyclophosphamide (2 mg/kg per day). Intravenous cyclophosphamide has been used at some institutions. Rituximab has not been studied in trials but is used in patients who may not be good candidates for cyclophosphamide.
- Hemodialysis if kidney failure occurs.
- Factors influencing treatment decisions in Goodpasture disease are described in Table E1.

DISPOSITION

Life-threatening pulmonary hemorrhage and irreversible glomerular damage are major causes of death.

REFERRAL

- Referral for kidney biopsy to guide management
- Consider kidney transplantation in patients with end-stage renal disease

BASIC INFORMATION

DEFINITION

Gout is a term used to refer to a group of disease states caused by tissue deposition of monosodium urate due to prolonged hyperuricemia. Clinical manifestations of gout include acute and chronic arthritis, soft tissue inflammation, tophus formation, gouty nephropathy, and nephrolithiasis. Untreated hyperuricemia in patients with gout may lead to chronic destructive deforming arthritis.

ICD-10CM CODES

M10	Gout
M10.0	Idiopathic gout
M10.1	Lead-induced gout
M10.2	Drug-induced gout
M10.3	Gout due to impairment of renal function
M10.4	Other secondary gout
M10.9	Gout, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Self-reported prevalence in the U.S. is estimated at 3.9% of adults.
PREDOMINANT SEX: Male:female ratio ~4:1
PREDOMINANT AGE: 30 to 50 yr in men; older than 60 yr in women

ETIOLOGY

- Gout is induced by inflammation from monosodium urate (MSU) crystal deposition. The primary risk factor for MSU deposition is hyperuricemia, though local factors such as temperature, pH, and mechanical stress may play a role. Fig. E1 illustrates the pathophysiology of gout.
- Hyperuricemia and gout develop from excessive uric acid production, a decrease in the renal excretion of uric acid, or both.
- Primary hyperuricemia results from an inborn error of metabolism and may be attributed to several biochemical defects.
- Secondary hyperuricemia may develop as a complication of acquired disorders (e.g., leukemia) or as a result of the use of certain drugs (e.g., diuretics). Consumption of alcohol, especially beer, increases the risk of gout, and fructose-rich beverage intake is associated with hyperuricemia. Gout promoters and inhibitors are summarized in Table 1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

ACUTE GOUT:

- Rapid onset of pain and swelling and erythema of a distal joint and/or periarticular soft tissue. Box 1 summarizes clinical pearls in acute gout attacks.
- May present as monoarthritis of any joint. Acute gout of the first metatarsophalangeal (MTP) joint is known as *podagra.*
- 10% to 15% of attacks are polyarticular.
- Spontaneous resolution occurs over days to wks.

CHRONIC TOPHACEOUS GOUT (FIG. E2):

- Insidious onset of painless arthritis and soft tissue swelling
- Distal small joints characteristic
- May be confused with nodal osteoarthritis
- Box 2 summarizes clinical pearls in chronic gout

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS OF ACUTE GOUT

- Septic arthritis, cellulitis
- Pseudogout, calcium pyrophosphate crystal deposition disease
- Trauma

DIFFERENTIAL DIAGNOSIS OF CHRONIC GOUT

- Osteoarthritis (especially nodal OA in women)
- Rheumatoid arthritis
- Psoriatic arthritis

Section II describes the differential diagnosis of acute monoarticular and oligoarticular arthritis.

WORKUP

Arthrocentesis and examination of synovial fluid

LABORATORY TESTS

- Uric acid: All patients with gout are hyperuricemic at some time, but during an acute attack the serum uric acid may be normal or low.
- Synovial aspirate: Usually cloudy and markedly inflammatory in nature. Urate crystals in fluid are needle shaped and strongly negatively birefringent under polarized microscopy (Fig. E3).
- CBC: Neutrophilic leukocytosis often present.
- Inflammatory markers: ESR and CRP often elevated.

IMAGING STUDIES

- Plain radiography for diagnosis and evaluation. No typical findings in early gouty arthritis, but late disease is associated with characteristic punched-out marginal erosions (Fig. E4) and overhanging edges.
- Musculoskeletal ultrasound has been shown to be an effective means of detecting monosodium urate crystal deposition. Ultrasound can differentiate urate crystals that are found on the surface of articular cartilage from CPPD crystals that are seen within the substance of the cartilage (Fig. E5). Double contour sign can be seen.

TREATMENT

TREATMENT OPTIONS FOR ACUTE GOUT (TABLE 2)

- Nonsteroidal antiinflammatory medication (see Table 3).
  1. Indomethacin 75 mg bid
  2. Ibuprofen 800 mg tid
  3. Naproxen 500 mg bid
  4. Celecoxib 20 mg bid
- Low-dose colchicine (less toxic, as effective as traditional high-dose colchicine): 1.2 mg PO, followed by 0.6 mg PO 1 h later, then 0.6 mg daily or bid. Dose for renal function.
- Intraarticular corticosteroid injection (treatment of choice for monoarticular large joint attack): Triamcinolone acetonide 40 mg or equivalent for knee.
- Systemic corticosteroid therapy: prednisone 40 mg PO for 3 days, then taper over 10 days (effective and safe, but evidence is lacking).

TABLE 1 Gout Promoters and Inhibitors*

Crystal formation	Seed nucleus (particulate) Immunoglobulin Phagocytes Low temperature Low pH Cation concentration Intraarticular dehydration Other (unknown) macromolecules
Triggering the acute flare (local factors)	Rapid change in urate level Microcrystal release IgG coat (apolipoproteins B, E inhibitory) Complement activation (classical, alternate, MAC) Inflammasome activation Cytokine and chemokine release Endothelial activation (e-selectin, ICAM-1, VCAM-1) Local trauma?
Presence of susceptible phagocytes, mast cells (systemic events)	Surgery, trauma Infections, other intercurrent systemic illness Alcohol, dietary intake Drugs that raise or lower circulating urate level

*A diverse array of proteins and other mediators have been identified on the surfaces of urate crystals. In addition to their proinflammatory effect through opsonizing existing crystals, immunoglobulin M (IgM) and immunoglobulin G (IgG) antibodies may promote crystal formation by providing a stable molecular platform for crystal nucleation and growth. Apolipoproteins are the best characterized of the antiinflammatory molecules that coat crystals. The characteristics of the phagocytes encountering the crystals may be crucial; macrophages that are more differentiated are less likely to elicit proinflammatory cytokines.

ICAM-1, Intercellular adhesion molecule 1; *Ig,* immunoglobulin; *MAC,* membrane attack complex; *VCAM-1,* vascular cell adhesion molecule 1.

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BOX 1 Acute Gout: Clinical Pearls

- Abrupt and rapid onset
- Maximal symptom intensity at 8-12 hours
- Attacks often come on at night or early morning
- Most commonly monoarticular in men during first attack
- Metatarsophalangeal joint is first affected in 50% of cases; other commonly affected joints: ankle, heel, knee, wrists, and hands
- Joints are red, hot, swollen, and exquisitely tender
- Attacks resolve within days to wks without treatment

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BOX 2 Chronic Gout: Clinical Pearls

- Pattern of symptoms changes: Time between attacks shortens; more joints may be involved
- Tophaceous disease may result in a destructive arthropathy
- Tophaceous deposits may be bothersome and cause marked reduction in quality of life
- Increased risk for nephrolithiasis
- Associated with comorbidities such as metabolic syndrome, diabetes mellitus, chronic kidney disease, cardiovascular disease, hyperlipidemia, and obesity

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

TREATMENT OF HYPERURICEMIA IN PATIENTS WITH GOUT

The American College of Rheumatology and most international rheumatology guidelines recommend that every patient with gout who has tophi, more than two attacks of gout per yr, chronic kidney disease, or nephrolithiasis be treated with pharmacologic urate-lowering therapy. Serum uric acid should be monitored on a regular basis and urate-lowering therapy intensified until a target of less than 6 mg/dl is reached. In most cases, urate-lowering therapy should be continued for life. Fig. 6 summarizes pharmacologic serum urate–lowering treatment.

The American College of Physicians Guidelines recommends a more conservative approach based on recurrence of symptoms. These guidelines have been criticized as ignoring the progressive nature of gout and perpetuating the well-documented underutilization and under-dosing of urate-lowering therapy.

NONPHARMACOLOGIC THERAPY

Lifestyle and dietary modification should always be a component of therapy for patients with gout, but this is rarely effective without concomitant pharmacologic urate-lowering therapy, as dietary modification can lower uric acid only about 1 mg/dl. Recommendations include reducing ingestion of red meat, kidney, liver, yeast extract, shellfish, and overall protein along with restricting alcohol intake. Discontinuation of diuretic therapy may help lower serum uric acid.

PHARMACOLOGIC TREATMENT OF SYMPTOMATIC HYPERURICEMIA

ALLOPURINOL: Allopurinol is very effective and safe when used properly. Correct dosing and patient compliance are essential elements in the prevention of erosive and tophaceous gout. Patients with renal insufficiency are at increased risk for allopurinol hypersensitivity, which manifests as fever, rash, and hepatitis occurring most commonly in the first 3 mo of therapy. The rash may progress to life-threatening toxic epidermal necrolysis if not recognized early.

Traditionally, therapy with allopurinol is initiated several wks after the acute attack has resolved. However, initiation of allopurinol at presentation may improve long-term compliance without reducing the efficacy of acute treatment. The initial dose should be low (≤100 mg/day depending on creatinine clearance) in patients with renal insufficiency and those with very high uric acid levels. High initial doses are associated with increased incidence of allopurinol hypersensitivity. The serum uric acid should be reevaluated after 4 to 6 wk of therapy, and the allopurinol dose adjusted to reduce the serum uric acid to less than 6 mg/dl. The most common therapeutic dosage of allopurinol is 300 mg/day, but dose may be increased by 50 to 100 mg every 2 to 3 wk until the target serum uric acid level is achieved. There is evidence that increasing allopurinol doses in patients with renal insufficiency does not result in significant toxicity, but concurrent use with statins and colchicine is associated with a higher incidence of adverse effects. Some authors have reported using doses as high as 800 mg daily without excess toxicity. It is recommended that patients of Han Chinese, Thai, and Korean ancestry be tested for HLA-B*5801 before initiating allopurinol as these individuals are at high risk of allopurinol hypersensitivity if this allele is present.

FEBUXOSTAT: Febuxostat is a xanthine oxidase inhibitor that has been shown to be more potent than allopurinol 300 mg daily for reducing serum uric acid. The chemical structure of febuxostat is different from allopurinol, making cross-reactive allergy unlikely. The metabolism of febuxostat is primarily hepatic, which obviates the need for dose adjustments due to renal insufficiency. Some cases of hepatic toxicity have been reported, and it is recommended that liver function tests be monitored. Febuxostat may help preserve renal function in patients with chronic kidney disease (CKD) but has not been tested in patients with severe renal failure.

The primary indication for febuxostat is demonstrated allergy to allopurinol. The cost of febuxostat may be as much as 40 times that of allopurinol, and there is some evidence suggesting that febuxostat may be associated with higher cardiovascular and all-cause mortality than allopurinol in patients with cardiovascular risk factors. In 2019, the FDA added a boxed warning for increased risk of death with febuxostat.

PROBENECID: Uricosuric agents may be used in patients with good renal function and urinary uric acid less than 600 mg in a 24-h collection. Probenecid can be used in patients with intolerance to xanthene-oxidase inhibitors. Compliance is poor due to the necessity of taking the drug more often than once daily.

LESINURAD: Lesinurad is a URAT1 and OAT4 inhibitor approved by the FDA in 2015 for gout-associated hyperuricemia unresponsive to xanthine oxidase inhibitor monotherapy, to be taken in combination with a xanthene oxidase inhibitor. This drug was withdrawn in 2019 because of business-related reasons without safety concerns noted.

PEGLOTICASE: Intravenous PEGylated uricase is FDA approved for treatment of severe refractory tophaceous gout. It is a PEGylated recombinant mammalian uricase that rapidly degrades urate when given intravenously. Use is limited by very high cost and potential toxicities, including frequent gout flares and anaphylaxis. Rasburicase is a nonpegylated uricase used in tumor lysis syndrome and is not indicated for gout treatment.

PATIENT & FAMILY EDUCATION

It is essential that patients, families, physicians, and other members of the health care team appreciate the importance of compliance with a daily allopurinol regimen if recurrent flares and progression to chronic arthritis and tophi are to be avoided. Allopurinol should be discontinued only for symptoms suggesting hypersensitivity; otherwise it should be continued during flares, medical illnesses, and surgical procedures.

REFERRAL

- Rheumatologist if diagnosis is not clear or therapy is complicated
- Podiatrist for management of pedal complications

PEARLS & CONSIDERATIONS

- The interleukin-1 receptor antagonist anakinra (Kineret) is an effective off-label agent for treatment of gout in complex patients with contraindications to standard therapies.
- Do not stop allopurinol during hospitalizations, surgery, or acute attacks unless there is evidence of drug allergy. The dosage of allopurinol should be adjusted in patients with acute kidney injury.

TABLE 2 Therapeutic Options for Acute Gouty Inflammation

Drug Option	Level of Evidence	Typical Regimens
COX-nonselective NSAIDs	Grade A evidence for each regimen listed	Naproxen, 750-1000 mg PO daily in divided doses for 3 days; then 500-750 mg total daily for 4-7 days Sulindac, 300-400 mg/day in divided doses for 7-10 days Indomethacin, 150-200 mg PO daily in divided doses for 3 days; then 100 mg PO daily in divided doses for 4-7 days
COX-2–selective NSAIDs	Grade A	For example: celecoxib, 800 mg; then 400 mg on day 1 followed by 400 mg bid for 7 days
Systemic corticosteroids	Grade A evidence for oral prednisolone, 35 mg/day for five or six doses; lower evidence grades for other regimens	Prednisone, 30-60 mg/day for 3 days; then taper every 3 days by 10-15 mg less as a daily dose until discontinuation Oral prednisolone, 35 mg/day for 5-7 days Medrol dose pack (for less severe flares) or to initiate therapy In an NPO patient: • Triamcinolone, 60 mg IM once with additional corticosteroid treatment as needed • Methylprednisolone, 100-150 mg IV for 1-2 days
Intraarticular corticosteroids	Grade C evidence	Particularly useful for flares in a single large joint Triamcinolone acetonide preparations are especially useful Dose titrated to the size of the joint
ACTH	Grade C evidence	25 USP units of synthetic ACTH SC for less severe flares; 40 USP units IM or IV once for more severe flares (including larger joint flares and polyarticular gout) One or two repeated doses of synthetic ACTH at intervals of 12 hr are often required with each of these regimens
Oral colchicine	Grade A evidence for U.S. FDA-approved regimen	In the U.S.: To treat an early acute gout flare: 1.2 mg once followed by 0.6 mg in 1 hr and then 12 hr later; oral low-dose colchicine at prophylaxis doses until the acute gout flare resolves Outside the U.S.: 0.5 mg tid for several days is the EULAR-recommended dosing regimen Oral colchicine treatment of acute gout should be limited to once every 2 wk in those already taking a maintenance low dose of colchicine
Off-label use in U.S.: IL-1 antagonism	Grade C for anakinra; grade A for canakinumab	Use of anakinra (e.g., 100 mg SC daily for 3 days) or canakinumab (150 mg SC as single dose) for acute gout flare is not approved by the FDA, but canakinumab is approved by the EMA for this indication

ACTH, Adrenocorticotropic hormone; *bid,* twice a day; *COX,* cyclooxygenase; *EMA,* European Medicines Agency; *EULAR,* European League Against Rheumatism; *FDA,* U.S. Food and Drug Administration; *IL-1,* interleukin-1; *IM,* intramuscularly; *IV,* intravenously; *NPO,* nothing by mouth; *NSAID,* nonsteroidal antiinflammatory drug; *PO,* by mouth; *SC,* subcutaneously; *tid,* three times a day; *USP,* U.S. Pharmacopeia.

TABLE 3 Treatment of Gout

Acute Gout	Interval Gout	Treatment of Hyperuricemia
NSAIDs (preferred): Indomethacin 50 mg qid or ibuprofen 800 mg tid (or other NSAID in full doses). Contraindicated in patients with renal insufficiency and gastrointestinal disorders. *Or* **Colchicine, oral:** 1.2 mg followed by a second dose of 0.6 mg 1 hr later. Contraindicated in patients with renal insufficiency and gastrointestinal disorders *Or* **Intraarticular steroids** (Treatment of choice for large joint monoarthritis): Triamcinolone 40 mg or equivalent for knee *Or* Systemic steroid therapy (for patients in whom NSAIDs and colchicine are contraindicated) Prednisone 30-50 mg PO daily or in divided doses. May use lower dose in diabetic or postsurgical patients.	**Colchicine, oral:** 0.6-1.2 mg/day as prophylaxis against recurrent attacks. **NSAIDs may also be used for prophylaxis.** **Hypouricemic agent:** Indicated for patients with recurrent attacks despite prophylaxis, severe hyperuricemia, presence of tophi, urolithiasis, or gouty arthritis **Other:** Weight loss, reduce alcohol (especially beer), diet low in seafood, red meat, organ meat, and fructose	**Colchicine, oral:** 0.6-1.2 mg/day for 4-6 wk before initiating hypouricemic therapy and for several mo afterward to prevent recurrent attacks during initiation of hypouricemic therapy. *And* **Allopurinol:** Initial dose 100 mg/day in patients with renal insufficiency or very high uric acid levels. Increase dose as needed to attain uric acid less than 6 mg/dl. *Or* **Uricosuric agent** (Use only in patients with good renal function and <600 mg uric acid in a 24-hr collection): probenecid, 0.5-1 g bid, or sulfinpyrazone 100 mg tid or qid. **Other:** Consider febuxostat for patients allergic to allopurinol and the addition of lesinurad in patients resistant to xanthine oxidase inhibitors. Pegloticase may be useful for selected patients with severe tophaceous gout.

NSAID, nonsteroidal antiinflammatory drug; *PO,* by mouth; *qid,* four times a day; *tid,* three times a day.

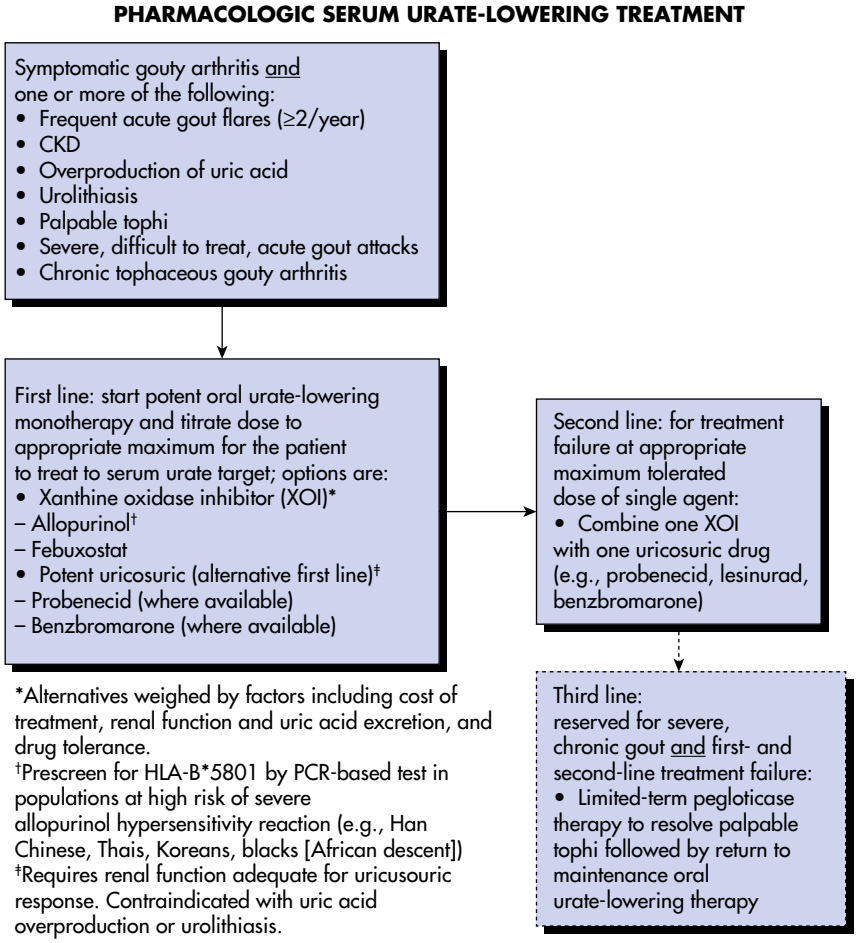

FIG. 6 Algorithm for pharmacologic serum urate–lowering treatment of hyperuricemia in patients with a confirmed diagnosis of gout. The algorithm, discussed in the text, summarizes the first-, second-, and third-line approaches to pharmacologic urate-lowering therapy, including management of refractory hyperuricemia in difficult gout. *CKD*, Chronic kidney disease; *PCR*, polymerase chain reaction. FIG. E4 Chronic tophaceous gout. Asymmetric large eccentric soft tissue lumps (tophi). Underlying gouty erosions are seen at several sites, particularly the distal interphalangeal joint of the right little finger and the carpometacarpal joint of the thumb. (From Adam A et al: *Grainger & Allison's diagnostic radiology,* ed 5, London, 2007, Churchill Livingstone; in Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, Philadelphia 2019, Elsevier.)

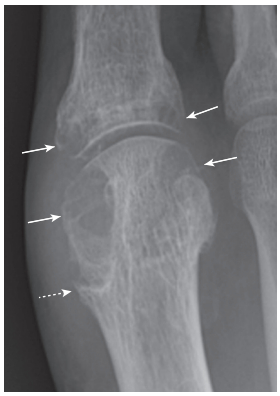

FIG. E5 Classic radiographic findings of gout in a 69-year-old man. Note the asymmetric, well-marginated erosions in the head of the first metatarsal and lesser erosions in the opposing phalanx *(solid arrows).* The medial erosions are characteristically larger than the lateral erosions. There is a "hook" sign on the inferior margin of the large medial erosion of the head of the metatarsal *(dashed arrow).* The joint space is preserved, and there is no osteopenia. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, WB Saunders.)

Graft-versus-Host Disease

BASIC INFORMATION

DEFINITION

Graft-versus-host disease (GVHD) is a complication of allogeneic hematopoietic stem cell transplantation (HSCT) in which a patient's bone marrow is replaced by a donor's, and the donor cells recognize the patient's organs as foreign and launch an immunologic attack on them. GVHD is reported rarely after autologous bone marrow transplant and blood transfusion. GVHD that occurs between the time of engraftment and up to 100 days afterward is termed *acute GVHD.* GVHD that occurs beyond 100 days is termed *chronic GVHD*.

SYNONYM

GVHD

ICD-10CM CODE

D89.813 Graft-versus-host disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence of acute GVHD is 25% to 35% in recipients of fully matched sibling donor grafts and 40% to 50% in recipients of matched unrelated donor grafts. The incidence of chronic GVHD is 30% in recipients of fully histocompatible transplants and 60% to 70% in mismatched or unrelated donor recipients.

PREDOMINANT AGE AND SEX: Older age and female donor-to-male recipient transplant are risk factors for GVHD.

GENETICS: Degree of HLA mismatch is a risk factor for GVHD.

RISK FACTORS:

- Degree of HLA mismatches is the strongest risk factor
- Source of graft (peripheral blood or bone marrow greater than umbilical cord blood)
- Female donor-to-male recipient
- Multiparous donors
- Intensity of the transplant conditioning regimen
- Acute GVHD prophylactic regimen
- Transplants that achieve full donor chimerism
- CMV mismatch
- Older patients, those with poor functional status

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute GVHD: Median onset is 21 to 25 days post-HSCT.
- Skin is affected in approximately 80% of patients, gastrointestinal (GI) tract in 50%, and liver in 50%.
- Chronic GVHD primarily occurs within the first yr after HSCT, but 5% to 10% of patients develop HSCT after 1 yr. About 30% of chronic GVHD is de novo without history of acute GVHD. The median time to diagnosis of chronic GVHD is 4.5 mo. Common clinical manifestations of chronic GVHD are summarized in Table E1.
- Skin lesions include maculopapular rash commonly involving the neck, shoulders, palms, and soles.
- More severe lesions include blisters, ulcers, and bullae.
- GI manifestations include anorexia, nausea, vomiting, abdominal pain, ileus, secretory diarrhea that is often copious, and hematochezia. The diarrheal volume determines the severity of disease.
- Liver involvement occurs as a result of damage to biliary canaliculi, causing cholestasis with hyperbilirubinemia and elevated alkaline phosphatase. Severity of liver disease is evaluated based on serum bilirubin levels.

ETIOLOGY

GVHD occurs when immune cells transplanted from a donor (the graft) recognize the transplant recipient (the host) as foreign, and initiate an immune attack against the recipient organs. The pathophysiology of GVHD is illustrated in Fig. E1.

TABLE E1 Common Clinical Manifestations of Chronic Graft-versus-Host Disease

Organ System	Clinical Manifestations
Cutaneous	Poikiloderma, lichen planus, dermal sclerosis, morphea-like features, hypopigmentation or hyperpigmentation, ichthyosis, nail dystrophy, onycholysis
Ocular	Keratoconjunctivitis sicca, conjunctivitis, corneal ulcerations
Oral	Lichen planus, hyperkeratotic plaques, xerostomia, mucosal atrophy, ulcers, restriction of mouth opening from sclerosis
Pulmonary	Bronchiolitis obliterans, bronchiolitis obliterans–organizing pneumonia
Gastrointestinal	Esophageal web and strictures, malabsorption syndrome, exocrine pancreatic insufficiency
Hepatic	Cholestasis
Genitourinary	Vaginal stenosis or scarring, lichen planus
Musculoskeletal	Fasciitis, joint contractures from sclerosis, myositis or polymyositis, arthritis
Hematopoietic	Thrombocytopenia, eosinophilia, lymphopenia, hemolytic anemia, hypogammaglobulinemia

From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

DIAGNOSIS

The National Institutes of Health (NIH) consensus criteria used to diagnose GVHD classify manifestations of GVHD as "diagnostic" or "distinctive" of chronic GVHD, or as common to both acute and chronic GVHD.

Common diagnostic criteria sufficient to establish a diagnosis of chronic GVHD:

- Poikiloderma
- Lichen planus–like features
- Esophageal web
- Strictures or stenosis in the upper to middle third of the esophagus
- Bronchiolitis obliterans diagnosed with lung biopsy

Common distinctive criteria that are encountered in chronic GVHD but are insufficient by themselves to establish a diagnosis include the following:

- Depigmentation
- Cicatricial conjunctivitis
- Keratoconjunctivitis sicca
- Bronchiolitis obliterans diagnosed with pulmonary function tests (PFTs) and radiology
- Myositis or polymyositis

To make a diagnosis of chronic GVHD, at least one diagnostic clinical sign of chronic GVHD must be present or at least one distinctive manifestation must be confirmed by pertinent biopsy or other relevant tests in the same or another organ. The clinical features, staging, and grading of acute GVHD are summarized in Table E2.

DIFFERENTIAL DIAGNOSIS

- Engraftment syndrome
- Erythema multiforme
- Malignancy
- Hepatic sinusoidal obstructive syndrome
- Drug eruptions and toxicities
- Dermatomyositis
- Systemic sclerosis

WORKUP

Although the diagnosis of GVHD is mostly made based on clinical signs and symptoms, biomarkers and organ-specific histology may help establish diagnosis.

LABORATORY TESTS

A panel of plasma biomarkers, including IL-2-receptor-α, TNF receptor-1, IL-8, and hepatocyte growth factor, has been suggested as a confirmatory tool for the diagnosis of GVHD at the onset of clinical manifestations. However, biomarker identification remains an active area of investigation.

IMAGING STUDIES

Positron emission tomography (PET) scanning may be used to distinguish intestinal GVHD from other diagnoses in patients with intestinal GVHD.

TREATMENT

Treatment of GVHD:

- Treatment depends on the organs involved and the severity of GVHD. Commonly administered drugs for GVHD are summarized in Table E3.

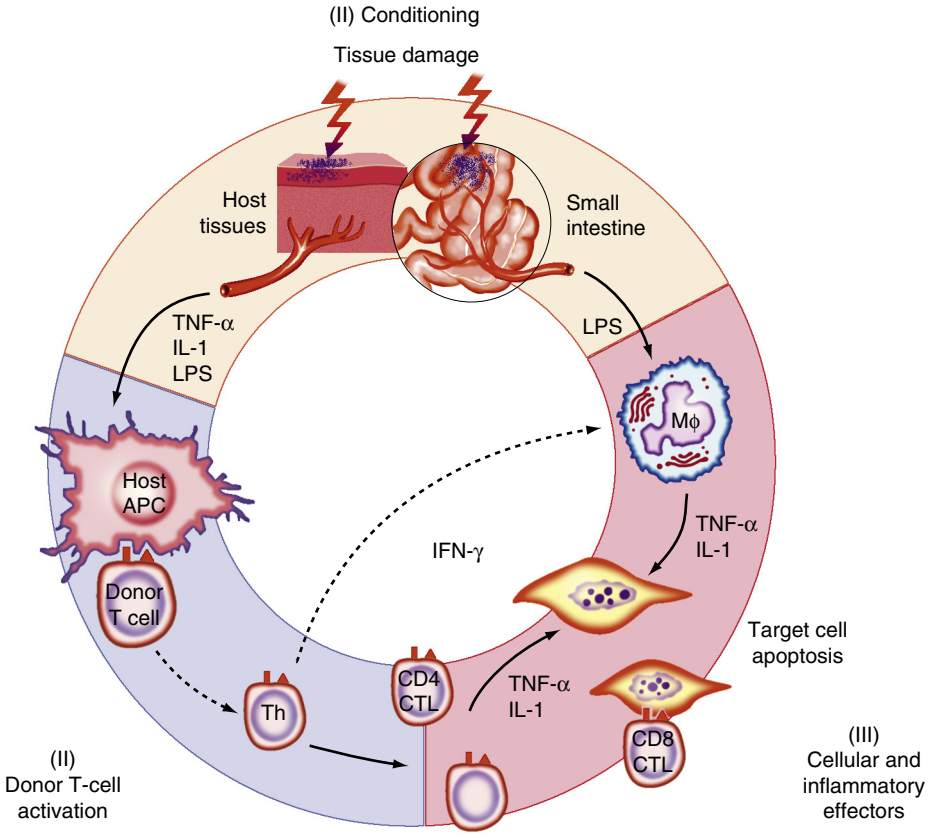

FIG. E1 Pathophysiology of graft-versus-host-disease (GVHD). During step 1, both irradiation and chemotherapy damage and activate host tissues, including intestinal mucosa, liver, and the skin. Activated host cells subsequently secrete inflammatory cytokines (e.g., TNF-α and IL-1) that can be measured in the systemic circulation. The cytokine release has important effects on host antigen-presenting cells (APCs), including increased expression of intercellular and vascular cell adhesion molecules and MHC class II antigens. These changes in the APCs enhance the recognition of host MHC and/or minor H antigens by mature donor T cells. During step 2, donor T-cell activation is characterized by proliferation of GVHD T cells and secretion of the Th1 cytokines IL-2 and IFN-γ. Both of these cytokines play central roles in clonal T-cell expansion, induction of CTL and NK cell responses, and priming of mononuclear phagocytes. In step 3, mononuclear phagocytes primed by IFN-γ are triggered by a second signal such as endotoxin LPS to secrete cytopathic amounts of IL-I and TNF-α. LPS can leak through the intestinal mucosa damaged by the conditioning regimen to stimulate gut-associated lymphoid tissue or Kupffer cells in the liver; LPS that penetrates the epidermis may stimulate keratinocytes, dermal fibroblasts, and macrophages to produce similar cytokines in the skin. This mechanism results in the amplification of local tissue injury and further production of inflammatory effectors such as nitric oxide, which, together with CTL and NK effectors, leads to the observed target tissue destruction in the stem cell transplant host. CTL effectors use Fas/FasL, perforin/granzyme B, and membrane-bound cytokines to lyse target cells. *APC,* Antigen-presenting cell; *CTL,* cytotoxic T lymphocyte; *ICAM,* intercellular adhesion molecule; *IFN,* interferon; *IL,* interleukin; *LPS,* lipopolysaccharide; *MHC,* major histocompatibility complex; *NK,* natural killer; *TNF,* tumor necrosis factor. (From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

TABLE E2 Clinical Manifestations and Staging of Acute Graft-versus-Host Disease

Organ	Clinical Manifestations	Staging
Skin	Erythematous, maculopapular rash involving palms and soles; may become confluent Severe disease: Bullae	Stage 1: <25% rash Stage 2: 25%-50% rash Stage 3: Generalized erythroderma Stage 4: Bullae
Liver	Painless jaundice with conjugated hyperbilirubinemia and increased alkaline phosphatase	Stage 1: Total bilirubin 2-3 mg/dl Stage 2: Total bilirubin 3.1-6 mg/dl Stage 3: Total bilirubin 6.1-15 mg/dl Stage 4: Total bilirubin >15 mg/dl
Gastrointestinal tract	Upper: Nausea, vomiting, anorexia Lower: Diarrhea, abdominal cramps, distension, ileus, bleeding	Stage 1: Diarrhea >500 ml/day Stage 2: Diarrhea >1000 ml/day Stage 3: Diarrhea >1500 ml/day Stage 4: Ileus, bleeding

From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

- In mild cutaneous GVHD, topical steroids may be used along with optimization of prophylactic regimen.
- Systemic methyl prednisone 2 mg/kg per day in divided doses should be used for grade 2 or higher GVHD, in addition to the optimization of prophylactic measures. Corticosteroid treatment can be tapered over several mo.
- In GVHD with gastrointestinal involvement, systemic glucocorticoids plus oral nonabsorbable steroids should be used. In addition, octreotide may reduce diarrhea.
- Patients who demonstrate progression of disease by day 5 of therapy or no response by day 7 are considered to have glucocorticoid resistance. There is no standard therapy for steroid refractory GVHD. Second-line agents in treatment of GVHD include mycophenolate mofetil, etanercept, pentostatin,

TABLE E3 Commonly Administered Drugs for Graft-versus-Host Disease Prophylaxis and Treatment

Drug	Mechanism	Adverse Effects
Corticosteroids	Direct lymphocyte toxicity; suppress proinflammatory cytokines such as TNF-α	Hyperglycemia, acute psychosis, severe myopathy, neuropathy, osteoporosis, cataract development
Methotrexate (MTX)	Antimetabolite: inhibits T-cell proliferation	Significant renal, hepatic, and gastrointestinal toxicities
Cyclosporine A (CSA)	IL-2 suppressor; blocks Ca^{2+}-dependent signal transduction distal to TCR engagement	Renal and hepatic insufficiency, hypertension, hyperglycemia, headache, nausea and vomiting, hirsutism, gum hypertrophy, seizure with severe toxicity
Tacrolimus (FK506)	IL-2 receptor; blocks Ca^{2+}-dependent signal transduction distal to TCR engagement	Similar to cyclosporine A
Mycophenolate mofetil (MMF)	Inhibits de novo purine synthesis	Body aches, abdominal pain, nausea and vomiting, diarrhea, neutropenia
Sirolimus	mTOR inhibitor	Thrombocytopenia, hyperlipidemia, TTP
Antithymocyte globulin (ATG)	Polyclonal immunoglobulin	Anaphylaxis, serum sickness

Ca^{2+}, Calcium ion; *IL-2,* interleukin-2; *mTOR,* mammalian target of rapamycin; *TCR,* T-cell receptor; *TNF-α,* tumor necrosis factor-α; *TTP,* thrombotic thrombocytopenic purpura.
From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E4 Glucksberg Criteria for Staging of Acute Graft-versus-Host Disease[a]

Overall Grade	Skin	Liver		Gut
I	1-2	0		0
II	1-3	1	*and/or*	1
III	2-3	2-4	*and/or*	2-3
IV	2-4	2-4	*and/or*	2-4

[a]See Table E2 for individual organ staging. Traditionally, individual organs are staged without regard to attribution. The overall grade of graft-versus-host disease, however, reflects the actual extent of graft-versus-host disease. To achieve each overall grade, skin disease, liver, and/or gut involvement are required.
From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

alpha-1 antitrypsin, sirolimus, ruxolitinib antithymocyte globulin, and extracorporeal photopheresis.

ACUTE GENERAL Rx

Acute treatment involves topical or systemic corticosteroids. Second-line agents can be used in steroid-resistant cases.

CHRONIC Rx

Corticosteroids, tapered over several mo, can be used in chronic treatment of GVHD.

DISPOSITION

Patients should be directed to individuals who originally initiated organ or bone marrow transplantation surgery.

REFERRAL

Physicians with expertise in immunosuppression

PEARLS & CONSIDERATIONS

COMMENTS

GVHD is a potentially fatal disorder that occurs after an allogeneic transplant of bone marrow, peripheral blood stem cells, or solid organs. The donor bone marrow or peripheral blood stem cells attack the recipient's organs. Immunosuppression is required to prevent and treat this disorder.

GRADING OF GVHD: Severity is defined by the International Blood and Marrow Transplant Research (IBMTR) grading system:

- Grade A: stage 1 skin involvement alone (maculopapular rash over <25% of the body) with no liver or gastrointestinal involvement
- Grade B: stage 2 skin involvement; stage 1 to 2 gut or liver involvement
- Grade C: stage 3 involvement of any organ system (generalized erythroderma; bilirubin 6.1 to 15.0 mg/dl; diarrhea 1500 to 2000 ml/day)
- Grade D: stage 4 involvement of any organ system (generalized erythroderma with bullous formation; bilirubin >15 mg/dl; diarrhea >2000 ml/day or pain or ileus)

Glucksberg criteria for staging of acute GVHD are summarized in Table E4.

PREVENTION

- Prophylactic regimen should be decided based on underlying disease, the degree of HLA disparity, the conditioning regimen, and patient characteristics.
- Mycophenolate and calcineurin inhibitors should be used in patients undergoing reduced intensity allogeneic HSCT.
- For patients who receive myeloablative or reduced intensity conditioning, antithymocyte globulin can be added to the prophylactic regimen.

BASIC INFORMATION

DEFINITION

Granuloma annulare (GA) is a chronic, usually self-limited, inflammatory disorder of the dermis that classically presents as arciform to annular plaques located on the extremities.

SYNONYMS

Pseudorheumatoid nodule—subcutaneous granuloma annulare
GA

ICD-10CM CODE
L92.0 Granuloma annulare

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common in children and young adults; most cases of localized GA are diagnosed in patients <30 yr
- Female predominance (2:1)
- Disseminated form associated with diabetes mellitus
- Recurrent in 40% of affected individuals
- A generalized form of GA can occur in up to 15% of patients

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The main clinical variants of GA are localized (75%), disseminated (>10 lesions), subcutaneous (occurring primarily in children aged 2 to 5 yr), patch-type or macular GA, and perforating (rare form manifesting with 1- to 4-mm papules with a central crust usually appearing on the dorsal hands).
- Localized GA starts as a small ring of colored skin or pale erythematous papules. More common in children and young to middle-age adults. Usually, only one or a few lesions occur at any one time.
- Lesions coalesce and evolve into annular plaques over several wk.
- Plaques undergo central involution and increase in diameter over several mo (0.5 to 5 cm).
- Most frequently found on the lateral and dorsal surfaces of the hands and feet (Fig. E1 and Fig. E2).
- Most lesions resolve spontaneously after several mo.
- The generalized form of GA is characterized by hundreds of small (lesions rarely exceed 5 cm in diameter), flesh-colored papules in a symmetric distribution on the trunk and extremities. It most commonly affects women in the fifth or sixth decades but can also be seen in adolescents and children. Some patients are completely asymptomatic, whereas others complain of severe pruritus.
- Macular GA is more common in women between ages 30 to 70 and manifests with flat or slightly palpable erythematous or red-brown lesions on upper medial thighs and in bathing-trunk distribution.
- Deep dermal GA (subcutaneous GA) presents as large, painless, skin-colored nodules that are frequently mistaken for rheumatoid nodules.

ETIOLOGY

Unknown, but may be related to vasculitis, trauma, monocyte activation, or delayed hypersensitivity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Tinea corporis
- Lichen planus
- Necrobiosis lipoidica diabeticorum
- Sarcoidosis
- Rheumatoid nodules
- Late secondary or tertiary syphilis
- Arcuate and annular plaques of mycosis fungoides
- Papular GA can simulate insect bites, secondary syphilis, xanthoma
- Annular elastolytic giant cell granuloma

WORKUP

- Diagnosis based on clinical appearance and presentation
- Biopsy when diagnosis is unclear

LABORATORY TESTS

- No laboratory tests will help confirm the diagnosis.
- Biopsy shows focal degeneration of collagen and elastic fibers, mucin deposition, and perivascular and interstitial lymphohistiocytic infiltrate in the upper and middle dermis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Reassurance, given the self-limited and benign nature of GA

CHRONIC Rx

High-potency topical corticosteroids with or without occlusion and intralesional steroid injection into elevated border with triamcinolone 2.5 to 10 mg/ml are useful first-line local therapies.

- Cryosurgery, psoralen ultraviolet-A (UVA) range or UVA-1 therapy, and carbon dioxide laser treatment can also be used.
- Systemic agents (e.g., niacinamide, hydroxychloroquine, chloroquine, cyclosporine, dapsone) are generally reserved for severe cases. Recent case reports indicate positive outcomes with tacrolimus and pimecrolimus and the tumor necrosis factor infliximab.

DISPOSITION

Most lesions resolve spontaneously within 2 yr.

REFERRAL

Dermatology referral recommended for symptomatic, disseminated disease

PEARLS & CONSIDERATIONS

COMMENTS

GA has been described as a paraneoplastic granulomatous reaction to Hodgkin disease, non-Hodgkin lymphoma, solid organ tumors, and mycosis fungoides.

Granuloma Annulare (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

FIG. E1 Granuloma annulare. Annular, flesh-colored, nonscaly plaques. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Edinburgh, 2016, Elsevier.)

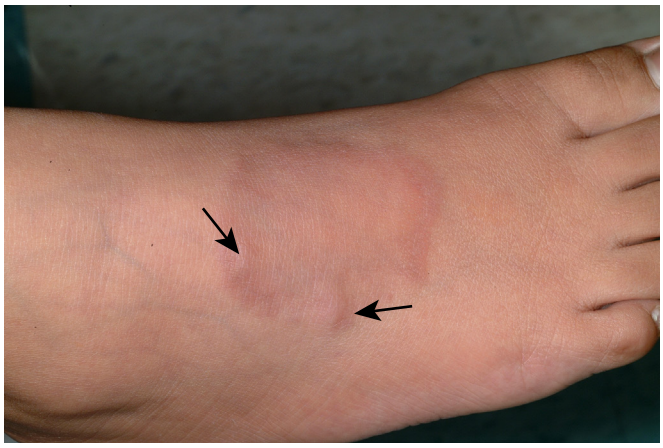

FIG. E2 Granuloma annulare. This patient's plaque reveals both cutaneous and subcutaneous (*arrows*) involvement. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Edinburgh, 2016, Elsevier.)

BASIC INFORMATION

DEFINITION

Granuloma inguinale is a genital ulcerative disease caused by a gram-negative bacterium, *Klebsiella granulomatis,* which may be sexually transmitted. It can also be spread through close, long-term, nonsexual contact.

SYNONYMS

Donovanosis
Calymmatobacterium granulomatis

ICD-10CM CODE
A58 Granuloma inguinale

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Rare in the U.S. (<100 cases reported annually) and other developed countries
PREVALENCE: Endemic in some tropical and developing areas, including India, Papua New Guinea, the Caribbean, Central Australia, and southern Africa; incubation period is variable (1 to 2 wk)
PREDOMINANT SEX: Can affect both males and females

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinically, the disease is commonly characterized as painless, slowly progressive ulcerative lesions on the genitals or perineum without regional lymphadenopathy; subcutaneous granulomas (pseudobuboes) might also occur. The lesions are highly vascular (i.e., beefy red appearance [Fig. E1]) and bleed easily on contact.
- Extragenital infection can occur with extension of infection to the pelvis, or it can disseminate to bones, intraabdominal organs, or the mouth.
- Pathogenic features:
  1. Large, infected mononuclear cell containing many Donovan bodies
  2. Intracytoplasmic location

ETIOLOGY

K. granulomatis is a gram-negative bacillus that reproduces within polymorphonuclear cells, plasma cells, and histiocytes, causing the infected cells to rupture, releasing 20 to 30 organisms.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Carcinoma
- Secondary syphilis: Condylomata lata
- Amebiasis: Necrotic ulceration
- Concurrent infections
- Lymphogranuloma venereum
- Chancroid
- Genital herpes

WORKUP

- Check for clinical manifestations.
  1. Lesions bleed easily.
  2. Lesions are sharply defined and painless.
  3. Secondary infection may ensue.
  4. Inguinal involvement may cause pseudobuboes.
  5. Elephantiasis can result from obstruction of lymphatics.
  6. Suppuration and sinus formation are rare in female patients.
- Screen for other sexually transmitted diseases.
- Exclude other causes of lesions.
- Obtain stained, crushed prep from lesion.

LABORATORY TESTS

- The causative organism is difficult to culture and diagnosis requires visualization of dark-staining Donovan bodies with Wright stain (observation of Donovan bodies [intracellular bacteria]; organisms in vacuoles within macrophages) via biopsy of the ulcer or tissue crush prep. No FDA-cleared molecular tests for the detection of *K. granulomatis* DNA exist.
- HIV testing of all patients.

TREATMENT

ACUTE GENERAL Rx

Recommended regimen:
- Azithromycin 1 g PO once per wk or 500 mg daily for at least 3 wk and until all lesions have completely healed

Alternative regimens:
- Doxycycline 100 mg PO bid for at least 3 wk and until all lesions have completely healed
- Ciprofloxacin 750 mg PO bid for at least 3 wk and until all lesions have completely healed
- Erythromycin base 500 mg PO qid for at least 3 wk and until all lesions have completely healed
- Trimethoprim/sulfamethoxazole, one double-strength tablet (160 mg/800 mg) PO bid for at least 3 wk and until all lesions have completely healed
- Add gentamicin 1 mg/kg IV q8h if no improvement within the first few days of therapy

CHRONIC Rx

If there is a poor initial response, extend treatment. Treatment of relapses is often necessary. Patients should be counseled to avoid risky sex practices and to abstain from intercourse until infection is cleared.

DISPOSITION

Follow up clinically until signs and symptoms have resolved, then routine annual or semiannual visits.

REFERRAL

If response is poor, consider referral to an infectious disease specialist.

PEARLS & CONSIDERATIONS

COMMENTS

- Sexual partners within 60 days before onset of patient's symptoms should be examined and offered therapy.
- Pregnant women should be treated with erythromycin regimen.
- Patient education material can be obtained from local and state health clinics and also from American College of Obstetricians and Gynecologists.

BASIC INFORMATION

DEFINITION

Granulomatosis with polyangiitis (GPA), formerly known as "Wegener granulomatosis," is a multisystem necrotizing vasculitis that generally affects the upper and lower respiratory tracts and the kidneys. It is characterized as an ANCA-associated granulomatous small-vessel vasculitis. Clinical manifestations depend on the tropism of blood vessel involvement and organ systems commonly affected beyond the respiratory tract and kidneys and can include neurologic and skin involvement, and the musculoskeletal systems as well as the gastrointestinal tract.

The disease can also present in a limited form that is generally confined to the upper respiratory tract and can be managed less aggressively than the more diffuse systemic form.

SYNONYMS

GPA
Wegener granulomatosis (WG)

ICD-10CM CODE
M31.3 Wegener granulomatosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 3/100,000 in recent U.S. epidemiologic studies, equal in men and women, more common in whites
MEAN AGE AT ONSET: 41 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical manifestations often vary with the stage of the disease and degree of organ involvement; localized disease often has upper respiratory tract involvement without systemic vasculitis, whereas systemic disease stages include early systemic, generalized, and severe disease.
- Frequent manifestations are:
  1. Upper respiratory tract: Chronic sinusitis, chronic otitis media, mastoiditis, nasal crusting, obstruction and epistaxis, nasal septal perforation, nasal lacrimal duct stenosis, saddle nose deformities (Fig. E1), and tracheal and subglottic stenosis. Up to 90% of patients with GPA have one or more nasal manifestations.
  2. Eyes: Conjunctivitis, ulcerative keratosis, episcleritis or scleritis, optic neuropathy, nasolacrimal duct obstruction, retinal vasculitis, uveitis, proptosis.
  3. Ears: Sensorineural and conductive hearing loss, otorrhea, and polychondritis.
  4. Mouth: Chronic ulcerative lesions of the oral mucosa, "mulberry" gingivitis.
  5. Lung: Nodules, pulmonary infiltrates or effusions, cavitary lesions, and frank hemoptysis (6% to 85%).
  6. Kidney: Rapidly progressive glomerulonephritis (38% to 70%), microscopic hematuria with or without red cell casts, and proteinuria.
  7. Skin: Cutaneous nodules over extensor surfaces of joints, necrotizing skin lesions (Fig. E2), palpable purpura (30% to 46%), urticaria, and livedo reticularis.
  8. Nervous system: Mononeuritis multiplex and peripheral neuropathies (15% to 40%), meningeal inflammation (pachymeningitis), headaches, and CNS involvement (7% to 11%).
  9. Musculoskeletal: Monoarthritis or polyarthritis (nondeforming), usually affecting large joints (60%).
  10. Constitutional: Fever (23% to 30%), weight loss (50%), and fatigue (61%).

ETIOLOGY

Unknown; complex immune-mediated disorder, believed to begin with granulomatous inflammation that progresses to systemic vasculitis. Various risk factors, including genetic, infectious and environmental triggers, have been considered.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other granulomatous lung diseases (e.g., sarcoidosis, lymphomatoid granulomatosis, eosinophilic granulomatosis with polyangiitis [EGPA, formerly Churg-Strauss syndrome]), necrotizing bronchocentric granulomatosis). The differential diagnosis of granulomatous lung disease is described in Section II. Table E1 describes differential diagnostic features of ANCA-associated vasculitis.
- Other ANCA-associated vasculitides, including microscopic polyangiitis (MPA).
- Goodpasture disease, other causes of glomerulonephritis (e.g., poststreptococcal nephritis).
- Neoplasms (especially lymphoproliferative disease).

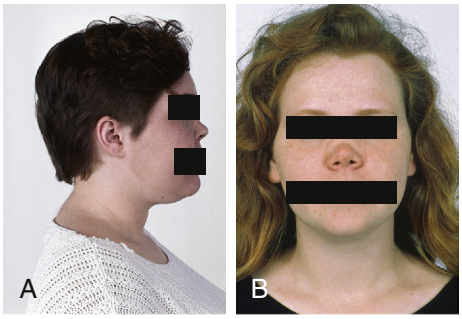

FIG. E1 Saddle-nose deformity in a patient with Wegener granulomatosis. (From *Kelley's textbook of rheumatology*, ed 8, Philadelphia, 2009, Elsevier.)

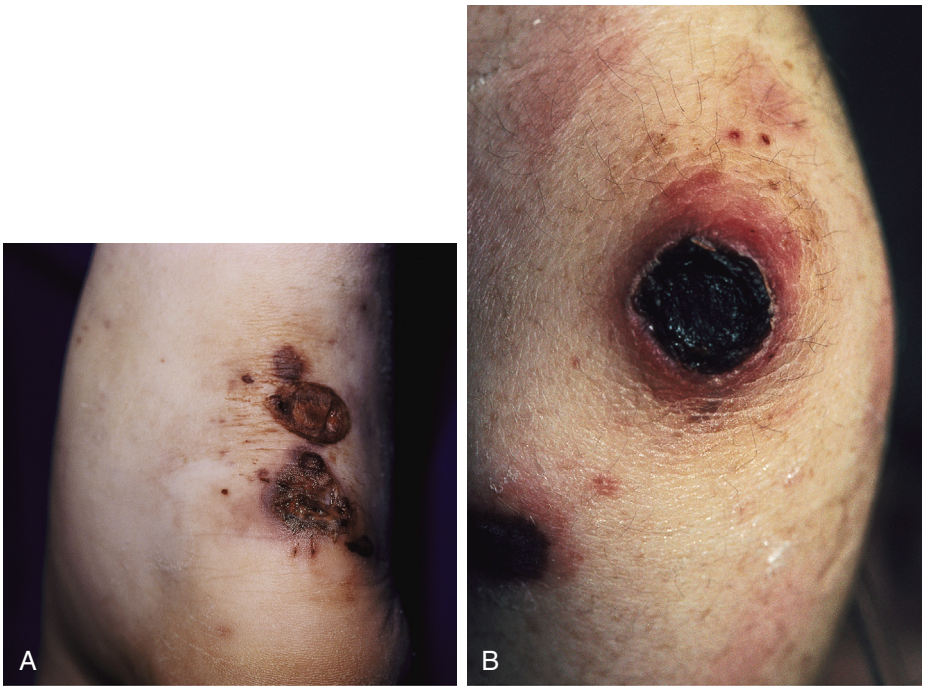

FIG. E2 Granulomatosis with polyangiitis (GPA; formerly known as Wegener granulomatosis). Painful, ulcerative, necrotic plaques on the ankle **(A)** and elbow **(B)** of a female with GPA. (From Paller AS, *Mancini AJ: Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Edinburgh, 2016, Elsevier.)

- Bacterial or fungal sinusitis.
- Viral infections.
- Cocaine-induced midline destructive lesions and levamisole-induced vasculitis.

WORKUP

- Granulomatosis with polyangiitis should be suspected in a patient presenting with sinus disease that is unresponsive to conventional treatment and/or pulmonary hemorrhage, glomerulonephritis, mononeuritis multiplex resulting in wrist drop or foot drop or progressive migratory arthralgias or arthritis.
- Chest x-ray, laboratory evaluation, PFTs, and tissue biopsy for granulomatous lesions (Fig. E3).

TABLE E1 Differential Diagnostic Features of the Antineutrophil Cytoplasm Antibody–Associated Vasculitides

Feature	Microscopic Polyangiitis (MPA)	GPA (Wegener Granulomatosis)	EGPA (Churg-Strauss Syndrome)	Comments
Glomerulonephritis	+++	+++	+	Progressive renal failure uncommon in EGPA
Pulmonary infiltrates or nodules	++	+++	+++	Asthma and eosinophilia in EGPA
Alveolar hemorrhage	++	++	+	
Upper airway disease	+	+++	++	Ear, nose, and throat disease usually favors GPA
Skin, purpura	+++	+	++	
Peripheral nerve involvement	+	++	+++	Often a prominent feature of EGPA
Central nervous system involvement	+	+	+	

+++, Very commonly seen; ++, seen often; +, uncommon finding; *EGPA*, eosinophilic granulomatosis with polyangiitis; *GPA*, granulomatosis with polyangiitis.
From Firestein GS et al: *Kelly's textbook of rheumatology*, ed 9, Philadelphia, 2013, WB Saunders.

LABORATORY TESTS

- ANCA serology: Most patients with GPA have a positive test result for cytoplasmic pattern of ANCA (c-ANCA). In GPA, ANCAs are predominantly directed against proteinase 3 (anti-PR3), which is the confirmatory test in a patient with positive ANCA staining on immunofluorescence. However, between 10% and 15% of patients with GPA are positive for p-ANCA (usually MPO), and up to 10% are ANCA negative.
- CBC: Anemia, leukocytosis, thrombocytosis (>400,000/μL).
- Chemistry: Elevated serum creatinine, decreased creatinine clearance.
- Urinalysis: May reveal hematuria, RBC casts, and proteinuria.
- Inflammatory markers: Increased ESR, positive rheumatoid factor, and elevated C-reactive protein may be found.
- Liver function, hepatitis serologies, cryoglobulins, HIV screens, ANA, C3, C4, anti-GBM, and cultures to exclude other processes with similar constitutional symptoms.

IMAGING STUDIES

- Chest x-ray: May reveal bilateral multiple nodules, cavitary mass lesions, pleural effusion (20%). Up to one third of patients without pulmonary signs or symptoms have an abnormal chest x-ray (Fig. E4).
- Computed tomography of sinuses, (Fig. E5), computed tomography of chest, MRI of brain (Fig. E6) depending on symptoms

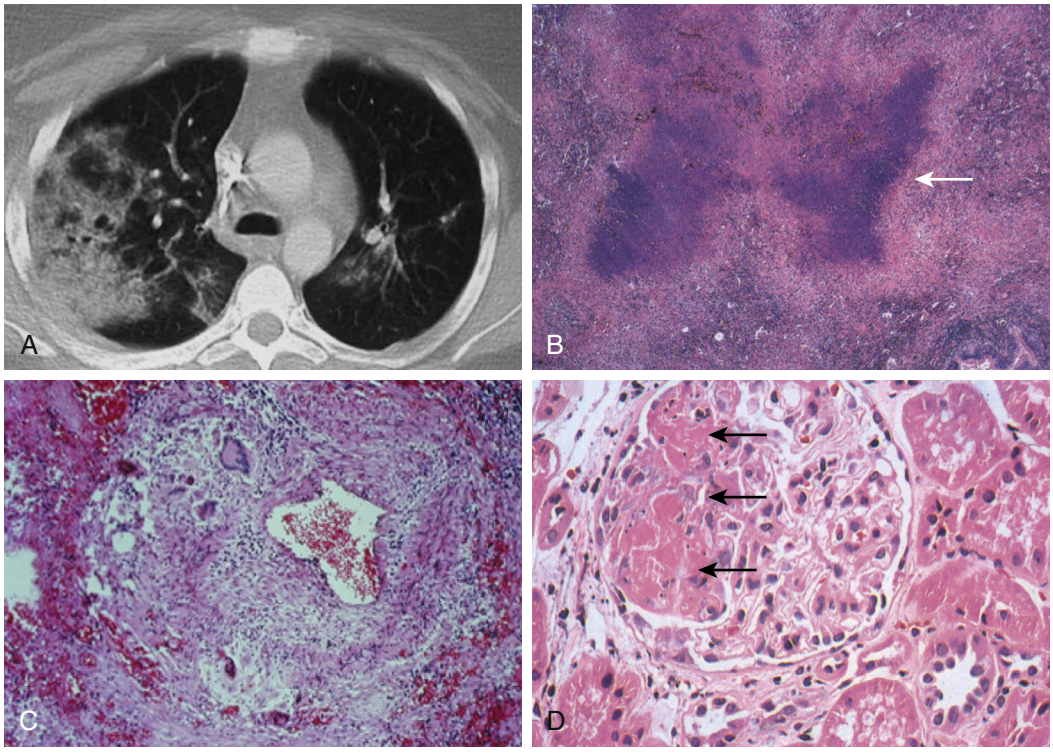

FIG. E3 **A,** Chest computed tomographic scan of a patient with granulomatosis with polyangiitis (GPA) shows typical nodular lung infiltrate with cavitation. **B,** Low-power view of granulomatous inflammation and geographic necrosis (*arrow*) in a lung biopsy from a patient with GPA. **C,** Granulomatous vasculitis involving a small pulmonary artery in the lung of a patient with GPA. The vessel wall is markedly thickened with an inflammatory infiltrate that includes multinucleated giant cells. **D,** Glomeruli showing segmental necrosis with early crescent formation (*arrows*). (From Adkinson NF et al: *Middleton's allergy principles and practice*, ed 8, Philadelphia, 2014, WB Saunders.)

FIG. E4 Chest radiograph shows multiple cavitary pulmonary nodules in patient with Wegener granulomatosis. (From Weinberg SE et al: *Principles of pulmonary medicine,* ed 5, Philadelphia, 2008, WB Saunders.)

- PFTs: Useful in detecting stenosis of the airways.
- Fiber optic bronchoscopy with BAL and endoscopic ENT examination: Nasal crusting ("golden crusts") are typical on evaluation (Fig. E7).
- Biopsy of one or more affected organs should be attempted; the most reliable source for tissue diagnosis is the lung. Lesions in the nasopharynx can be easily biopsied, but biopsy yield is only 20%. Biopsy of radiographically abnormal pulmonary parenchyma provides the highest yield (>90%).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Ensure proper airway drainage.
- Give nutritional counseling.

ACUTE GENERAL Rx

- Immunosuppressive therapy should be considered in all patients with GPA.
- Induction therapy in GPA consists of glucocorticoid with either cyclophosphamide or rituximab. Selected patients with severe disease may benefit from the addition of plasma exchange to this regimen.
- Historically, the gold standard for treatment is pulse methylprednisolone followed by prednisone 60 to 80 mg/day and pulse cyclophosphamide (1 g/m^2 every 4 wk) or daily oral cyclophosphamide (2 mg/kg/day). This was generally effective and used to control clinical manifestations. MESNA can be used with cyclophosphamide for the prevention of cyclophosphamide-induced hemorrhagic cystitis.
- Based on the RAVE trial, rituximab (375 mg/m^2/wk ×4 wk) appears to be more effective than traditional therapy in treating GPA that presents with disease flares and is at least as effective as traditional therapy for the induction of remission. The RITUXVAS trial concluded that a combined cyclophosphamide-rituximab regimen was not inferior to pulse cyclophosphamide alone. Both of these studies used concurrent methylprednisolone followed by prednisone.
- Methotrexate and glucocorticoids alone may be used with mild extrarenal disease or little to no renal involvement, or with limited sinus and upper airway involvement.
- For severe active renal disease, the MEPEX trial demonstrated that plasma exchange in addition to cyclophosphamide and glucocorticoids may enhance renal function recovery.
- Potentially useful agents for maintenance therapy include rituximab, methotrexate, azathioprine, and mycophenolate mofetil. The MAINRITSAN trial showed that rituximab may be preferable for maintenance therapy, and the CYCAZAREM (for azathioprine) and LEM (for leflunomide) trials showed that these agents can also be used. The WEGENT study showed oral methotrexate and azathioprine were noninferior for maintenance than intravenous cyclophosphamide.

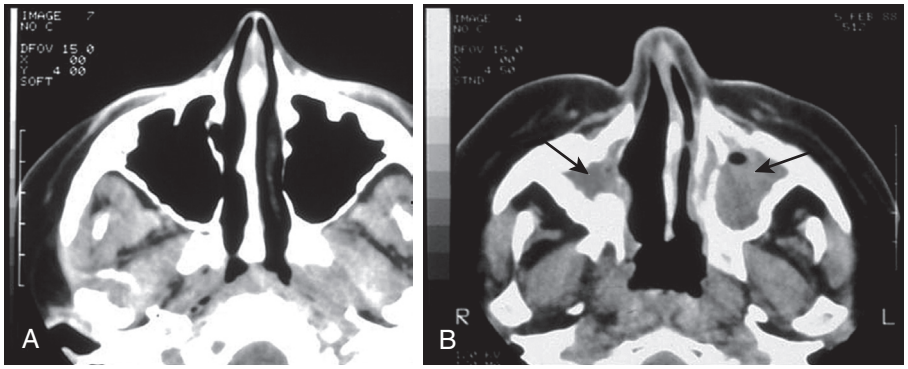

FIG. E5 Computed tomography (CT) scans of the sinuses. A, Normal maxillary sinuses in a recently diagnosed Wegener granulomatosis (WG) patient. **B,** Sinus CT scan of a patient with long-standing WG: Nasal septal deviation to the left, destruction of the medial walls of the right maxillary sinus, opacification of both sinuses with soft tissue densities *(arrows),* and neo-ossification of all maxillary bony structures due to chronic inflammation. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

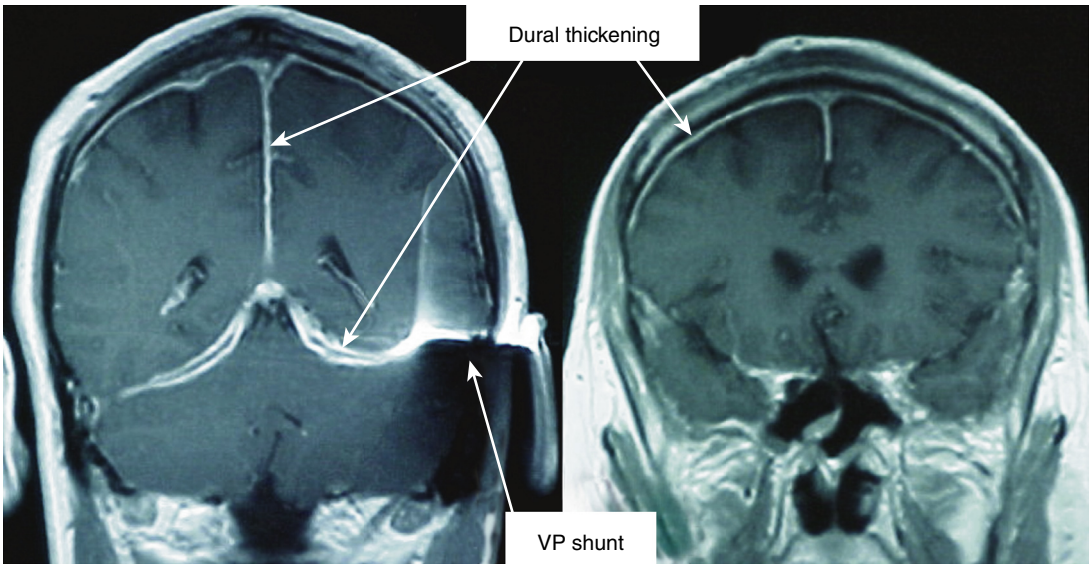

FIG. E6 Pachymeningitis in a patient with granulomatosis with polyangiitis. Magnetic resonance imaging findings. *VP,* Ventriculoperitoneal. (From Firestein GS et al: *Kelly's textbook of rheumatology*, ed 9, Philadelphia, 2013, WB Saunders.)

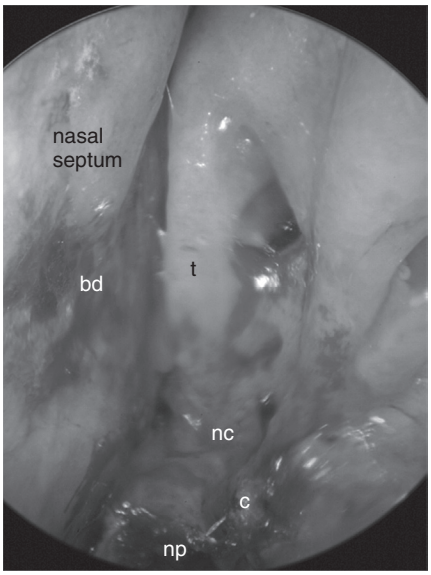

FIG. E7 Endoscopic view of nasal cavity of granulomatosis with polyangiitis patient showing crusting and bloody discharge. (From Holle et al: *Rheum Dis Clin North Am* 36[3]:507-526, 2010.)

- Maintenance therapy should generally be continued for at least 18 to 24 mo, and ultimate duration of immunosuppression is decided on a case-by-case basis.
- Treatment with TMP-SMX (160 mg/800 mg bid) may reduce the incidence of relapses in patients with granulomatosis with polyangiitis in remission. It is also useful in preventing *Pneumocystis jiroveci* pneumonia (PJP), which occurs in 10% of patients receiving induction therapy. Dose of TMP-SMX (160 mg/800 mg) for prophylaxis is 1 tablet three times/wk. If the patient is unable to tolerate TMP-SMX, PJP prophylaxis can also be achieved with dapsone, atovaquone, or inhaled pentamidine.

DISPOSITION

- Five-yr survival with aggressive treatment is approximately 80%; without treatment 2-yr survival is 20%.
- Age >50 yr, impaired renal function, pulmonary involvement at diagnosis, and lack of ENT changes at diagnosis are all associated with worse outcomes and increased mortality rate.
- With standard therapy, remission is achieved by 90% to 94% of patients, but relapse is frequent (from 18% to 40% at 24 mo).

REFERRAL

- Rheumatology referral for continued treatment
- ENT, surgical referral for biopsy

PEARLS & CONSIDERATIONS

COMMENTS

- Granulomatosis with polyangiitis is characterized by granulomatous lesions and vasculitis involving the respiratory tract, lung, and kidneys.
- C-ANCA levels should not dictate changes in therapy, because they correlate erratically with disease activity.
- The incidence of venous thrombotic events in patients with granulomatosis with polyangiitis is significantly higher than in the general population. Clinicians should maintain a heightened awareness of the risks of venous thrombosis and a lower threshold for evaluating patients for possible DVT or pulmonary embolism.
- Disease relapse remains a major problem in the course of the disease.

BASIC INFORMATION

DEFINITION

The prototype of granulomatous arthritis is tuberculous arthritis. Atypical mycobacteria, sarcoidosis, and sporotrichosis can cause granulomatous involvement of the synovium, but these entities are much less common.

SYNONYMS

Tuberculous arthritis
Pott disease

ICD-10CM CODES

M01.1 Tuberculous arthritis (A18.0+)
M01.6 Arthritis in mycoses (B35-B49+)
M01.8 Arthritis in other infections and parasitic diseases classified elsewhere
M00.9 Pyogenic arthritis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: No seasonal predilection
PREVALENCE (IN U.S.): Unknown
PREDOMINANT SEX: Male = female
PREDOMINANT AGE: Rare in childhood

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Often no constitutional symptoms (fever and weight loss)
- Possibly no clinical or radiographic evidence of pulmonary tuberculosis (TB)
- Spinal infection most often in the thoracic or upper lumbar area, with back pain as the most common symptom
- Considerable local muscle spasm possible
- Kyphosis and neurologic symptoms resulting from spinal cord compression in advanced disease
- Chronic monoarticular arthritis in the peripheral joints
- Single joint involved in 85% of patients
- Pain, swelling, limitation of motion, and joint stiffness less dramatic than in acute bacterial arthritis; possibly present for mos to yrs
- Seen more often in persons from developing countries, elderly patients, and hemodialysis patients

ETIOLOGY

- Hematogenous spread of organisms from a distant site of infection or by direct spread from bone
- Most commonly affected area: 50% of cases in the spine; next most commonly affected area: Large joints (knee and hip)
- Primary infection beginning in the lungs and spreading to the highly vascular synovium
- Tuberculous osteomyelitis commonly involving an adjacent joint
- In peripheral joints, a granulomatous reaction in the synovium causing joint effusion and eventual destruction of underlying bone
- In the spine, infection of the intervertebral disk spreading to adjacent vertebrae
- Osteomyelitis of vertebrae causing collapse, kyphosis, or gibbous deformity, and possibly paraspinal "cold" abscess

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Sarcoidosis
- Fungal arthritis
- Metastatic cancer
- Primary or metastatic synovial tumors

WORKUP

- High index of suspicion needed
- Gold standard: Synovial biopsy and culture for bacteria, including acid-fast bacilli, and fungi
- Joint aspiration and culture of the synovial fluid performed while awaiting biopsy
- Positive synovial fluid smear for acid-fast bacilli in 20% of cases; positive culture in 80%
- Elevated synovial fluid protein, low glucose
- Considerable variation in synovial fluid WBC count, but values of 10,000 to 20,000 cells/mm^3 typical; may be predominantly polymorphonuclear leukocytes
- Usually positive tuberculin skin test result implies exposure to TB, not necessarily active disease. Interferon-gamma release assays also can detect exposure to TB but not active disease (QuantiFERON TB Gold Test, TB T-Spot test)
- Anergy in elderly patients or in advanced disease
- In spinal infections, percutaneous or open biopsy to obtain accurate C&S data

LABORATORY TESTS

Peripheral WBC count and ESR are elevated but nonspecific.

IMAGING STUDIES

- Plain radiographs of the affected joint.
  1. Typically demonstrate bony destruction with little new bone formation
  2. Osteopenia and soft tissue swelling in early infections
  3. Later, erosions at the joint margins
  4. In the spine, disk space narrowing with vertebral collapse (wedging) causing characteristic kyphosis
- CT scan: Useful in early diagnosis of infections of the spine and to detect paraspinal abscess.
- Technetium and gallium scintigraphic scans: Findings may be positive but do not permit differentiation from inflammation or osteoarthritis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Encourage range of motion exercises of the affected joint to prevent contractures.

ACUTE GENERAL Rx

- Combination chemotherapy
  1. If sensitive TB suspected, give isoniazid 5 mg/kg/day (maximum 300 mg/day) plus rifampin 10 mg/kg/day (maximum 600 mg/day) for at least 6 mo and pyrazinamide 15 to 30 mg/kg/day (maximum 2 g/day) for at least the first 2 mo plus ethambutol 15 to 25 mg/kg/day until sensitivity results are available.
  2. Most patients are treated successfully with chemotherapy alone.
  3. Urgent surgical intervention is necessary if spinal cord compression causes neurologic changes.
- Surgical debridement in cases of extensive bone involvement

CHRONIC Rx

In long-standing extensive disease, arthrodesis of weight-bearing joints

DISPOSITION

Loss of cartilage and destruction of underlying bone if treatment is not initiated promptly

REFERRAL

- To a physician experienced in the management of TB
- For consultation with an infectious diseases specialist if drug resistance is suspected or documented
- For neurosurgical and/or orthopedic consultation if neurologic impairment suspected

PEARLS & CONSIDERATIONS

COMMENTS

As TB has become less prevalent in the U.S. in the past 10 yr, TB arthritis and osteomyelitis have also become less common. However, because of an increase in patients receiving antitumor necrosis factor-alpha therapy, there has been an increase of granulomatous diseases with nontuberculous mycobacteria such as *Mycobacterium avium.*

BASIC INFORMATION

DEFINITION

Graves disease is a hypermetabolic state caused by circulating immunoglobulin G (IgG) antibodies that bind to and activate the G-protein–coupled thyrotropin receptor. This activation stimulates follicular hypertrophy and hyperplasia, causing thyroid enlargement as well as increases in thyroid hormone production. It affects the thyroid, ocular muscles and shin. It is characterized by thyrotoxicosis, diffuse goiter, and infiltrative ophthalmopathy (edema and inflammation of the extraocular muscles and an increase in orbital connective tissue and fat); infiltrative dermopathy characterized by lymphocytic infiltration of the dermis; accumulation of glycosaminoglycans; and occasionally edema.

SYNONYM

Thyrotoxicosis

ICD-10CM CODES

E05.00	Thyrotoxicosis with diffuse goiter without thyrotoxic crisis or storm
E05.01	Thyrotoxicosis with diffuse goiter with thyrotoxic crisis or storm

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE/PREVALENCE: Graves disease is the most common cause of hyperthyroidism. It affects 3% of women and 0.5% of men during their lifetime. There is a slight increased incidence among young African Americans. The annual incidence of Graves disease-associated ophthalmopathy is 16 cases per 100,000 women and 3 cases per 100,000 men. It is more common in whites than Asians. Cigarette smoking is a risk factor.

PREDOMINANT AGE: Peak incidence is between 30 and 60 yr.

GENETICS: Patients often report a family history of Hashimoto thyroiditis, Graves disease, or other autoimmune conditions. Increased prevalence of *HLA-B8* and *HLA-DR3* in whites with Graves disease. Concordance rate is 20% among monozygotic twins.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Diffusely enlarged thyroid. Thyroid bruit may be present. Cervical lymphadenopathy may also be present
- Elevated systolic blood pressure with a widened pulse pressure
- Tachycardia, palpitations, tremor, hyperreflexia
- Exophthalmos (50% of patients) (Fig. 1), lid retraction (lid lag), in which contraction of the levator palpebrae muscles of the eyelids shows immobility of the upper eyelid with downward rotation of the eye
- Nervousness, weight loss (weight gain in 10% of patients), heat intolerance, pruritus, muscle weakness, atrial fibrillation
- Increased sweating, brittle nails, clubbing of fingers
- Localized infiltrative dermopathy (1% to 2% of patients) is most frequent over the anterolateral aspects of the legs, commonly over the pretibial area (pretibial myxedema) but can be found at other sites (especially after trauma). It is non-pitting and indurated. It is typically patchy with a peau d'orange appearance to the skin
- Men may have gynecomastia, reduced libido, and erectile dysfunction. Women often have irregular menses

ETIOLOGY

Autoimmune etiology: Thyrotropin receptor antibodies (TRAb) mediated activation of TSH receptor (TSHR). The activity of the thyroid gland is stimulated by the action of T cells, which induce specific B cells to synthesize antibodies against thyroid-stimulating hormone (TSH) receptors in the follicular cell membrane.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anxiety disorder
- Premenopausal state
- Thyroiditis
- Other causes of hyperthyroidism (e.g., toxic multinodular goiter, toxic adenoma)
- Other: Metastatic neoplasm, diabetes mellitus, pheochromocytoma

WORKUP

- The diagnosis is made clinically on most instances.
- The diagnostic workup includes a detailed medical history followed by laboratory and imaging studies and ECG. Patients often present with anxiety, heat intolerance, menstrual dysfunction, increased appetite, and weight loss. Elderly patients can have an atypical presentation (apathetic hyperparathyroidism). For additional information, refer to the topic "Hyperthyroidism."
- Table 1 describes the clinical assessment of the patient with Graves ophthalmopathy.

FIG. 1 Proptosis seen in the setting of Graves disease. A, Eye signs in Graves disease. **B,** Severe proptosis in Graves disease. (**A** and **B,** Courtesy Dr. Meir H. Kryger.) (From Kryger M et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.)

LABORATORY TESTS

- Increased free thyroxine (T_4) and free triiodothyronine (T_3)
- Decreased TSH
- Measurement of thyroid-stimulating antibodies (TSI) and TRAb

IMAGING STUDIES

- 24-hr radioactive iodine uptake (RAIU): Increased homogeneous uptake.
- CT or MRI of the orbits (Fig. E2) is useful if there is uncertainty about the cause of ophthalmopathy.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Patient education and discussion of therapeutic options.
- Smoking cessation: Smoking is associated with an increased risk of progression of Graves ophthalmopathy.

ACUTE GENERAL Rx

- Antithyroid drugs (thionamides, ATDs) to inhibit thyroid hormone synthesis or peripheral conversion of T_4 to T_3:
  1. Methimazole or propylthiouracil (PTU) are available. Methimazole is generally preferred because it has a longer half-life, allowing for once-daily dosing. PTU is preferred during pregnancy.
  2. Side effects: Skin rash (3% to 5%), arthralgias, myalgias, granulocytopenia (0.5%); rare side effects: Aplastic anemia, hepatic necrosis (PTU), cholestatic jaundice.
  3. Thionamide antithyroid drug therapy results in a remission in 40% to 50% of patients treated for 12 to 18 mo.
- Radioactive iodine (RAI):
  1. Treatment of choice for patients >21 yr and younger patients who have not achieved remission after 1 yr of ATD therapy
  2. Contraindicated during pregnancy and lactation
  3. Following radioactive therapy there may be an acute elevation of thyroid antibody titers and exacerbation of ocular symptoms in 15% to 20% of patients.
- Surgery: Near-total thyroidectomy. Indications: Obstructing goiters despite RAI and ATD therapy, patients who refuse RAI and cannot be adequately managed with ATDs, and pregnant women inadequately managed with ATDs. Complications of surgery include hypoparathyroidism (4%) and vocal cord paralysis (1%).
- Adjunctive therapy: Beta-adrenergic receptor blockers (e.g., atenolol 50 to 100 mg/day) to alleviate the beta-adrenergic symptoms of

TABLE 1 Clinical Assessment of the Patient with Graves Ophthalmopathy

Activity Measures*
Spontaneous retrobulbar pain
Pain on attempted up or down gaze
Redness of the eyelids
Redness of the conjunctiva
Swelling of the eyelids
Inflammation of the caruncle and/or plica
Conjunctival edema
Severity Measures
Lid aperture: Distance between lid margins in millimeters with the patient looking in the primary position, sitting relaxed, and with distant fixation
Swelling of the eyelids (absent/equivocal, moderate, severe)
Redness of the eyelids (absent/present)
Redness of the conjunctivae (absent/present)
Conjunctival edema (absent, present)
Inflammation of the caruncle or plica (absent, present)
Exophthalmos: Measured in millimeters using the same Hertel exophthalmometer and the same intercanthal distance for an individual patient
Subjective diplopia score†
Eye muscle involvement (ductions in degrees)
Corneal involvement (absent/punctate keratopathy/ulcer)
Optic nerve involvement: Best-corrected visual acuity, color vision, optic disk, relative afferent pupillary defect (absent/present), plus visual fields if optic nerve compression is suspected

*Based on the seven classic features of inflammation in Graves ophthalmopathy. The clinical activity score (CAS) is the total number of items present; a CAS ≥3 indicates active ophthalmopathy.
†Subjective diplopia score: 0 = no diplopia; 1 = intermittent (i.e., diplopia in primary position of gaze, when tired, or when first awakening); 2 = inconstant (i.e., diplopia at extremes of gaze); 3 = constant (i.e., continuous diplopia in primary or reading position).
From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders.

hyperthyroidism (tachycardia, tremor); contraindicated in patients with bronchospasm.

- Graves ophthalmopathy: Methylcellulose eye drops to protect against excessive dryness, sunglasses to decrease photophobia, intraocular and systemic high-dose corticosteroids for severe exophthalmos. Worsening of ophthalmopathy after RAI therapy is often transient and can be prevented by the administration of prednisone. Other treatment options include antiinflammatory and immunosuppressive agents, radiation, and corrective surgical procedures. The administration of the antioxidant selenium (100 μg PO bid) has been recently reported as effective in improving quality of life, reducing ocular involvement, and slowing progression of the disease in patients with mild Graves orbitopathy. Its mechanism of action is believed to be an effect on the oxygen free radicals and cytokines that play a pathogenic role in Graves orbitopathy. Inhibition of the insulin-like growth factor I receptor (IGF-IR) is a new therapeutic strategy to combat the underlying autoimmune etiology of ophthalmopathy. Trials with teprotumumab, a human monoclonal antibody inhibitor of IGF-IR, in patients with active, moderate-to-severe ophthalmopathy have shown effectiveness in reducing proptosis.[1]
- Dermopathy and acropachy: Topical corticosteroids are often used but are generally ineffective. Trials using rituximab infusion for dermopathy have shown striking improvement.

[1]Douglas RS et al: Teprotumumab for the treatment of active thyroid eye disease, N Engl J Med 382(4):341-352, 2020.

CHRONIC Rx

Patients undergoing treatment with ATDs should be seen every 1 to 3 mo until euthyroidism is achieved and every 3 to 4 mo while they are receiving ATDs.

DISPOSITION

- ATDs induce sustained remission in <60% of cases.
- The incidence of hypothyroidism after RAI is >50% within the first yr and 2% per yr thereafter.
- Complications of surgery include hypothyroidism (28% to 43% after 10 yr), hypoparathyroidism (4%), and vocal cord paralysis (1%).
- Successful treatment of hyperthyroidism requires lifelong monitoring for the onset of hypothyroidism or the recurrence of thyrotoxicosis.
- RAI therapy is followed by the appearance or worsening of ophthalmopathy more often than is therapy with methimazole, particularly in patients who are cigarette smokers. It can be prevented with the administration of prednisone 0.5 mg/kg body weight per day starting 2 to 3 days after RAI, continued for 1 mo, then tapered off over 2 mo.
- Mild to moderate ophthalmopathy often improves spontaneously. Severe cases can be treated with high-dose glucocorticoids, orbital irradiation, or both. Orbital decompression may be used in patients with optic neuropathy and exophthalmos (see "Hyperthyroidism").

Grief, Complicated or Prolonged

BASIC INFORMATION

DEFINITION

Bereavement is a universal human experience, and grieving after the loss of a loved one is recognized as a normal and healthy response to loss. Normal grieving typically resolves on its own over time. In a small proportion of bereaved individuals, the process of grieving does not resolve on its own. In complicated or prolonged grief, intense grieving symptoms significantly impair functioning. Complicated grief was proposed as a diagnosis for DSM-5, and prolonged grief disorder has been recommended for inclusion in the ICD-11. Persistent complex bereavement disorder is included in the DSM-5 appendix in the section for conditions needing further study.

SYNONYMS

Prolonged grief disorder
Persistent complex bereavement disorder

ICD-10CM CODES
Complicated grief and prolonged grief are not included as diagnoses in the DSM-5 or the ICD-10.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Studies indicate that of bereaved individuals, around 10% experience bereavement symptoms that grow or persist with the passage of time and significantly impair functioning.

PREDOMINANT SEX AND AGE: Prolonged grief is more common among women than men, and more common in the elderly, who are exposed to more losses as they age.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The key feature of prolonged or complicated grief is impaired functioning in occupational, social, or other contexts beyond 6 to 12 mo after the loss, with symptoms that center around feelings of loss. Individuals struggling with prolonged or complicated grief may present with intense longing for the deceased, feelings of emptiness, prolonged reactivity to reminders of the loss, unwillingness to adopt new roles, difficulty engaging in social relationships, isolation and social disengagement, and fixation on the past and on reminders of the past. They may have difficulty envisioning life without the deceased person and may experience suicidal ideation or intent as a result.

ETIOLOGY

The etiology is not known, but complications such as isolation or attentional biases impede normal resolution of grief and lead to prolonged or intensified grief symptoms. Risk factors include a history of trauma or loss, a history of mood or anxiety disorders, insecure attachment style, low perceived social support, increased stress, having been a caregiver for the deceased, pessimistic temperament, and violent cause of death of the deceased.

DIAGNOSIS

Proposed criteria for prolonged difficulties with bereavement differ, but commonalities include having been bereaved (loss of a loved one) and experiencing a constellation of the symptoms listed below for at least 6 mo (different sets of criteria propose different minimum lengths of time ranging from 6 to 12 mo):

- Experiencing intense yearning, sorrow, or pain, or preoccupation with the deceased
- Feeling stunned or having difficulty accepting the death of the loved one
- Feelings of emptiness or lack of self
- Emotional numbness
- Bitterness about the loss
- Avoidance of reminders of the loss
- Difficulty moving on with life and forging new friendships or pursuing hobbies or interests
- Difficulty engaging in relationships
- Difficulty imagining life without the deceased
- Impairment in social, occupational, or other areas of functioning

DIFFERENTIAL DIAGNOSIS

- Major depression: Whereas in major depression, wherein a globally pessimistic outlook prevails, with prolonged or complicated grief, negative feelings tend to be specifically centered on the loss of the loved one.
- PTSD: Whereas PTSD is characterized predominantly by fear, horror, anger, guilt, shame, and hyperarousal, prolonged or complicated grief is characterized by yearning, loss, and emptiness.

WORKUP

A comprehensive clinical interview should assess when symptoms began, whether symptoms and negative feelings center on the loss of the loved one, impairment in functioning, and hopelessness or suicidal ideation or intent. The assessment should also explore attachment history and the history or presence of other psychiatric disorders.

IMAGING STUDIES

Imaging studies have shown activation of the nucleus accumbens on exposure to cues of the deceased in cases of complicated grief but not in cases of normal grief.

TREATMENT

Studies have demonstrated the efficacy of various grief-specific therapies. Commonalities across treatments that have demonstrated efficacy include:

- Psychoeducation about grief
- A focus on processing the loss of the loved one, including feelings of loss and positive reminiscing about the loved one
- A focus on restoring functioning and purposeful engagement in life
- A focus on challenging thoughts that worsen negative feelings

Some studies have found that antidepressant medications are not effective for prolonged grief symptoms, but more research is needed on psychopharmacology and prolonged grief. For example, some studies report that a subset of bereaved individuals (20%) meet criteria for MDD and have a course and treatment response similar to nonbereaved patients with MDD. A recent study found that among suicide-bereaved individuals, complicated grief therapy enhances compliance with antidepressant medication, improves functioning, and reduces suicidal ideation.

Psychotherapies for depression, including interpersonal psychotherapy, have not been effective for prolonged or complicated grief.

DISPOSITION

Compared with normal grief, prolonged or complicated grief is associated with debilitating distress and disability, suicidal ideation, and negative health outcomes.

PEARLS & CONSIDERATIONS

- It is important to assess patients 6 to 12 mo after a loss of a loved one and to determine whether they might be experiencing prolonged or complicated grief.
- For patients with prolonged or complicated grief, grief-specific therapy has demonstrated efficacy and should be encouraged.
- Treatments for depression that do not specifically address the loss have not been shown to be effective for complicated grief.
- Suicidality must be assessed.

BASIC INFORMATION

DEFINITION

Guillain-Barré syndrome (GBS) is an acute immune-mediated polyradiculoneuropathy (affects nerve roots and peripheral nerves), with predominant motor involvement. It is the most common cause of acute flaccid paralysis in the Western hemisphere and probably worldwide. By definition, maximal clinical weakness, the clinical nadir, occurs within 4 wk of disease onset.

SYNONYMS

AIDP (acute inflammatory demyelinating polyradiculoneuropathy)
Acute polyneuropathy
Ascending paralysis
GBS
Postinfectious polyneuritis

ICD-10CM CODE
G61.0 Guillain-Barré syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 0.6 to 1.9 cases/100,000 persons annually without geographic variation. Incidence increases with age. A slight peak in incidence occurs between late adolescence and early adulthood. A slight male preponderance (1.25:1) also exists.

PREDISPOSING FACTORS: Viral (HIV, CMV, EBV, influenza) and bacterial *(Campylobacter jejuni, Mycoplasma pneumoniae)* infections; systemic illness (Hodgkin lymphoma, immunizations). Major antecedents of GBS are described in Box E1.

ETIOLOGY

- Unknown, but believed to be caused by infection-induced aberrant immune response.
- Preceding infectious illness 1 to 4 wk before disease onset has been noted. The most frequent antecedent infection is *C. jejuni* infection (associated with 30% of cases of GBS and 20% of cases of Miller Fisher syndrome).
- Humoral and cell-mediated immune attack of peripheral nerve myelin, Schwann cells; sometimes with primary axonal involvement.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symmetric weakness, most commonly involving proximal muscles initially, subsequently involving both proximal and distal muscles; difficulty in ambulating, getting up from a chair, or climbing stairs (Box E2)
- Depressed or absent reflexes bilaterally
- Minimal to moderate glove and stocking paresthesias/dysesthesia/anesthesia or back pain
- Pain (caused by involvement of posterior nerve roots) may be prominent
- Autonomic abnormalities (bradyarrhythmias or tachyarrhythmias, hypotension or hypertension)
- Respiratory insufficiency (caused by weakness of bulbar/intercostal muscles)
- Facial paresis, ophthalmoparesis, dysphagia (secondary to cranial nerve involvement)
- GBS consists of several clinical variants based on the pattern of clinical involvement and electrophysiologic findings. These include:
  1. AIDP (most common form in Europe and North America)
  2. Acute motor axonal neuropathy (AMAN; most prevalent form in China and Japan)
  3. Acute motor and sensory axonal neuropathy (AMSAN; has more severe sensory involvement and is associated with more severe clinical course and poorer prognosis)
  4. Miller Fisher syndrome (MFS; triad of ophthalmoplegia, ataxia, and areflexia)
  5. Acute pandysautonomia (rapid onset of parasympathetic and sympathetic failure without motor or sensory involvement)
  6. Regional variants (e.g., pharyngeal-cervical-brachial GBS, pure ataxic GBS)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Toxic peripheral neuropathies: Heavy metal poisoning (lead [microcytic anemia], thallium [alopecia], arsenic [typically accompanied by acute GI illness]), medications (vincristine, disulfiram), organophosphate poisoning, hexacarbon (glue sniffer's neuropathy)
- Nontoxic peripheral neuropathies: Acute intermittent porphyria, fulminant vasculitic polyneuropathy, infectious (poliomyelitis, diphtheria, Lyme disease, West Nile virus), tick paralysis
- Neuromuscular junction disorders: Myasthenia gravis, botulism, snake envenomation
- Myopathies such as polymyositis and acute necrotizing myopathies caused by drugs
- Metabolic derangements such as hypermagnesemia, hypokalemia, hypophosphatemia
- Acute CNS disorders such as basilar artery thrombosis with brainstem infarction, brainstem encephalomyelitis, transverse myelitis, or spinal cord compression
- Conversion disorder
- Malingering
- Table 1 differentiates clinical patterns of acute neuromuscular weakness

WORKUP

- Exclude other causes based on clinical history, examination, and laboratory tests.
- Lumbar puncture (may be normal in the first 1 to 2 wk of the illness). Typical findings include elevated CSF protein with few mononuclear leukocytes (albuminocytologic dissociation) in 80% to 90% of patients. Elevated CSF cell counts is an expected feature in cases associated with HIV seroconversion.
- EMG/nerve conduction study (NCS) may be normal in the first 10 to 14 days of the disease. The earliest electrodiagnostic abnormality is prolongation or absence of H-reflexes. NCS evidence of demyelination (prolonged distal latency, conduction velocity slowing, conduction block, temporal dispersion, and prolonged F-waves) in two or more motor nerves confirms diagnosis of AIDP in the appropriate clinical context.

LABORATORY TESTS

- CBC may reveal early leukocytosis with left shift. Electrolytes are tested to exclude metabolic causes of weakness.
- Heavy metal testing; urine porphyria screen; creatine kinase; HIV testing, including tests for HIV seroconversion, especially if CSF demonstrates lymphocytic pleocytosis. MRI brain and spinal cord with and without contrast may be indicated if diagnosis is uncertain. In GBS, a gadolinium-enhanced MRI of the lumbosacral spine may reveal nerve root enhancement.
- Antibodies against ganglioside GQ1b may be present in up to 90% of patients with MFS. IgG antibodies against ganglioside GM1 may be associated with AMAN. There are no antiganglioside antibodies commonly associated with AIDP.
- In equivocal cases, especially if peripheral nerve vasculitis is a concern, nerve biopsy may aid in confirming a diagnosis of GBS. Sensory nerve biopsy demonstrates segmental demyelination with infiltration of monocytes and T cells into the endoneurium. Axonal loss is commonly seen in sensory nerve biopsy specimens in GBS.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Close monitoring of respiratory function (frequent measurements of vital capacity, negative inspiratory force, and tidal volume) and pulmonary toilet should be done because respiratory failure is the major complication in GBS
- Frequent repositioning of patient to minimize formation of pressure sores
- Prevention of venous thromboembolism with antithrombotic stockings as a supplement to pharmacologic venous thromboembolism prevention
- Emotional support and social counseling for patient and family
- Pain control
- Cardiac monitoring to detect arrhythmias
- Physical and occupational therapy once patient is medically stable and able to participate.
- Avoidance of drugs that may worsen myasthenia gravis or interfere with neuromuscular transmission

ACUTE GENERAL Rx

- Option 1: Infusion of IV immunoglobulins (IVIG; 0.4 g/kg/day for 5 days). Always check serum IgA levels before infusion to prevent anaphylaxis in IgA-deficient patients.
- Option 2: Early therapeutic plasma exchange (TPE or plasmapheresis: 200 to 250 ml/kg over five sessions every other day), started within 7 days of onset of symptoms, is beneficial in reducing the need for mechanical ventilation in patients with rapidly progressive disease and results in improved rate of recovery. It is contraindicated in patients with cardiovascular disease (recent

TABLE 1 Clinical Patterns of Acute Neuromuscular Weakness

Cause	Cranial Nerve Involvement	Limb Weakness	Reflexes	Sensory	Autonomic Changes
Guillain-Barré syndrome	Common, facial diplegia	Distal (ascending)	Absent	Common	Possible (20%)
Miller Fisher syndrome	Hallmark: Ophthalmoplegia	Variable hallmark: Ataxia	Absent	Rare	Rare
Myasthenia gravis	Common, ptosis, facial, oculomotor	Proximal (shoulders and thighs)	Normal	Present	Present
Botulism	Symmetric diplopia, ptosis, dysarthria, dysphagia	Descending	Absent or decreased	No	Yes (e.g., ileus, mydriasis, reduced salivation, urinary retention)
Organophosphate poisoning	Bulbar dysfunction, dysarthria, dysphagia	Diffuse	Decreased	Late	Yes (e.g., bradycardia, sialorrhea, bronchorrhea, lacrimation, diarrhea, miosis causing blurry vision)
Brainstem	Common, ocular movement	Crossed findings (face/limbs)	Increased	Common	Rare
Spinal cord	No	Quadriparesis or paraparesis	Decreased then increased	Loss below level	If above thoracic level

From Parrillo JE, Dellinger RP: *Critical care medicine: principles of diagnosis and management in the adult*, ed 5, Philadelphia, 2019, Elsevier.

MI, unstable angina), active sepsis, and autonomic dysfunction.
- Both therapies are equally effective and may shorten recovery time by 50%. There is no proven benefit from combining IVIG and plasma exchange. Glucocorticoids are contraindicated.
- Mechanical ventilation may be needed if FVC is <12 to 15 ml/kg, vital capacity is rapidly decreasing or is <1000 ml, negative inspiratory force is <20 cm H_2O, PaO_2 is <70, or the patient is having significant difficulty clearing secretions or is aspirating.

CHRONIC Rx

- Ventilatory support may be necessary in 10% to 20% of patients. Adequate fluid/electrolyte support and nutrition are necessary, especially in patients with dysautonomia or bulbar dysfunction.
- Aggressive nursing care to prevent decubitus, infections, fecal impactions, and pressure nerve palsies.
- Monitoring and treatment of autonomic dysfunction (bradyarrhythmias or tachyarrhythmias, orthostatic hypotension, systemic hypertension).
- Treatment of back pain and dysesthesia with low-dose tricyclics, gabapentin, and so on. Opiate narcotics can be used cautiously in the short term but may compound dysautonomia.
- Pharmacologic venous thromboembolism prevention with agents such as heparin (5000 U SC q12h) or enoxaparin (40 mg SC daily) in poorly ambulating and nonambulatory patients.
- Stress ulcer prevention in patients receiving ventilator support.
- Physical and occupational therapy rehabilitation, including supportive devices.

DISPOSITION

- Mortality rate is approximately 5% to 10% worldwide. Causes of death include cardiac arrest, pulmonary embolism, and fulminant infections. A recent study showed 62% complete motor recovery, 14% mild weakness, 9% moderate weakness, 4% bed-bound or ventilated, and 8% dead at 1 yr. Another study suggested that about 33% of patients were free from sensory symptoms at 1 yr, with residual sensory loss present in the lower extremities in 67% and 36% in the upper extremities. About 32% had to change their work, 30% were unable to function at home as well as they could before the disease, and 52% had to alter their leisure activities 1 yr after GBS onset. Excessive fatigue is a common complaint in patients during the recovery phase of GBS. This may be treated with exercise therapy (e.g., bicycle exercise training).
- Predictors for poor recovery (inability to walk independently at 1 yr): Age >60 yr, preceding diarrheal illness, recent CMV infection, fulminant or rapidly progressing course, ventilatory dependence, reduced motor amplitudes (<20% normal), or unexcitable nerves on NCS. Outcomes may also be influenced by complications of medical therapy.
- GBS is typically a monophasic illness. Recurrence may occur in <5% of patients following full recovery.

REFERRAL

- Neurology to aid in diagnosis and direct treatment
- Pulmonary/critical care for ICU management
- Otolaryngology or general surgery for tracheostomy in patients requiring prolonged ventilatory support
- Gastroenterology for percutaneous endoscopic gastrostomy for patients with prolonged inability to obtain nutrition orally

PEARLS & CONSIDERATIONS

- GBS is the most common cause of acute flaccid paralysis.
- Close monitoring of ventilatory function with respiratory mechanics (FVC and NIF) is of paramount importance in all patients with suspected GBS.
- Glucocorticoids are not indicated in GBS and may even slow recovery.

PATIENT & FAMILY EDUCATION

Patient education information may be obtained from the Guillain-Barré Foundation International, The Holly Building, 104 1/2 Forrest Avenue, Narberth, PA 19072; phone: (610) 667-0131; fax: (610) 667-7036; toll-free: (866) 224-3301; E-mail: info@gbs-cidp.org

BOX E1 Major Antecedents of Guillain-Barré Syndrome

Frequent
Upper respiratory tract infections
Campylobacter jejuni enteritis
Cytomegalovirus infection
Epstein-Barr virus infection
Hepatitis A infection
Hepatitis B infection
Hepatitis C infection
HIV infection

Infrequent
Mycoplasma pneumoniae infection
Haemophilus influenzae infection
Leptospira icterohaemorrhagiae infection
Salmonellosis
Rabies vaccine
Tetanus toxoid
Bacille Calmette-Guérin immunization
Sarcoidosis
Systemic lupus erythematosus
Lymphoma
Trauma
Surgery

Questionable
Hepatitis B vaccine
Influenza vaccine
Hyperthermia
Epidural anesthesia

BOX E2 Findings Suggesting Guillain-Barré Syndrome

Relative symmetry of symptoms
Mild sensory signs and symptoms
Cranial nerve involvement
Autonomic dysfunction
Absence of fever at onset
Cytoalbuminologic dissociation of cerebrospinal fluid
Typical electrodiagnostic findings
Progression over days to wks
Recovery beginning 2 to 4 wk after cessation of progression

From Adams JG: *Emergency medicine: clinical essentials,* Philadelphia, 2013, Saunders.

Gynecomastia ALG PTG

BASIC INFORMATION

DEFINITION

Gynecomastia is a benign enlargement of male breast resulting from proliferation of glandular breast tissue.

ICD-10CM CODE
N62 Hypertrophy of breast

EPIDEMIOLOGY

- Most common reason for male breast evaluation.
- Seen in patients of all age groups.
- 60% to 90% of infants have transient gynecomastia due to high estrogenic state of pregnancy.
- Prevalence during adolescence ranges from 4% to 69%. It results from transient increase of estradiol concentration at the onset of puberty.
- Higher incidence in body builders due to use of anabolic steroids.
- 24% to 65% of older men have gynecomastia. It is secondary to decreased testosterone production with advanced age, increased peripheral conversion of testosterone to estrogen, and at times from side effects of medications.

PATHOPHYSIOLOGY

Altered estrogen-androgen balance, in favor of estrogen

ETIOLOGY

- Physiologic
- Infancy
- Puberty
- Persistent pubertal gynecomastia seen in 25% of cases
- Elderly
- Pathologic
- Idiopathic (25%)
- Increased estrogen production or action
- Testicular tumors (3%)
- Chronic liver disease
- Malnutrition
- Hyperthyroidism
- Adrenal tumors
- Familial gynecomastia
- Decreased testosterone production or action (10%)
- Testicular trauma
- Testicular torsion
- Viral orchitis
- Congenital anorchia
- Renal failure (1%)
- Hyperthyroidism (1.5%)
- Malnutrition
- Androgen insensitivity syndrome
- Five-alpha reductase deficiency
- Pituitary tumors
- Kallmann syndrome
- Klinefelter syndrome
- Medications (10% to 25%)
- Estrogen, gonadotropins, clomiphene, phenytoin, ketoconazole, metronidazole, metoclopramide, alkylating agents, busulfan, methotrexate, cisplatin, cimetidine, ranitidine, omeprazole, flutamide, finasteride, etomidate, HAART therapy, INH, tricyclic antidepressants, phenothiazines, diazepam, haloperidol, calcium channel blocker, ACE inhibitors, spironolactone, digoxin, amiodarone, methyldopa, alcohol, marijuana, heroin, methadone, amphetamine, anabolic steroids. Table E1 summarizes the various causes of gynecomastia.

CLINICAL FEATURES

- Although gynecomastia is usually bilateral, it could be unilateral.
- Characterized by concentric rubbery to firm disk of tissue, which is often mobile and located directly beneath the areola (Fig. E1).
- Pain is usually not severe. Varying degree of tenderness and nipple sensitivity are more common than pain, usually in the first 6 mo.

DIAGNOSIS

- Good history and physical examination including review of all medications the patient is taking is helpful.
- Mammogram is recommended for suspected breast cancer.

FIG. E1 Gynecomastia. (From Swartz MH: *Textbook of physical diagnosis*, ed 7, Philadelphia, 2014, Saunders.)

- Serum concentration of hCG, LH, testosterone, and estradiol should be measured, preferably in the morning, unless the cause is clearly apparent. There is no uniformity of opinion regarding what biochemical evaluation, if any, should be performed in patients with asymptomatic gynecomastia. Fig. E2 describes an algorithm for evaluation of gynecomastia.

DIFFERENTIAL DIAGNOSIS

- Breast cancer
  1. Mass is usually firm to hard
  2. Unilateral
  3. Eccentric in location
  4. Could be associated with nipple discharge and retraction, lymphadenopathy, and skin dimpling
- Pseudogynecomastia or lipomastia
  1. Characterized by fat deposition without glandular proliferation
  2. Seen in obese men
  3. Bilateral
  4. Remain unchanged over time

TREATMENT

- Observation is recommended for most patients with physiologic gynecomastia. They often regress spontaneously. Reassurance and follow-up examination in 3 to 6 mo usually suffice.
- Treat the underlying cause, and stop the offending medications.
- Treatment is most effective in the early stages (first 6 mo). Medical therapy often fails when given for longstanding (>12 mo) cases because of the presence of fibrosis.
- Potential indications of early therapy include severe breast enlargement, pain, tenderness, and psychological embarrassment. Consider giving tamoxifen 10 mg orally twice a day to these patients for up to 3 mo. It is not FDA-approved for this purpose. It results in regression of gynecomastia in approximately 80% of patients and, of which, only 60% had complete regression. As far as breast symptoms, such as pain and tenderness, some improvement is usually seen within a month of therapy.
- Surgery is offered for symptomatic gynecomastia that does not respond to medical therapy. However, for adolescents, surgery is deferred until puberty is completed. The different surgical options include subcutaneous mastectomy, ultrasound-guided liposuction, and suction-assisted lipectomy.
- For prevention of gynecomastia in patients with prostate cancer using antiandrogen therapy, one could offer tamoxifen or radiotherapy.

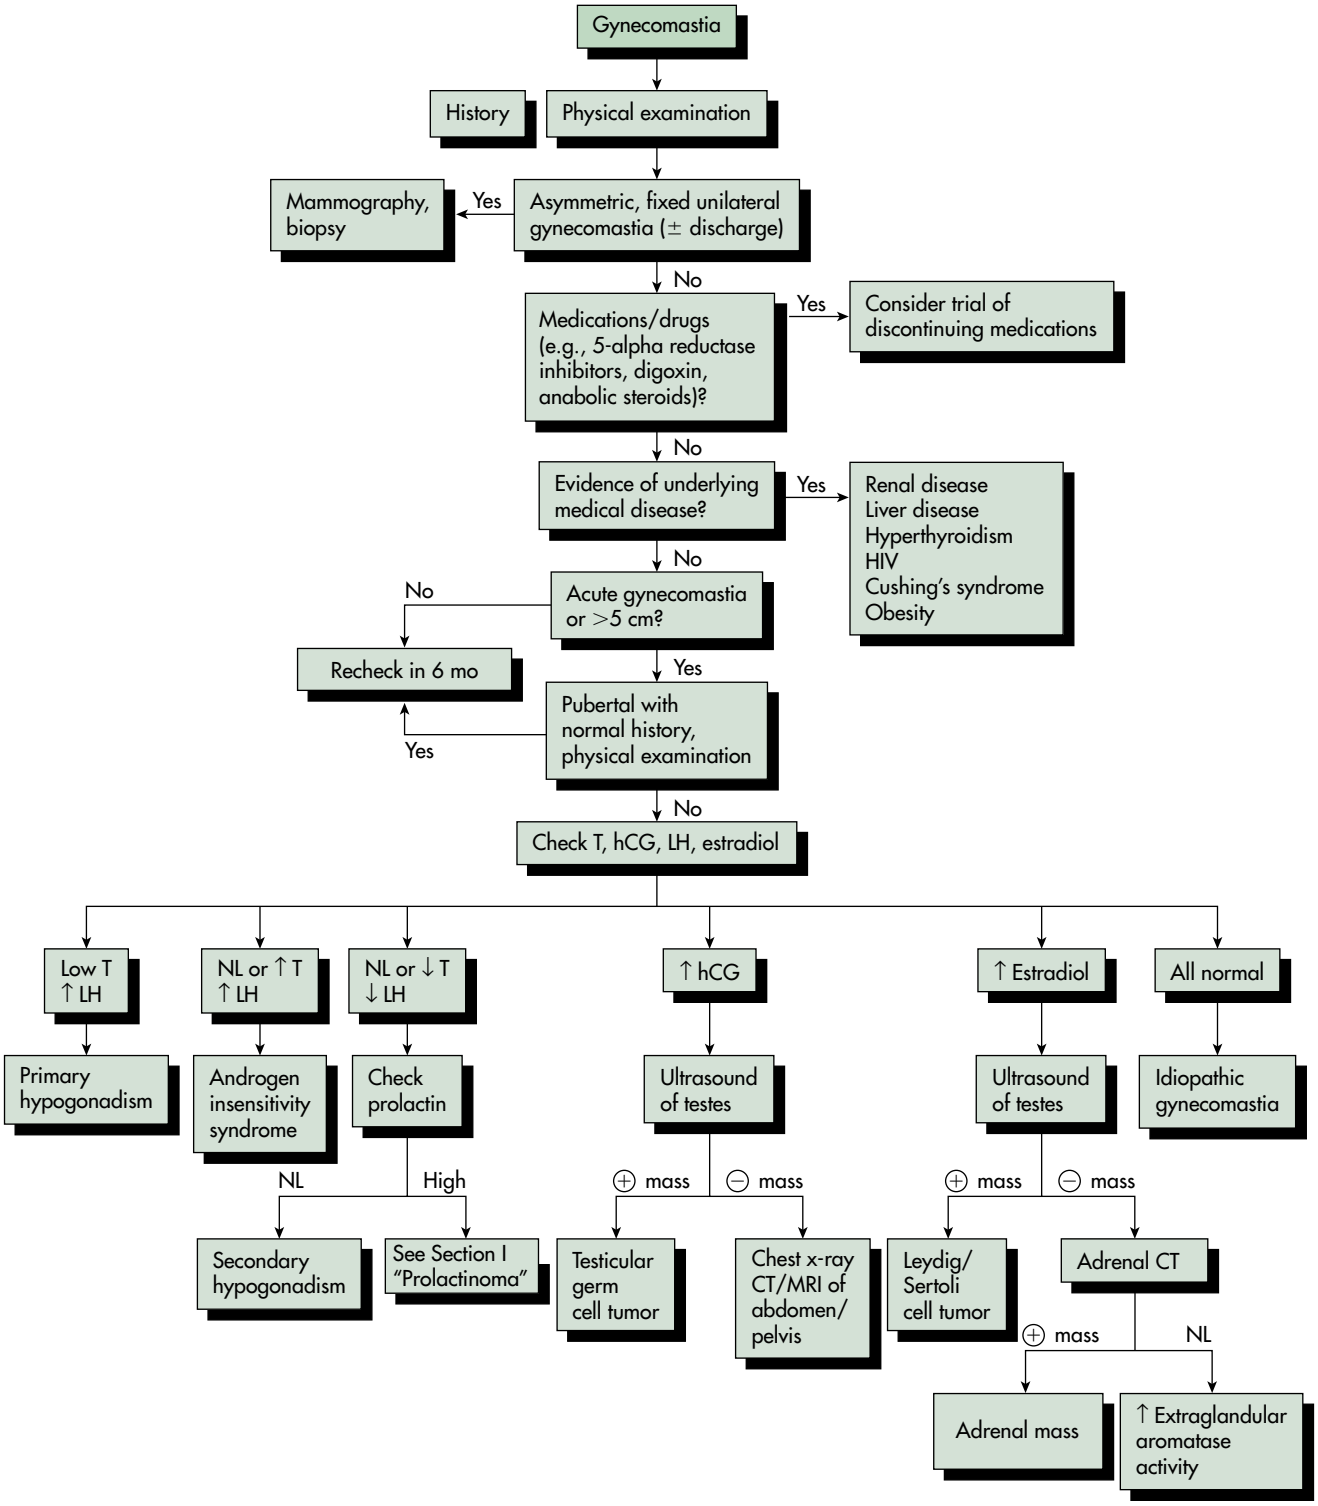

FIG. E2 Evaluation of gynecomastia. *CT,* Computed tomography; *hCG,* human chorionic gonadotropin; *HIV,* human immunodeficiency virus; *LH,* luteinizing hormone; *MRI,* magnetic resonance imaging; *NL,* normal limits; *T,* testosterone.

TABLE E1 Causes of Gynecomastia

Cause	Examples
Physiologic Causes	
Maternal estrogen exposure	Neonatal gynecomastia
Transient increase in estrogen to androgen concentrations	Pubertal gynecomastia
Estrogen Excess	
Estrogens or estrogen receptor agonists	Estrogens, marijuana smoke, digitoxin, testosterone or other aromatizable androgens
Increased peripheral aromatase activity	Obesity, aging, familial
Estrogen-secreting tumors	Adrenal carcinoma, Leydig or Sertoli cell tumor
hCG-secreting tumors	Germ cell, lung, hepatic carcinoma
hCG treatment	
Androgen Deficiency or Resistance	
Androgen deficiency	Primary or secondary hypogonadism
Hyperprolactinemia causing androgen deficiency	
Androgen resistance disorders	Congenital and acquired androgen resistance
Drugs that interfere with androgen action	Spironolactone, androgen receptor antagonists, marijuana, 5α-reductase inhibitors, histamine 2 receptor antagonists
Systemic Disorders	
Organ failure	Hepatic cirrhosis, chronic kidney disease
Endocrine disorders	Hyperthyroidism, acromegaly, growth hormone treatment, Cushing syndrome
Nutritional disorders	Refeeding, recovery from chronic illness (hemodialysis, insulin, isoniazid, antituberculous medications, ART)
Idiopathic Causes	
Drugs	ART, calcium channel antagonists, amiodarone, antidepressants (SSRIs, tricyclic antidepressants), alcohol, amphetamines, penicillamine, sulindac, phenytoin, omeprazole, theophylline
Adult-onset idiopathic gynecomastia	
Persistent prepubertal macromastia	

ART, Antiretroviral therapy; *hCG,* human chorionic gonadotropin; *SSRIs,* selective serotonin reuptake inhibitors.

BASIC INFORMATION

DEFINITION

Hairy cell leukemia is a lymphoid neoplasm characterized by diffuse infiltration of the spleen and bone marrow by small mature B cells with prominent cytoplasmic "hairy" projections.

SYNONYMS

HCL
Leukemic reticuloendotheliosis

ICD-10CM CODES

C91.40	Hairy cell leukemia not having achieved remission
C91.41	Hairy cell leukemia, in remission
C91.42	Hairy cell leukemia, in relapse

EPIDEMIOLOGY & DEMOGRAPHICS

- Rare disease with incidence of 3 cases per 1 million person-yr, about 900 new cases per yr in the U.S.
- Affects predominantly white men (male to female ratio of 4:1) with median age of 55 yr
- Accounts for about 2% of all leukemias in adults
- No known risk factors, although association with exposure to Agent Orange, industrial and agricultural chemicals has been suggested

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most patients present with fatigue and weakness, infections, or easy bruising.
- Physical findings include pallor, ecchymoses.
- Peripheral lymphadenopathy is uncommon.
- Splenomegaly due to infiltration by HCL is a salient feature present in >90% of cases (Fig. E1); hepatomegaly may be present in up to 58% (Table E1).
- Rarely, autoimmune complications (vasculitis, hemolytic anemia), extramedullary infiltration or spontaneous splenic rupture may occur.

ETIOLOGY

- HCL is a malignancy of mature B cells of unknown etiology.
- A molecular hallmark of HCL is the *BRAF* V600E gene mutation, which is present in almost all cases of HCL, but absent in other B-cell lymphomas.

DIAGNOSIS

The diagnosis of HCL requires demonstration of malignant B cells with characteristic immunophenotype and morphology in the blood, bone marrow and/or spleen. Table E1 describes major diagnostic features of HCL.

DIFFERENTIAL DIAGNOSIS

- Other lymphomas involving the spleen and bone marrow: Splenic marginal zone, follicular, or mantle cell lymphoma, CLL, as well as rare entities like HCL-variant and splenic diffuse red pulp small B-cell lymphoma. The distinction between HCL and these other disorders is facilitated by using the characteristic morphologic and immunotypic findings characteristic of these disorders (Table E2).
- HCL variant is a distinct entity characterized by worse prognosis, poor response to purine analogue chemotherapy, lack of *BRAF* mutation, lack of CD25 and CD123, expression of the *VH4-34* immunoglobulin rearrangement, and lymphocytosis.
- Myelofibrosis and bone marrow failure syndromes, including aplastic anemia.
- Other medical causes of splenomegaly and pancytopenia, including cirrhosis and type 1 Gaucher disease.

WORKUP (TABLE E3)

History and physical examination with attention to liver and spleen

LABORATORY TESTS AND IMAGING STUDIES (TABLE E4)

- Complete blood count shows pancytopenia; anemia may vary from minimal to severe; severe monocytopenia is characteristic.
- Peripheral blood smear for identification of hairy cells (Fig. E2) which can account for 5% to 80% of cells in the peripheral blood.
- Peripheral blood or bone marrow flow cytometry is necessary to rule out other lymphoproliferative disorders, including HCL-variant.
- A bone marrow biopsy (Fig. E3) is essential for diagnosis. Marrow aspiration may not be feasible because of increased reticulin fibrosis, resulting in a "dry tap."
- Pretreatment assessment of renal, liver function, lactate dehydrogenase and hepatitis B testing.
- Immunohistochemistry can detect the *BRAF* V600E mutation, but molecular testing for the mutation is recommended.
- Imaging is not essential, but computed tomography may be obtained to evaluate the spleen and internal adenopathy.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Asymptomatic patients with incidentally diagnosed HCL (10% of cases) may be observed without therapy.
- Fertility counseling is important prior to starting chemotherapy.

ACUTE GENERAL Rx

- HCL is typically treated with a single course of chemotherapy leading to a durable (median 8 yr) complete remission for up to 90% of patients. Blood counts typically normalize within 2 to 4 mo of treatment.
- Drugs of choice are the purine analogues: Cladribine (2-chloro-2-deoxyadenosine) or pentostatin (2-deoxycoformycin, DCF).
- Cladribine can be administered as an intravenous infusion or subcutaneous injection (0.10 to 0.14 mg/kg daily for 5 to 7 days, or weekly for 6 wk) and has little toxicity, except for the risk of neutropenic infections (20%) and septic death (2%). Patients with only partial remission may receive a second course at least 6 mo later.
- Infectious prophylaxis (*P. jirovecii* pneumonia, herpes zoster) may be used during immunosuppressive chemotherapy; G-CSF support does not decrease the risk of fever or hospitalization after standard therapy.
- Patients who have minimal residual disease after cladribine may receive additional treatment with the monoclonal antibody rituximab.
- A treatment algorithm for HCL is illustrated in Fig. E4.

CHRONIC Rx

- Patients require long-term follow-up and laboratory surveillance because approximately 40% eventually will experience a recurrence.
- Recurrent or refractory HCL may be treated with a repeat course of a purine analogue, rituximab, the anti-CD22 immunotoxin moxetumomab pasudotox, *BRAF* V600E inhibitors (vemurafenib or dabrafenib), interferon alpha, ibrutinib (oral Bruton tyrosine kinase inhibitor), or other chemotherapy.
- Survivorship principles include adherence to adult vaccination schedule (with the exception of live vaccines) and surveillance for secondary cancers (lymphomas, skin cancers, and some solid tumors).

DISPOSITION

HCL has a favorable prognosis with most patients achieving long-term survival.

REFERRAL

Hematology consultation is mandatory in all patients.

PEARLS & CONSIDERATIONS

COMMENTS

The diagnosis of hairy cell leukemia is occasionally missed and subsequently made by the pathologist after removal of the spleen for diagnostic purposes.

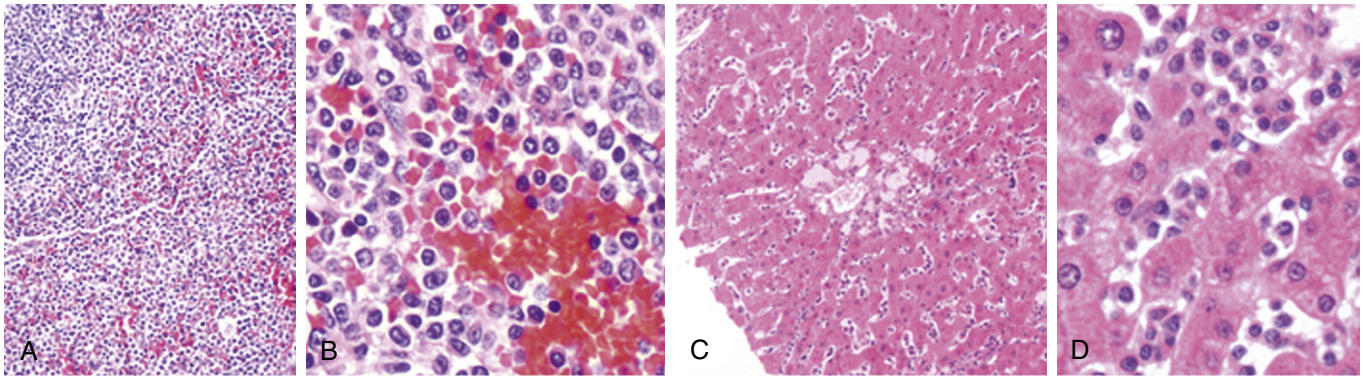

FIG. E1 Histopathology of the spleen and liver in hairy cell leukemia. The spleen **(A, B)** shows a massive and diffuse infiltrate in the red pulp and depletion of the white pulp. The infiltrate is associated with hemorrhage, which results in red blood cell "lakes" **(B)** (*lower right*). The liver **(C, D)** is frequently involved, and the pattern of infiltration is predominantly sinusoidal. (From Hoffman R et al: *Hematology: basic principles and practice*, ed 7, Philadelphia, 2018, Churchill Livingstone.)

TABLE E1 Major Diagnostic Features of Hairy Cell Leukemia

Study	Findings
Morphology of hairy cells	Oval or indented nuclei and abundant pale blue cytoplasm Absent or inconspicuous nucleoli Circumferential cell surface with "ruffled" projections
Bone marrow biopsy morphology	Diffuse or interstitial bone marrow infiltration, without discrete nodular aggregates Clear cells with "fried egg" or spindled appearance Reticulin fibrosis
Flow cytometry	Clonal B cells expressing CD11c, CD20, CD25, CD103, and CD200 and lacking CD5, CD10, and CD23 expression
Immunohistochemistry	Positive for cyclin D1, DBA.44, tartrate-resistant acid phosphatase (TRAP), and annexin-A1
Molecular studies	*BRAF* V600E mutation

Adapted from Jaffe ES et al: *Hematopathology,* Philadelphia, 2011, WB Saunders.

TABLE E3 Initial Workup of a Patient with Suspected Hairy Cell Leukemia

- History and physical examination
- Complete blood count with differential counts
- Review of peripheral blood smear
- Serum chemistries
- Bone marrow aspirate and biopsy with immunostains
- Immunophenotyping by flow cytometry of peripheral blood and bone marrow
- ? Serum soluble markers such as CD25 and CD22
- ? Immune status analysis with CD4/CD8 lymphocyte subsets
- Appropriate imaging, if febrile, to rule out infections

From Hoffman R, et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E4 Clinical and Laboratory Findings of Hairy Cell Leukemia at Presentation

Finding	% of Patients With Finding	Comments
Splenomegaly	86	Massive in 25% of patients
Hepatomegaly	73	If biopsied at presentation, the liver is nearly always involved.
Lymphadenopathy	13	Mostly abdominal and retroperitoneal; peripheral lymphadenopathy is uncommon.
Anemia (hemoglobin ≤12.0 g/dl)	77	
Neutropenia (1500×10^9/L)	79	
Monocytopenia (500×10^9/L)	98	Marked monocytopenia (150×10^9/L) is present in 90% of patients.
Thrombocytopenia ($100{,}000 \times 10^9$/L)	73	
Hairy cells detected on peripheral smear examination	85	Often few in number; identification may require careful examination by an experienced observer.

BASIC INFORMATION

DEFINITION

Hallucinations are false perceptions that have no basis in the external environment. Overdoses of hallucinogenic drugs cause symptoms including anxiety, dysphoria, tachycardia, fever, hypertension, seizure, and rhabdomyolysis. Commonly used drugs that cause hallucinations include lysergic acid diethyl amide (LSD), psilocybin (hallucinogenic mushrooms, "magic mushrooms"), mescaline, peyote, methylenedioxymethamphetamine (ecstasy), phencyclidine (PCP, angel dust), cathinone derivatives ("bath salts"), salvia, *Datura* genus (Jimson weed, angel's trumpet), dextromethorphan, and ketamine ("special K," "vitamin K").

SYNONYMS

Overdose, "OD"
Psychedelics
Entheigeon (substance that generates the god/spirit within)
Enactogens (awareness of "the touch within")

ICD-10CM CODES

F16.20	Hallucinogen dependence, uncomplicated
F16.90	LSD reaction (acute) (without dependence)
T40.901	A poisoning by unspecified psychodysleptics [hallucinogens], accidental (unintentional), initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Used by people of all ages. The drugs commonly are used in group settings such as raves, parties, and college events.
PEAK INCIDENCE: Most commonly between the ages of 17 and 25 yr old
PREVALENCE:

- LSD lifetime prevalence of use >12 yr old: 9.5%.
- Hallucinogens prevalence of use >12 yr old: 15.3%.
- Overdose or seeking medical treatment is rare.
- Table 1 (shows the prevalence of various drugs for 8th, 10th, and 12th graders in 2018.)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentation varies by amount and type of drug used.
- Overall presentation includes distortions in body image and sensory perception, as well as rapid, intense alterations in mood; emotions; and suggestibility.
- Overdose symptoms may range from acute anxiety, agitation, tachycardia, hypertension, hyponatremia, hyperthermia, severe agitation, rhabdomyolysis, seizure, cardiac dysrhythmia, respiratory failure, and death.
- Classic pure hallucinogens: Lysergic acid diethyl amide (LSD), psilocybin (hallucinogenic mushrooms, "magic mushrooms"). Individuals rarely present for medical treatment. The patient usually is conscious, alert, and can provide history of drug ingestion. Serious medical problems have been reported to include seizures, hyperthermia, rhabdomyolysis, and acute renal failure. New trends in self-administered "microdosing" of psilocybin or LSD for treatment of depression or other psychological disorders may present as inadvertent overdose.
- Mescaline: Found in many cacti. Similar structure to LSD; however, there have not been reports of medically significant adverse effects directly from the drug.
- Peyote: Legal for use by the Native American Church. Adverse effects occur first, prior to hallucinations, and within 1 hour of ingestion include severe nausea, vomiting, abdominal pain, dizziness, ataxia, nystagmus, and headache. Mild adrenergic effects of increased temperature, pulse, and blood pressure occurs after the initial symptoms. Hallucinations begin several hours later.
- Methylenedioxymethamphetamine (ecstasy): Not a true hallucinogenic but with similar effects of increased stimulation. Mild increase in temperature, pulse, hypertension, nausea, bruxism, jaw-clenching, dry mouth, muscle aches, ataxia. Severe effects include significant increases in blood pressure leading to intracranial hemorrhage, brain or heart ischemia, arrhythmia, sudden cardiac death, hyponatremia, malignant hyperthermia, DIC, seizures, and rhabdomyolysis. Symptoms are similar to serotonin syndrome.
- Phencyclidine (PCP, angel dust): Similar to ketamine with multiple effects that include features of hallucinations. Patients may have CNS stimulation or depression. The most common signs are mild hypertension and vertical nystagmus in 60% of patients. Other important warning signs for the safety of staff and physicians include severe agitation, physical violence, unpredictable behavior, and decreased response to pain. Disassociation, seizures (up to 3%), rhabdomyolysis with resulting acute renal failure, dystonic reactions, hyperthermia causing hepatic necrosis, and multiorgan failure are also possible.
- Cathinone derivatives (bath salts): Similar to PCP, with sympathomimetic effects of elevated temperature, blood pressure, pulse, sweating. Patients also may be severely agitated, aggressive, and violent toward staff. Severe medical effects include severe hyperthermia, hyponatremia, seizures, and rhabdomyolysis.
- Salvia: Adverse effects are mild and may include slurred speech, dysphoria, headache, nausea, vomiting, dizziness.
- *Datura* genus (Jimson weed, angel's trumpet): Anticholinergic alkaloids with symptoms consistent with anticholinergic poisoning: Hyperthermia, delirium, hallucinations, mydriasis, blurry vision, dry mouth, tachycardia, urinary retention.
- Dextromethorphan: Most commonly used by adolescents due to availability in over-the-counter cold and flu products; likely to be associated with salicylate, antihistamine, and acetaminophen overdose due to combination of cold and flu product ingredients.

ETIOLOGY

Usually caused by stimulation of various receptors in the brain, including serotonin type 2, dopamine, norepinephrine, acetylcholine, beta$_2$-adrenergic, NMDA, opioids, and voltage-gated electrolyte channels.

TABLE 1* Trends in Prevalence of Various Drugs for 8th Graders, 10th Graders, and 12th Graders; 2018 (in percent)

Drug	Time Period	8th Graders	10th Graders	12th Graders
Hallucinogens	Lifetime	2.20	3.90	6.60
	Past yr	1.40	2.70	4.30
	Past mo	0.60	0.80	1.40
Ketamine	Past yr	-	-	0.70
LSD	Lifetime	1.40	2.80	5.10
	Past yr	0.90	2.00	3.20
	Past mo	0.40	0.50	1.00
PCP	Past yr	-	-	1.10

LSD, Lysergic acid diethyl amide; *PCP,* phencyclidine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Alcohol use or withdrawal
- Benzodiazepine withdrawal
- Anticholinergic poisoning
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Thyrotoxicosis
- Central nervous system infections
- Anti-NMDA encephalitis
- Structural brain lesions
- Acute psychosis
- Hypoglycemia
- Hypoxia
- Sepsis
- Acute ischemic or hemorrhagic stroke
- Polysubstance use
- Incidental trauma

WORKUP

- Must rule out nontoxic causes of altered mental status. Vital signs should be examined immediately. History of drug use, dementia, delirium,

and risk factors for CNS infection should be considered. Patients should also be examined for occult and incidental trauma that occurred while under the influence of the drugs.

LABORATORY TESTS

- Consider:
  1. Complete blood count
  2. Glucose level
  3. Comprehensive metabolic panel
  4. Thyroid-stimulating hormone
  5. Creatine phosphokinase
  6. Arterial blood gas
  7. Toxicologic screening for other illegal drugs (urine and serum), acetaminophen, salicylate
  8. Lumbar puncture

IMAGING STUDIES

- Consider:
  1. ECG
  2. CT of head
  3. MRI of brain

Rx TREATMENT

Because most symptoms are not life or limb threatening, most treatment revolves around supportive treatment.

NONPHARMACOLOGIC THERAPY

- Place patient in a calm and quiet area with limited auditory and visual stimulation.
- Patients may benefit from a sitter to reorient him or her and provide a calming presence.
- Physical restraints should be used only if absolutely necessary due to the increased risk of agitation, hyperthermia, and rhabdomyolysis. Severely violent patients may require chemical restraint in addition to physical restraint.
- Severe hyperthermia may require active cooling measures.
- Supplemental oxygen should be considered.
- Bowel irrigation not usually recommended after 60 min of ingestion; unlikely to be beneficial for most compounds.

ACUTE GENERAL Rx

- Benzodiazepines are the mainstay of medical treatment
- Aggressive intravenous hydration with isotonic crystalloids
- Naloxone
- Dextrose
- Dantrolene if refractive hyperthermia
- Hypertonic saline if hyponatremic
- Cyproheptadine for serotonin syndrome
- IV nitroprusside or nicardipine for blood pressure control
- Propofol, barbiturate for refractive seizure
- Paralytics for hyperthermia secondary to dystonic reactions
- Physostigmine for severe anticholinergic poisoning

DISPOSITION

- Patients should be monitored for several hours for improvement of symptoms. If symptoms improve, patients who are mentally lucid and steady on their feet may be discharged under the close supervision of family or friends.
- Patients not improving may require further workup.
- If no organic cause is found, patients may require psychiatric evaluation.
- Patients may need to be admitted until resolution of organ injury.

REFERRAL

- Psychiatric referral may be required.
- Substance abuse or rehab.

PEARLS & CONSIDERATIONS

COMMENTS

- Actual substance used may be unclear.
- Most treatment is supportive care.
- Treat symptoms of hyperthermia, severe hypertension, and possible rhabdomyolysis.
- Chemical restraint with benzodiazepines is safe and effective.

BASIC INFORMATION

DEFINITION

Hand-foot-mouth disease (HFMD) is a viral illness characterized by superficial lesions of the oral mucosa and skin of the extremities. HFMD is primarily caused by coxsackie or enterovirus infection and can be transmitted by either respiratory droplet contact or fecal-oral contact. Although young children are predominantly affected, adults are also at risk. This disease is usually self-limited and benign, although outbreaks in the Asia Pacific region have been increasingly complicated by neurologic and cardiopulmonary sequelae.

SYNONYMS

HFMD
Vesicular stomatitis with exanthema
Coxsackie virus infection
Enterovirus infection

ICD-10CM CODE

B08.4	Enteroviral vesicular stomatitis with exanthem

EPIDEMIOLOGY & DEMOGRAPHICS

- HFMD most often affects children <10 yr.
  1. Children <5 yr are at the highest risk of infection and have the most severe cases.
- HFMD is contagious. Close contacts of affected children, including family members and health care workers, are the most commonly infected adults. Outbreaks can also occur in clustered populations of young adults (a recent outbreak at a military base affected 4.7% of the exposed population).
- Infection is spread from person to person by direct contact with saliva, respiratory secretions, fluid in vesicles, or stool.
- Outbreaks in daycares, schools, summer camps, hospital cohorts, and other groups with close contact are common.
- A person is most contagious during the first wk of illness.
- Outbreaks tend to occur during the summer.
- Infection leads to immunity, but a subsequent episode may occur after infection with a different etiologic virus or type.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms:

- After a 3- to 5-day incubation period (range 2 to 7 days), patients may report odynophagia, sore throat, malaise, and fever (38.3° to 40° C; 101° to 104° F).
- 1 to 2 days later, the characteristic oral lesions appear (small red spots that blister and may ulcerate). The fluid from these lesions is infectious, and disease can be transmitted through contact with the fluid.
- In 75% of cases, skin lesions on the extremities accompany these oral manifestations (small flat or raised red bumps, sometimes with blisters—they can be macular, maculopapular, or vesicular), but the lesions may be absent. The skin lesions are usually not painful or pruritic, but can be painful.
- Only 11% of adults have cutaneous findings.
- Lesions appear over the course of 1 or 2 days and resolve over 3 to 4 days.

Physical findings:

- Oral lesions are common and are usually found on the tongue, buccal mucosa, gingivae, and hard palate.
- Oral lesions initially start as 1- to 3-mm erythematous macules and evolve into gray vesicles on an erythematous base.
- Vesicles are frequently broken by the time of presentation and appear as superficial, gray ulcers with surrounding erythema.
- Skin lesions of the palms of the hands and soles of the feet are common and start as linear erythematous papules (3 to 10 mm in diameter) that evolve into gray vesicles that may be mildly painful (Fig. E1). These vesicles are usually intact at presentation and remain so until they desquamate within 2 wk. They are nonpruritic.
- Involvement of the buttocks and genital area is also common (present in 31% of cases).
- Although rare, atypical findings such as fingernail or toenail loss (nail separation from the nail matrix, otherwise known as onychomadesis) after HFMD (notably with the A6 strain of coxsackie virus) has been reported in children. The nail loss is temporary, and nails grow back without intervention.
- Another atypical skin manifestation is that of "eczema coxsackium," which is described as the typical skin lesions of coxsackie virus but with a more extensive distribution involving the trunk and extremities, localized to areas of active or past atopic dermatitis.
- In rare cases, encephalitis, meningitis, myocarditis, poliomyelitis-like paralysis, and pulmonary edema may develop. Sporadic acute paralysis and long-term neurologic sequelae have been reported with enterovirus 71.
- Although information is limited, there is no clear evidence that pregnancy outcomes are affected in the setting of maternal infection. There are case reports of potential adverse outcomes such as spontaneous abortion or serious neonatal morbidity attributed to coxsackie virus infection, although these outcomes are rare.

ETIOLOGY

- Coxsackie virus group A, type 16, was the first and is the most common cause of HFMD.
- Enterovirus 71 is the second leading cause of HFMD. Enterovirus 71 is neurotropic and has a predilection for the brainstem, leading to more severe cases of the disease and more complications than with other strains or viruses. Clusters of severe disease have been reported in the Asia Pacific region.
- Coxsackie virus strains A5, A6, A7, A9, A10, B1, B2, B3, and B5 have also been implicated.
- Coxsackie A6 has been known to cause a severe skin rash and self-limited nail abnormalities (onychomadesis). Patients with this strain may lack oral lesions.
- Epidemic outbreaks have been reported with coxsackie A16 and enterovirus 71.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Aphthous stomatitis
- Herpes simplex infection
- Herpangina
- Behçet syndrome
- Erythema multiforme
- Pemphigus
- Gonorrhea
- Acute leukemia
- Lymphoma
- Allergic contact dermatitis

WORKUP

The diagnosis is made on the basis of typical history and characteristic physical examination.

LABORATORY TESTS

- Not indicated unless the diagnosis is in doubt such as for a suspected case with an atypical presentation.
  1. Oropharyngeal specimen, stool specimen, or vesicular fluid may be obtained

FIG. E1 Hand-foot-mouth disease. Deep-seated vesicles with erythema involving the palmar surface of the fingers. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology: a textbook of skin disorders of childhood and adolescence*, ed 5, Edinburgh, 2016, Elsevier.)

to identify the presence of enterovirus or coxsackie virus by polymerase chain reaction (PCR) (preferred due to rapidity of results compared with culture) or by culture, but may take from 2 to 4 wk for results. Due to prolonged shedding of the virus (wks to mos), detection of virus in secretions may not be responsible for current symptoms.

- Identification of a certain strain is only available in public health laboratories.

Rx TREATMENT

ACUTE GENERAL Rx

- Symptomatic therapy is given for this usually self-limited disease and usually resolves completely within 7 to 10 days.
- There are currently no available approved therapies for more severe cases. Antivirals and IV immunoglobulin have been evaluated for enterovirus 71 infections, but these treatments have not been evaluated in randomized, placebo-controlled studies.
- Systemic steroids should be avoided because they have been associated with more severe disease and higher viral loads.

DISPOSITION

Prognosis is excellent except in rare cases of central nervous system or cardiac involvement. Most are managed as outpatients. Hospitalization should be considered if the patient is unable to maintain adequate hydration due to painful oral lesions and in cases of neurologic manifestations such as meningitis, encephalitis, or flaccid paralysis, or cardiac complications such as myocarditis.

REFERRAL

Not usually needed, although dermatology or infectious disease consultation can be considered for diagnostic or therapeutic input for an atypical or severe case

PEARLS & CONSIDERATIONS

- Frequent handwashing, disinfection of contaminated surfaces, and washing of soiled articles of clothing can help reduce transmission.
- HFMD has no relation to hoof and mouth disease in cattle.

BASIC INFORMATION

DEFINITION

Hantavirus pulmonary syndrome (HPS) is a severe infectious cardiopulmonary illness usually caused by the Sin Nombre virus (SNV), whose main vector is the deer mouse.

SYNONYMS

Four Corners disease
Hantavirus cardiopulmonary syndrome (HCPS)
HPS

ICD-10CM CODE
B33.4 Hantavirus (cardio)-pulmonary syndrome (HPS) (HCPS)

EPIDEMIOLOGY & DEMOGRAPHICS

- First identified in the U.S. in 1993, hantavirus has been found throughout the Americas, with most U.S. cases occurring in the Western half of the U.S.
- The number of HPS cases reported in the U.S. through December 31, 2012, was 616. Of these, 585 cases occurred from 1993 onward, following the initial identification of HPS, whereas 31 cases were retrospectively identified. 36% of all reported cases have resulted in death.
- The peak incidence to date was in June and July 1993 in the Four Corners region of the U.S.
- HPS is more common in the spring and summer.
- HPS is more prevalent among males, most likely because of increased environmental exposure.
- Mean age is 37 yr (range, 8 to 83). It has not been found at the extremes of age.
- Risk factors include exposure to rodent populations, rural locales, occupations with increased exposure to rodents, and entering infrequently opened structures.

CLINICAL PRESENTATION

- The most common symptoms are fever, headache, nausea, vomiting, cough, shortness of breath, and myalgia. It is not associated with rhinorrhea or nasal congestion.
- The most common signs on physical examination include fever, hypoxemia, and tachypnea. Rash, mucosal bleeding, and peripheral edema are not found with HPS.
- There are two phases of HPS, the prodromal phase and the cardiopulmonary phase, each of which lasts 2 to 7+ days. The prodromal phase is characterized by:
  1. Fever, chills, headache, and myalgias, especially in the legs and back
  2. Cough, nausea, vomiting, diarrhea, abdominal pain, and general malaise
  3. Tachypnea, tachycardia, and hypoxemia
- The cardiopulmonary phase has the following characteristics:
  1. Dry cough and dyspnea
  2. Acute pulmonary edema
  3. Hypotension
  4. Decreased cardiac output
  5. Coagulopathy

ETIOLOGY

- HPS is most often caused by SNV.
- The main vector is the deer mouse.
- It is transmitted by inhalation of aerosolized feces, urine, or saliva from infected rodents.
- No cases of person-to-person transmission have been reported in the U.S.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute respiratory distress syndrome
- Pneumonia, especially atypical
- Congestive heart failure
- Pulmonary edema
- Acute bacterial endocarditis
- Gastroenteritis, appendicitis, or cholelithiasis
- Plague
- Tularemia ("rabbit fever")
- Histoplasmosis
- Coccidioidomycosis
- Cardiogenic shock
- HIV/AIDS
- Myocardial infarction
- Goodpasture syndrome or granulomatosis with polyangiitis (Wegener granulomatosis)
- Other viral hemorrhagic fevers (see Table E1)

TABLE E1 Pathobiologic and Clinical Aspects of Viral Hemorrhagic Fevers

Disease	Incubation Period (days)	Onset	Bleeding	Rash	Jaundice	Heart	Lung	Kidney	CNS	Eye

CNS, Central nervous system; *HF,* hemorrhagic fever; 0, sign not typically noted/organ not typically affected; +, sign occasionally noted/organ occasionally affected; ++, sign commonly noted/organ commonly affected; +++, sign characteristic/organ involvement severe.
[a]Data are insufficient to distinguish between the syndromes produced by the various Old and New World arenaviruses.
[b]Hemorrhagic fever, encephalitis, and retinitis may be seen in Rift Valley fever independently of each other.

WORKUP

- Diagnosis is made on the basis of clinical criteria (fever, hypoxemia, and bilateral interstitial edema) or autopsy evidence of idiopathic noncardiogenic pulmonary edema, as well as confirmatory laboratory testing.
- Laboratory testing: Rapid strip immunoblot assay (RIBA), Western blot, or ELISA to detect IgM antibodies to SNV or other hantaviruses.
- Complete blood count q8h initially.
  1. All patients manifest thrombocytopenia, and its progression is the most consistent indicator heralding the cardiopulmonary phase of HPS.
  2. Differential usually reveals a left shift with atypical, enlarged lymphocytes. White blood cell counts are an unreliable indicator of severity of infection.
- Lactate level >4 mg/dl is associated with a high mortality rate.
- Elevated serum LDH level.
- Rapid immunoblot strip assay for SNV antibodies.
- Diagnosis is confirmed by identification of immunoglobulin M and G antibodies to SNV.

IMAGING STUDIES

Chest radiography: Bilateral diffuse interstitial edema

Rx TREATMENT

There is no known specific treatment or therapy, only supportive therapy.

NONPHARMACOLOGIC THERAPY

- Intensive care unit admission in tertiary care center
- Mechanical ventilation with high pulmonary end-expiratory pressure and high Fio_2
- Pulmonary artery catheterization
- Extracorporeal membrane oxygenation (ECMO)

ACUTE GENERAL Rx

- Supportive measures
- Supplemental oxygen
- Intubation when indicated
- Hemodynamic monitoring
- Cautious fluid resuscitation because of potential capillary leak syndrome
- Early use of vasopressors
- Initial broad-spectrum antibiotics
- No definitive antiviral therapy for SNV
- Glucocorticoids have no effect on reducing mortality and therefore cannot be recommended

DISPOSITION

- Patients who survive cardiopulmonary phase of HPS have rapid clinical improvement.
- There are no serious sequelae.

REFERRAL

University of New Mexico Hospital is one of the few facilities with experience in ECMO for treatment of HPS. This modality is only for hemodynamically unstable, critically ill patients who do not respond to conventional therapies.

BOX E1 Centers for Disease Control and Prevention Recommendations for Preventing Hantavirus Pulmonary Syndrome

- Eliminate rodent harborage.
  1. Keep cooking, eating, and food storage areas clean.
  2. Cover human food and animal feed.
  3. Contain and elevate garbage.
  4. Seal holes and cracks in dwellings to prevent entrance by rodents.
  5. Clear brush and trash from around homes and outbuildings.
- Control rodent populations by maintaining snap traps and using rodenticides; in areas where plague occurs, control fleas with insecticides.
- Safely clean up rodent-infested areas.
  1. Air out infested spaces before cleanup.
  2. Spray areas of infestation and all excreta, nesting, and other materials with household disinfectant or 10% bleach solution. Then clean up, seal in bags, and dispose.
  3. Avoid sweeping, vacuuming, or stirring dust until the area is thoroughly wet with disinfectant.
  4. Wear rubber gloves; disinfect gloves before removal, and wash hands afterward.
  5. In areas where plague occurs, spray insecticide on trapped rodents and nesting materials to prevent fleas from abandoning rodents to find new hosts.
- Avoid rodents when outdoors.
  1. Do not disturb rodent droppings or camp or sleep near burrows or areas where trash is present.
  2. Avoid feeding or handling rodents even if they appear friendly.

From Auerbach P: *Wilderness medicine, Expert Consult premium edition—enhanced online features and print,* Philadelphia, 2012, WB Saunders.

PEARLS & CONSIDERATIONS

COMMENTS

- Although rare, HPS should be a consideration in those with acute respiratory illness and a history suggestive of HPS exposure. The combination of thrombocytopenia, left shift granulocytes, and circulating immunoblasts >10% of the total lymphoid series (diagnostic triad) is rare in other viral illnesses.
- Testing for hantavirus should always be considered in cases of thrombocytopenia and fever of unknown origin, especially in areas endemic for the infection.

PREVENTION

Rodent control is the primary way to prevent hantavirus infection. Box E1 describes CDC recommendations for preventing hantavirus pulmonary syndrome. No prophylactic vaccine is available.

AUTHOR: **Maher Tabba, MD, FACP, FCCP**

SUGGESTED READINGS

Centers for Disease Control and Prevention: Reported cases of HPS: HPS in the United States. Available at: www.cdc.gov/hantavirus/surveillance/index.html.

Denecke B et al: Hantavirus infection: a neglected diagnosis in thrombocytopenia and fever? *Mayo Clin Proc* 85(11):1016-1020, 2010.

BASIC INFORMATION

DEFINITION

Head and neck squamous cell carcinoma is a malignant disease entity that arises from the epithelium of the mucosal surfaces of the upper aerodigestive tract and accounts for about 90% of head and neck cancers. This disease results from exposure to carcinogens and from the accumulation of genetic alterations. The workup and management of these patients depends upon the specific subsite of the aerodigestive tract in the head and neck from which the primary tumor arises. These subsites are the oral cavity, oropharynx, nasopharynx, hypopharynx, and larynx. Cutaneous malignancies, thyroid neoplasms, and salivary gland neoplasms also occur in the head and neck but are beyond the scope of this chapter.

SYNONYMS

HNC
Head and neck cancer
HNSCC
Head and neck squamous cell carcinoma

ICD-10CM CODES

C00-C14	Malignant neoplasms of lip, oral cavity, and pharynx
C30	Malignant neoplasm of nasal cavities, middle ear, and accessory sinuses
C32	Malignant neoplasm of larynx
C77.0	Secondary and unspecified malignant neoplasm of lymph nodes of head, face, and neck

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- U.S. annual incidence of head and neck cancer (90% of which is squamous cell carcinoma) is approximately 62,000 persons per yr.
- Annual mortality is approximately 13,000 persons per yr.
- Accounts for approximately 3% of all cancers in the U.S.
- Human papilloma virus (HPV)-associated squamous cell carcinoma of the head and neck accounts for 5% to 20% of all HNSCCs, and 40% to 90% of those arise in oropharynx.
- Incidence of all forms of HNSCC is on the decline, except oropharyngeal squamous cell carcinoma, which is increasing in incidence, likely related to the rise in human papilloma virus (HPV) associated HNSCC.

PEAK INCIDENCE: Sixth decade of life

PREDOMINANT SEX AND AGE: Male:female ratio is about 3:1. Risk increases significantly over the age of 40.

GENETICS: Research is ongoing in genetic factors that lead to the development and progression of HNSCC. Tumor suppressor genes including *p53, NOTCH1,* and *CDKN2A,* among others, have been shown to harbor mutations in patients with HNSCC.

RISK FACTORS: The two most strongly implicated risk factors associated with HNSCC are tobacco and alcohol use. These carcinogens place the entire epithelium of the upper respiratory tract at risk for multiple primary tumors via a process known as field cancerization. More recently, a new subset of HNSCC caused by the HPV has been increasing in prevalence. HPV 16 is the most common genotype detected. Patients are more likely to be white middle-aged men, nonsmokers, with minimal alcohol use and higher socioeconomic status.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presenting signs and symptoms are related to local effects of the primary tumor, regional spread, metastatic disease, or paraneoplastic phenomena:
  1. Oral cavity, oropharynx, hypopharynx: Painful mass or ulceration (Fig. E1), dysphagia, odynophagia, weight loss
  2. Larynx: Hoarseness, voice change, shortness of breath, stridor
  3. Nasal cavity, paranasal sinus, nasopharynx—referred otalgia, conductive hearing loss from middle ear effusion, epistaxis, cranial nerve palsies
  4. All sites: Cranial nerve palsies, painless neck mass from regional metastases to cervical lymph nodes. Most common site of distant metastases is the lung, with bone and liver being much less common
- Physical exam: A thorough examination of the head and neck, including cranial nerve exam, otoscopy, inspection and palpation of oral cavity, oropharynx, and neck, and general physical exam:
  1. Concerning exam findings: Unilateral middle ear effusion, ulcerated mass of the oral cavity (Fig. E2) or oropharynx, trismus, painless neck mass

ETIOLOGY

Exposure to carcinogens including tobacco and alcohol causes genetic alterations in the epithelium of mucosal surfaces lining the upper aerodigestive tract, leading to malignant transformation of epithelial cells. HPV-associated HNSCC is a direct result of the carcinogenic effects of the virus and is not related to alcohol and tobacco use. Primary nasopharyngeal carcinoma has a weak association with tobacco and alcohol and is endemic to southern China, Southeast Asia, and northern Africa. There is a strong association between Epstein-Barr virus infection and primary nasopharyngeal carcinoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Lymphoma, primary salivary gland malignancy, thyroid malignancy, benign tumors of the upper aerodigestive tract, metastases

WORKUP

- Initial workup includes a full physical examination, indirect and/or direct laryngoscopy, imaging studies of the head and neck as well as the chest and/or body to assess for metastases, laboratory tests as indicated, and referral to a head and neck cancer specialist.
- Additional workup by head and neck cancer specialist:
  1. Flexible fiber-optic laryngoscopy or mirror laryngoscopy
  2. Biopsy of the tumor in office or under anesthesia
  3. Fine-needle aspiration (FNA) and biopsy for patient who presents with a suspicious neck mass
  4. Panendoscopy with biopsy under anesthesia, which may include direct laryngoscopy, esophagoscopy, and/or bronchoscopy

LABORATORY TESTS

Complete blood count (CBC), coagulation studies, electrolytes, ECG, liver function tests (albumin, transaminases, alkaline phosphatase), TSH

IMAGING STUDIES

- CT scan of the neck with contrast: Necessary to evaluate extent of primary tumor and nodal metastases in neck (Fig. E3)
- MRI of head and neck (optional): Useful for nasopharyngeal, infratemporal fossa, temporal bone, parotid, parapharyngeal, skull base, or intracranial involvement
- Chest x-ray or CT chest with contrast: To evaluate for lung metastases
- PET/CT (Fig. E4): Highlights areas in the body with increased metabolic uptake. Useful initially to assess extent of primary tumor, location of unknown primary tumor, cervical metastases, distant metastases, and second primary tumors. Can be used to monitor for recurrence in the posttreatment setting

STAGING

Staging is based on the tumor, node, metastasis (TNM) staging system provided by the AJCC (Table 1). Staging varies depending on the head and neck subsite that is involved. Any nodal metastasis in the neck automatically classifies as advanced disease (Stage III or IV). Distant metastases place patients at Stage IVC. The exception to this is HPV-positive cancer of the oropharynx, in which the most recent staging system allows for a patient to be classified as low as Stage II even with cervical nodal metastases given the excellent response to treatment and prognosis for these tumors.

TREATMENT

- Treatment consists of surgery, radiation, chemotherapy, or a combination of any or all of the three modalities. The goal is to use as few modalities as possible to minimize side effects of treatment without compromising oncologic success.
  1. Surgery (Fig. E5): Complete surgical resection of the primary tumor along with unilateral or bilateral neck dissections to

TABLE 1 TNM Staging System for Cutaneous Squamous Cell Carcinoma of the Head and Neck

T: Primary Tumor

T_X	Primary tumor cannot be assessed
T_{is}	Carcinoma in situ
T_1	Tumor <2 cm in greatest dimension
T_2	Tumor ≥2 cm, but <4 cm in greatest dimension
T_3	Tumor ≥4 cm in maximum dimension or minor bone erosion or perineural invasion*
T_4	Tumor with gross cortical bone/marrow, skull base invasion and/or skull base foramen invasion
T_{4a}	Tumor with gross cortical bone/marrow invasion
T_{4b}	Tumor with skull base invasion and/or skull base foramen involvement

*Deep invasion is defined as invasion beyond the subcutaneous fat or >6 mm (as measured from the granular layer of adjacent normal epidermis to the base of the tumor); perineural invasion for T_3 classification is defined as tumor cells within the nerve sheath of a nerve lying deeper than the dermis or measuring ≥0.1 mm in caliper, or manifesting with clinical or radiographic involvement of named nerves without skull base invasion or transgression.

N: Regional Lymph Nodes

Clinical N (cN)

N_X	Regional lymph nodes cannot be assessed
N_0	No regional lymph node metastasis
N_1	Metastasis in single ipsilateral lymph node, ≤3 cm in greatest dimension and ENE(–)
N_2	Metastasis in single ipsilateral lymph node, >3 cm but not >6 cm in greatest dimension and ENE(–); or in multiple ipsilateral lymph nodes, none >6 cm in greatest dimension; or in bilateral or contralateral lymph nodes and ENE(–), none >6 cm in greatest dimension and ENE(–)
N_{2a}	Metastasis in single ipsilateral lymph node, >3 cm but no >6 cm in greatest dimension and ENE(–)
N_{2b}	Metastasis in multiple ipsilateral lymph nodes, none >6 cm in greatest dimension and ENE(–)
N_{2c}	Metastasis in bilateral or contralateral lymph nodes, none >6 cm in greatest dimension and ENE(–)
N_3	Metastasis in lymph node, >6 cm in greatest dimension and ENE(–); *or* metastasis in any node(s) and clinically overt ENE [ENE(+)]
N_{3a}	Metastasis in a lymph node >6 cm in greatest dimension and ENE(–)
N_{3b}	Metastasis in any node(s) and ENE(+)

Pathologic N (pN)

N_X	Regional lymph nodes cannot be assessed
N_0	No regional lymph node metastasis
N_1	Metastasis in single ipsilateral lymph node, ≤3 cm in greatest dimension and ENE(–)
N_2	Metastasis in single ipsilateral lymph node, ≤3 cm in greatest dimension and ENE(+), or >3 cm but not >6 cm in greatest dimension and ENE(–); or metastases in multiple ipsilateral lymph nodes, none >6 cm in greatest dimension and ENE(–); or in bilateral or contralateral lymph nodes, none >6 cm in greatest dimension and ENE(–)
N_{2a}	Metastasis in single ipsilateral lymph node, ≤3 cm in greatest dimension and ENE(+), *or* a single ipsilateral node >3 cm but not >6 cm in greatest dimension and ENE(–)
N_{2b}	Metastasis in multiple ipsilateral lymph nodes, none >6 cm in greatest dimension and ENE(–)
N_{2c}	Metastasis in bilateral or contralateral lymph nodes, none >6 cm in greatest dimension and ENE(–)
N_3	Metastasis in lymph node, >6 cm in greatest dimension and ENE(–); *or* in a single ipsilateral node >3 cm in greatest dimension and ENE(+), *or* multiple ipsilateral, contralateral, or bilateral nodes, any with ENE(+)
N_{3a}	Metastasis in a lymph node >6 cm in greatest dimension and ENE(–)
N_{3b}	Metastasis in a single ipsilateral node >3 cm in greatest dimension and ENE(+), *or* multiple ipsilateral, contralateral, or bilateral nodes, any with ENE(+)

NOTE: A designation of *U* or *L* may be used for any N category to indicate metastasis above the lower border of the cricoid *(U)* or below the lower border of the cricoid *(L)*.

Similarly, clinical and pathologic ENE should be recorded as ENE(–) or ENE(+).

M: Metastasis

M_0	No distant metastasis
M_1	Present distant metastasis

Staging for Cutaneous Squamous Cell Carcinoma

Stage 0	T_{is}	N_0	M_0
Stage I	T_1	N_0	M_0
Stage II	T_2	N_0	M_0
Stage III	T_3	N_0	M_0
Stage III	T_1	N_1	M_0
Stage III	T_2	N_1	M_0
Stage III	T_3	N_1	M_0
Stage IV	T_1	N_2	M_0
Stage IV	T_2	N_2	M_0
Stage IV	T_3	N_2	M_0
Stage IV	Any T	N_3	M_0
Stage IV	T_4	Any N	M_0
Stage IV	Any T	Any N	M_1

ENE, Extranodal extension.

From American Joint Committee on Cancer staging manual, ed 8, 2017.

remove involved or potentially involved lymph nodes as clinically indicated.
2. Radiation: Allows for easier access to poorly exposed tumors such as those of the larynx, oropharynx, nasopharynx, or hypopharynx. Disadvantages include lengthy, time-intensive treatment course, xerostomia, pain, and higher surgical morbidity if salvage surgery is needed.
3. Chemotherapy: Useful only as an adjuvant to radiation therapy or for palliation. Single-agent cisplatin therapy is widely accepted in the U.S. as a standard for chemoradiation regimens for head and neck cancers of any site. Major toxicities include nausea, vomiting, renal toxicity, ototoxicity, and myelosuppression.
4. Reconstruction: Performed with the goal of optimizing functional and cosmetic outcomes. Options include primary closure, local flaps, regional flaps, skin grafts, and microvascular free flaps from other parts of the body (e.g., radial forearm, fibula, anterolateral thigh, latissimus, etc.).

ACUTE GENERAL Rx

- Early-stage disease (Stage I or II):
  1. Single-modality treatment with surgery or radiation alone may be appropriate for early-stage head and neck cancer. The choice between one or the other depends on the specific subsite of the head and neck that is involved and the side effects profile for each modality.
  2. Treatment of the potentially involved lymph nodes in the neck with either neck dissection or radiation is controversial and depends on the clinical scenario and the judgment of the treatment team.
- Locoregionally advanced disease (Stage III or IV):
  1. In general, these patients have large tumors >4 cm and/or cervical nodal metastases. Treatment typically involves multimodality therapy with either surgery followed by radiation therapy or upfront chemoradiation alone. Depending on the presence of certain adverse pathologic features of the surgical specimen, adjuvant chemoradiation may be necessary. If chemoradiation is the initial treatment modality, surgery may be needed in the adjuvant setting for residual or recurrent disease.
  2. Laryngeal cancers are the exception where select advanced disease with T_3 or N_1 tumors can be managed with single-modality therapy with surgery or radiation alone.
  3. Nasopharyngeal cancer is also an exception. This is not a surgical disease. Managed primarily by radiation to primary site and neck for early-stage disease. Chemoradiation is primary treatment for advanced disease. Surgery is reserved for recurrent or residual disease of primary site or neck following radiation therapy.
- Metastatic disease (Stage IVC):
  1. Palliation of symptoms is the primary goal of treatment.
- All patients should be counseled on smoking cessation and avoidance of alcohol.

DISPOSITION

- Prognosis depends on the specific subsite of the head and neck that is involved. Overall 5-yr survival rate for head and neck squamous cell carcinoma is about 55%. This varies with 5-yr survival rates for carcinoma of the lip as high as 89.7% and carcinomas of the hypopharynx as low as approximately 30%.
- Patients are followed on a regular basis multiple times a yr by a head and neck cancer specialist. After a 5-yr disease-free survival, patients are followed on a yearly basis.

REFERRAL

Referral should be made to an otolaryngologist or oral surgeon who specializes in head and neck cancer.

PEARLS & CONSIDERATIONS

PREVENTION

- Encourage all patients to cease using tobacco and to limit alcohol consumption.
- Examine the oral cavity and palpate the neck during the annual physical examination. Work up any suspicious masses or lesions.

Health Care–Associated Infections (HAIs)

BASIC INFORMATION

DEFINITION

Health care–associated infections (HAIs) are infections associated with health care, generally occurring on or after the third calendar day of admission to a hospital. Surveillance classification criteria are established by the Centers for Disease Control and Prevention's (CDC) National Healthcare Safety Network (NHSN). The definitions related to vascular catheter–related infections are summarized in Table E1.

SYNONYMS

Hospital-acquired condition (HAC)–CMS defines certain HAIs as HACs
Nosocomial infections
Hospital acquired infections

ICD-10CM CODES

A04.71	Enterocolitis due to *Clostridium difficile,* recurrent
A04.72	Enterocolitis due to *Clostridium difficile*, not specified as recurrent
B95.62	Methicillin-resistant *Staphylococcus aureus* infection as the cause of diseases classified elsewhere
J15.212	Pneumonia due to methicillin-resistant *Staphylococcus aureus*
A41.02	Sepsis due to methicillin-resistant *Staphylococcus aureus*
K68.11	Postprocedural retroperitoneal abscess
T81.41XA	Infection following a procedure, superficial incisional surgical site, initial encounter
T81.42XA	Infection following a procedure, deep incisional surgical site, initial encounter
T81.43XD	Infection following a procedure, organ and space surgical site, initial encounter
T80.219A	Unspecified infection due to central venous catheter, initial encounter
J95.851	Ventilator-associated pneumonia
T83.091A	Other mechanical complication of indwelling urethral catheter, initial encounter
T88.0XXA	Infection following immunization, initial encounter
T80.29XA	Infection following other infusion, transfusion and therapeutic injection, initial encounter
T80.211A	Bloodstream infection due to central venous catheter, initial encounter
T83.098A	Other mechanical complication of other urinary catheter, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Develop in at least 4% of hospitalized patients; over 1.7 million patients previously estimated.
- In 2011:
  1. HAIs accounted for more than 75,000 deaths.
  2. HAIs in the U.S. cost between $28 and $33 billion annually.
- At least one third of hospital-acquired infections are preventable.
- Leads to increased morbidity and mortality.
- Progress is tracked nationally to reduce HAIs.

PREVALENCE (IN U.S.): Estimated 648,000 patients with at least one HAI/yr in 2011

PREDOMINANT SEX:

- Overall, approximately equal
- Elderly women: Predominantly nosocomial urinary tract infections

PREDOMINANT AGE: Newborns and elderly patients (>60 yr) at highest risk

PEAK INCIDENCE: Varies widely with infection site

RISK FACTORS: Patients with the following conditions can develop HAIs at any age:

- In ICU
- Intubation
- Chronic lung disease
- Renal disease
- Comatose
- Chronic urethral or vascular catheterization
- Malnutrition
- Postoperative state
- Diabetes

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Vary with specific HAIs

ETIOLOGY

- Bacteria (gram-negative bacteria are responsible for >30% of HAIs)
- Fungi
- Viruses

SOURCES AND MODES OF TRANSMISSION:

- Patient's own flora
  1. Comprises resistant organisms associated with hospitalization
  2. Frequently maintained thereafter by persistent GI colonization
- Unwashed hands of staff
  1. Physicians
  2. Nurses
- Invasion of protective defenses (intact skin, respiratory cilia, urinary sphincters, and mucosa)
  1. IV lines/central lines
  2. Catheters
  3. Respiratory equipment
  4. Surgical wounds
  5. Scopes and other imaging devices. CP-CRE outbreaks occurred in recent yrs from difficult-to-clean duodenoscopes
- Failure to provide adequate negative pressure, high-volume air flow chambers for airborne infection isolation of patients with TB or disseminated herpes zoster or chickenpox
- Failure to rapidly identify and provide appropriate care (with isolation or precautions) for patients with communicable diseases
- Food
- Fomites
- Personnel attire can become contaminated. Although studies have not yet verified the link

TABLE E1 Definitions

	Definition	Comments
Catheter tip colonization	Positive culture of the catheter tip that grew to ≥15 cfu/ml (semi-quantitative), 10^2 cfu/ml (quantitative sonication), or 10^3 cfu/ml quantitative vortexing	Qualitative culture should no longer be used
Exit-site infection	Tenderness, erythema of site induration >2 cm	Positive culture of exudate confirms the exit-site infection microbiologically
Catheter-related bloodstream infection (CR-BSI)	One positive blood culture obtained from a peripheral vein and clinical manifestation of infection and (1) catheter tip colonization or (2) a differential time to positivity of more than 120 min and no obvious source of bacteremia except the catheter	Simultaneous quantitative culture from a peripheral vein and the catheter of 5:1 ratio is rarely used. NB: Exclusion of other sources of infection reveals important variability in the final classification in ICU patients. Purulence of the catheter exit site strongly implicates the catheter as the source of infection
Central line–associated bloodstream infection (CLA-BSI)	One positive blood culture and clinical manifestation of infection in a patient with a catheter in place with no other source of bacteremia except the catheter	Easy-to-collect definitions for epidemiologic purposes. Exposed to an overestimation of the BSI due to catheter infection, especially in ICU and oncohematologic patients
Catheter-related clinical sepsis	Clinical manifestation of infection that disappears within 48 h of catheter removal and a positive catheter tip culture and no other obvious treated source of infection	Represent 30%-50% of catheter-related infections with general manifestations. Not easy to collect routinely but may need antimicrobial treatment (see text)

BSI, Bloodstream infection; *ICU,* intensive care unit.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

between attire contamination and disease transmission, cross-contamination of previously washed hands can occur
- Inattention to safe injection practices has led to outbreaks of hepatitis and fungal meningitis
  1. Do not administer medications from a syringe to multiple patients even if the needle is changed.
  2. Use fluid infusion and administration sets (e.g., IV bags or bottles, tubing, connectors) for one patient only and dispose after each use. Do not use bags or bottles as a common source of supply for multiple patients.
  3. Use single-dose vials for parenteral medications whenever possible and do not administer medications from single-dose vials to multiple patients or combine leftover contents for later use.
  4. Single-dose, single-use vials do not have preservative and should be used for a single patient and a single case, procedure, and injection.
  5. When a single dose or single vial is accessed or opened, discard as per manufacturer or at the end of the case or procedure (whichever comes first).
  6. Insulin pens should be used for one single designated person only even if the needle is changed.

RISKS AMPLIFIED:
- Use of broad-spectrum antibiotics
  1. Select highly resistant bacteria.
  2. Establish multidrug-resistant bacteria as endemic flora in microenvironments within the hospital.
  3. Consider antibiotic stewardship programs to reduce these risks.
- May be required by accrediting agency or government
- Highly vulnerable patients with specific risk factors
  1. Immunosuppression (as a result of therapy, transplantation, AIDS)
  2. Old age
  3. Postsurgery
  4. Prolonged surgery
  5. Chronic lung disease
  6. Ventilator dependence
  7. Antacid therapy
  8. Vascular lines
  9. Hyperalimentation
  10. ICU stay
  11. Recent antibiotic therapy
- Clustering of seriously ill patients
  1. Often with wounds or contaminated drainage
  2. Intensifying probability of cross-infection

PREVENTION STRATEGIES: Handwashing and hand hygiene between all patient contacts is the single most important method of decreasing HAI:
- Regular soap and water for at least 15 sec.
- Chlorhexidine (particularly good for gram-positive organisms such as methicillin-resistant *Staphylococcus aureus* [MRSA]), alcohol hand rub, or other antiseptic for resistant organisms.
- Purpose of soap and water handwashing:
  1. Degrease hand surfaces.
  2. Flush away oils and associated bacteria, removal of visible dirt or body fluids.
- Procedure:
  1. Lukewarm water
  2. Must include all surfaces
  3. Special attention to areas between fingers and to the dirtier dominant hand (most people reflexively wash the cleaner, nondominant hand more vigorously)
- Alcohol hand sanitizers:
  1. Improve handwashing frequency (less drying to hands, faster, and no need for wash basin and towels for drying)
  2. Significantly reduce HAIs
  3. Now recommended in essentially all routine health care settings
  4. Rub hands until dry, approximately 15 sec
- Environmental cleaning:
  1. New supplemental no-touch technologies such as hydrogen peroxide vapor or mist or ultraviolet irradiation appear to reduce environmental contamination from *Clostridium difficile* spores, *Norovirus*, and resistant microorganisms.
  2. Clinical equipment should be properly disinfected or sterilized per manufacturer's instructions.
  3. High-touch items in patient environment should undergo frequent, thorough disinfection.
  4. Follow manufacturer written instructions for required contact time with disinfectant.

METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS:
- MRSA bacteremia decreased 13% between 2011 and 2014 in the U.S.
- Health care–associated MRSA strains are typically resistant to many antibiotics, remaining susceptible to vancomycin and trimethoprim–sulfamethoxazole.
- High-risk factors include dialysis, recent stay in acute or long-term care facilities.
- Control measures include hand hygiene, disinfection of equipment, protective attire for isolation, and standard precautions.
- Community-acquired MRSA (CA-MRSA) is associated with soft tissue, presenting as boils, rash, or so-called spider bite, and typically occurs in patients who have no recent health care or hospital interaction.
- CA-MRSA often not found in nares.
- CA-MRSA can be sensitive to fluoroquinolones, clindamycin, and/or erythromycin in addition to vancomycin and trimethoprim/sulfamethoxazole.

Refer to the topic "Methicillin-Resistant *Staphylococcus aureus*" for more information.

VANCOMYCIN-RESISTANT ENTEROCOCCUS FAECIUM (VREF):
- The percentage of HAIs caused by VREF increased more than twentyfold between 1989 and 1993, rising from 0% to 9%. By 2005, VREF, vancomycin-resistant *E. faecalis,* and other vancomycin-resistant species of enterococci had become common and endemic nosocomial pathogens accounting for 15% to 40% of all enterococci isolated in the hospital setting.
- A high percentage of VREF isolated, 80%, are also ampicillin resistant.
- Factors predisposing to VREF colonization or infection include a high percentage of hospital days receiving antibiotic therapy, use of IV, underlying disease, immunosuppression, and abdominal surgery.
- Evidence suggests that the vehicle is the hands of health care workers (HCWs).
- Control measures:
  1. Aggressive isolation of colonized or infected patients.
  2. Restraint in using broad-spectrum antibiotics.
  3. Compliance with hand-hygiene best practices.

Refer to the topic "Vancomycin-Resistant Enterococcus" for more information.

CLOSTRIDIUM DIFFICILE:
- Causes diarrhea as a result of pseudomembranous colitis.
- Accounts for 15% to 25% of health care–associated diarrhea. Recent survey found *C. difficile* was the third most common HAI and accounted for 70% of gastrointestinal HAIs.
- Warrants contact precautions and disinfection against spores, for example, properly diluted bleach, supplemental no-touch technology (silver, hydrogen peroxide vapor or mist, ultraviolet light, hypochlorous acid).
- Alcohol hand sanitizer likely does not eliminate spores of this organism: Can use soap and water to wash hands at sink.
- Spores can be dispersed in the air or room environment surrounding patients.
- Treatment is tiered based on severity. Vancomycin or fidaxomicin is recommended to treat initial onset.
- Rising incidence of *C. difficile* infection with emerging strains that have up to twenty-threefold more toxin production.
- Toxin assays vary widely in ability to detect toxin.
- Only unformed stool specimens should be submitted for laboratory *C. difficile* testing.
- Polymerase chain reaction (PCR) and nucleic acid amplification test/loop mediated isothermal DNA amplification (NAAT/LAMP) are more sensitive test methods than enzyme immunoassay (EIA).
- Antibiotics can predispose persons by altering their normal gut flora.
- Can present in healthy patients with no known risk factors.
- Sometimes causes toxic megacolon or fulminant colitis.

NOROVIRUS:
- Patients present with sudden onset of nausea, vomiting, and/or diarrhea
- Now considered yr round rather than seasonal
- Disinfection with bleach or agent with efficacy against norovirus.
- Often need to isolate exposed persons for average incubation period, such as 3 days, to prevent outbreak

SURVEILLANCE
- Crucial for early identification of infections. Enables:
  1. Immediate intervention
  2. Education
- Prospective, concurrent, hospital surveillance:
  1. Electronic data mining provides accurate review

2. Feasible with sophisticated computerized data collection and analysis
- Targeted surveillance addresses high-risk procedures and patient populations.
  1. May be mandated by state or federal government
- Routine rate calculations and statistical analyses:
  1. Use device-specific days, procedure-specific cases, or patient-days as denominators.
  2. Enhance early recognition of infections by body site and by organism.
  3. Facilitate proper early control of potential outbreaks.
- Active surveillance or screening cultures for multidrug-resistant organisms (MDROs); for example, high-risk populations for MRSA

Dx DIAGNOSIS

MOST COMMON HEALTH CARE–ASSOCIATED INFECTIONS:
- Device-associated infections (26%) (central line–associated bloodstream infections, catheter-associated urinary tract infections, and ventilator-associated pneumonias)
- Surgical site and other soft tissue infections (22%)
- Pneumonia (22%)
- GI infections (17%)

HEALTH CARE–ASSOCIATED UTIS:
- General associations:
  1. Indwelling urinary (e.g., Foley) catheters
  2. Inappropriate catheter care (including opening catheter junctions)
  3. Female sex
  4. Absence of systemic antibiotics
- Physical findings:
  1. Fever
  2. Dysuria
  3. Leukocytosis
  4. Pyuria
  5. Flank or costovertebral angle tenderness
- Usual organisms:
  1. *E. coli*
  2. *Candida* spp.
  3. *Enterococcus* spp.
  4. *Pseudomonas* spp.
  5. *Klebsiella* spp.
  6. *Enterobacter* spp.
- Sepsis in 1% to 3% of hospital-associated UTIs
- Prevention bundle to eliminate catheter-associated UTIs (CAUTIs):
  1. Use meticulous aseptic technique during insertion and daily perineal care.
  2. Avoid unnecessary urinary catheters; remove promptly.
  3. Never open the catheter-collection tubing junction (keep system closed).
  4. Obtain all specimens using sterile syringe.
  5. Secure the Foley.
  6. Remove Foley catheters as soon as possible.
  7. Substitute intermittent catheterization for Foley catheters.

HEALTH CARE–ASSOCIATED BLOODSTREAM INFECTIONS:
- General associations:
  1. IV lines
  2. Arterial lines
  3. Central venous pressure (CVP) lines: Lead to catheter-associated bloodstream infection (CLABSI)
  4. Phlebitis
  5. Hyperalimentation
  6. Lack of safe injection best practices
- Fever possibly only presenting sign
- Exit site of all vascular lines carefully evaluated for:
  1. Erythema
  2. Induration
  3. Tenderness
  4. Purulent drainage
- Usual organisms for device-associated bacteremia:
  1. *S. aureus* (including MRSA)
  2. *Staphylococcus epidermidis* for long-term IV lines
  3. *Enterobacter* spp.
  4. *Klebsiella* spp.
  5. *Candida* spp.
  6. *Pseudomonas aeruginosa* may come from a water source or reflect cutaneous bacteria
- Phlebitis in 1.3 million patients yearly
- Approximately 10,000 annual deaths from IV sepsis
- Prevention bundle to eliminate central line-associated bloodstream infections (CLABSIs):
  1. Meticulous sterile technique during central catheter line insertion.
  2. Emphasis should be placed on attention to detail, including handwashing, adherence to guidelines for catheter insertion and maintenance, appropriate use of antiseptic solutions such as chlorhexidine (CHG) to prepare the skin before central line insertion.
  3. Modified catheter, for example, antiseptic-coated line, may reduce risk for endoluminal colonization and catheter-related sepsis in subclavian lines.
  4. Decrease use of routine IVs and encourage PO intake.
  5. Avoid using a femoral vein insertion site. Subclavian central line site is associated with lower infection rate than jugular.
  6. Bundle to prevent CLABSIs includes hand hygiene, CHG skin prep for insertion of central lines, full barrier protection for insertion of central lines, removal of unnecessary lines, insertion checklist.
  7. Consider daily CHG baths in ICUs.
  8. In the U.S., 50% decrease in CLABSI between 2014 and 2018.
  9. Table E2 summarizes recommended strategies for prevention of catheter-related bloodstream infections (CR-BSI) in ICU patients.

TABLE E2 Main Recommended Strategies for Prevention of CR-BSI in ICU

Structure and Process of Care
Adequate nurse-to-patient ratio
Use only trained personnel who demonstrate competence for catheter insertion and maintenance
Educate, assess knowledge, and audit adherence to guidelines of ICU HCWs
Conduct a continuous quality-improvement program based on recommendations and adapted locally
Organize a follow-up of the institution's process of care and CR-BSI rate
Participate in a surveillance network
Catheter Insertion
Hand hygiene
Full barrier precautions for CVC insertion
Preparation of cutaneous site with chlorhexidine
Subclavian rather than jugular or femoral access (should be weighed against the risk of mechanical complications)
Avoid subclavian access for dialysis catheters
Subcutaneous tunneling for internal jugular or femoral short-term CVCs
Ultrasound guidance to reduce number of cannulation attempts and mechanical complications for jugular and femoral access
Use a sterile sleeve for all pulmonary artery catheters
Do not routinely replace CVCs (even using guidewire exchange procedure)
Chlorhexidine-sulfadiazine impregnated for short-term CVCs only if the level of CR-BSI is high despite implementation of a comprehensive strategy to reduce the rate of CR-BSI
Catheter Maintenance
Immediate dressing change if loosened, soiled, or moistened
Remove catheters as soon as possible after intended use
Daily visual inspection of the catheter site
Sterile transparent or gauze dressings for CVCs
Gauze when blood is oozing from the insertion site
Chlorhexidine-impregnated gels or chlorhexidine sponge dressings should be used to reduce CR-BSI from arterial catheters and CVCs
Replace tubing used to administer blood products and lipid emulsions (including propofol) within 24 hours of initiating the infusion
Replace administration sets no more frequently than at 4-day intervals, but at least every 7 days

CR-BSI, Catheter-related bloodstream infection; *CVC,* central venous catheter; *ICU,* intensive care unit; *HCW,* health care worker.
From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

HEALTH CARE–ASSOCIATED PNEUMONIAS:
- More common in ICUs
- General associations:
  1. Aspiration
  2. Intubation: Leads to ventilator-associated events (VAE) or ventilator-associated pneumonia (VAP)
  3. Altered consciousness
  4. Old age
  5. Chronic lung disease
  6. Postsurgery
  7. Antacids
  8. Head of bed not elevated
- Signs of pneumonia common among patients on general wards:
  1. Cough
  2. Sputum
  3. Fever
  4. Leukocytosis
  5. New infiltrate on chest x-ray examination
- Signs more subtle in ICUs because many patients have purulent sputum because of chronic intubation:
  1. Change in sputum character or volume
  2. Small changes on chest x-ray examination
- Usual organisms:
  1. *S. aureus* (including MRSA)
  2. *Pseudomonas aeruginosa*
  3. *Enterobacter* spp.
  4. *Acinetobacter* spp.
  5. *Klebsiella* spp.
- Less common organisms:
  1. *Stenotrophomonas* spp.
  2. *Legionella* spp., *Flavobacterium* spp.
  3. Respiratory syncytial virus (infants)
  4. Adenovirus
- 1% of hospitalized patients affected
- Mortality rate high (40%)
- Prevention bundle:
  1. Use meticulous sterile technique during suctioning and handling airway.
  2. Do not routinely change ventilator breathing circuits and components. For heat and moisture exchangers, no more frequently than every 48 hr.
  3. Drain respirator tubing without allowing fluid to return to respirator.
  4. Wash hands routinely to prevent colonization of patients and transfer of organisms among patients.
  5. Use of a bundle to prevent VAEs and VAPs to include elevate the head of bed, provide deep vein thrombosis (DVT) prophylaxis, provide peptic ulcer disease (PUD) prophylaxis, hold sedation, test for ability to extubate, control glucose, gastric decontamination.
  6. Consider oral mouth care with CHG for vented patients in ICUs.

SURGICAL AND HEALTH CARE–ASSOCIATED SOFT TISSUE INFECTIONS:
- Associations:
  1. Decubitus ulcers
  2. Surgical site risks: Contaminated or dirty or infected, the American Society of Anesthesiologists' (ASA) physical status classification of ASA 3 or 4, duration of surgery over national average, usually 3 hr
  3. Abdominal surgery
  4. Presence of drain
  5. Preoperative length of stay
  6. Surgeon
  7. Presence of other infection
- Physical findings:
  1. Decubitus ulcer with fluctuance at margin or under firm eschar
  2. Erythema extending >2 cm beyond margin of surgical wound
  3. Tenderness
  4. Induration
  5. Erythema
  6. Fluctuance
  7. Purulent drainage
  8. Dehiscence of sutures
- Usual organisms:
  1. *S. aureus* (including MRSA)
  2. *Enterococcus* spp.
  3. *Enterobacter* spp.
  4. *Acinetobacter* spp.
  5. *E. coli* spp.
- Prevention:
  1. Use careful skin care and frequent, proper positioning of patient to prevent decubitus ulcer.
  2. Use meticulous sterile surgical technique.
  3. Use properly washed and sterilized instruments, processed in accordance with manufacturer's instructions. Minimize immediate-use steam sterilization (formerly known as flash sterilization).
  4. Wash hands to decrease colonization when handling postoperative wound.
  5. Limit prophylactic antibiotics to 24 hr perioperatively.
  6. Double wrap contaminated dressings (hold in gloved hand and evert gloves over dressings) before disposal.
  7. Surgical Care Improvement Project (SCIP) bundle to include antibiotic prophylaxis selection, receipt of antibiotic within 1 hr before surgery, discontinuation of antibiotic within 24 hr of surgery end time, cardiac surgery patients with controlled 6 A.M. postoperative blood glucose, clip rather than shave prep, postoperative normothermia for colorectal surgery patients, removal of Foley catheter by end of postoperative day 2 (except for urologic, gynecologic, or perineal procedures, or on paralytics, vasopressors/inotropics during ICU stay).
  8. Preadmission nares MRSA screening often beneficial for open heart and orthopedic implants when time is allowed for decolonization, chlorhexidine showers, and appropriate antibiotic prophylaxis selection.
  9. Often, preadmission nares MRSA screening is also performed.
  10. Consider antiseptic shower the night before and the morning of surgery.

LABORATORY TESTS
- Appropriate to specific HAI and specific patient's condition
- Cultures generally indicated for proper confirmation of responsible pathogens:
  1. Urine
  2. Blood
  3. Sputum
  4. Soft tissue
- Molecular analysis of health care–associated epidemics:
  1. Plasmid fingerprinting
  2. Restriction endonuclease digestion (plasmid and genomic DNA)
  3. Peptide analysis
  4. Immunoblotting
  5. Ribosomal RNA (rRNA) typing
  6. DNA probes
  7. Multilocus enzyme electrophoresis
  8. Restriction fragment length polymorphism (RFLP)
  9. PCR
  10. Provide confirmation of point-source or common strains and corroboration of hypotheses reached using classic epidemiology

IMAGING STUDIES
Rarely needed for diagnosis of HAI; helpful for deep surgical site infection

Rx TREATMENT

ACUTE GENERAL Rx
- Appropriate to etiologic organism:
  1. Antibiotic
  2. Antifungal
  3. Antiviral
- Specific therapy determined after careful consideration of resident flora within the microenvironment in which the patient was hospitalized.
  1. Empiric therapy.
  2. Frequently difficult to fashion accurately.
  3. Often undesirable unless the patient's clinical condition requires urgent treatment.
- Consultation for expert advice regarding antibiotic selection in view of known epidemiologic risks within the hospital (hospital epidemiologist or infectious disease specialist).
- Avoid unnecessary treatment for organisms that are colonizing (no signs or symptoms of infection) but not infecting patients.
- Prevention of spread of communicable diseases.
  1. Isolation or precautions (airborne, droplet, contact isolation precautions, and combinations thereof).
  2. Classic schema (strict, respiratory isolation and contact [skin and wound] precautions) have been replaced by more streamlined revised guidelines (airborne, droplet, contact isolation precautions, and combinations thereof).
  3. Less careful response to some diseases (e.g., hemorrhagic fevers) inadvertently induced by removal of strict isolation category.
  4. Universal or standard precautions to protect HCWs against splash or splatter of blood or body fluids.
  5. Tracking roommates of patients with communicable disease, such as norovirus

or influenza, and using precautions during the incubation period.

- Universal or standard precautions used for all patients during all anticipated contacts with blood, body fluids, or secretions.
  1. Gloves.
  2. Goggles or eye shield.
  3. Gowns that prevent blood or potentially infectious materials from passing through.
- Consider aggressive isolation to restrict spread of multidrug-resistant organisms and their plasmids.
  1. MRSA.
  2. VREF.
  3. MDR-GNRs (multidrug-resistant gram-negative rods) can include extended-spectrum β-lactamases (ESBL), carbapenem-resistant Enterobacteriaceae (CP-CRE), and some *Acinetobacter baumannii.* New microbiology interpretive criteria (breakpoints) can result in no longer reporting mechanism of resistance.
  4. New Delhi metallo-β-lactamase 1 (NDM-1): These are gram-negative Enterobacteriaceae with a new type of carbapenem-resistance gene.
  5. Colistin-resistant *E. coli.* The *mcr-1* gene that makes bacteria resistant to colistin was found twice in the U.S. Most recently, an *mcr-9* gene was also found in a patient in the U.S. This resistance could move to other bacteria. Colistin is a last-resort antibiotic for treating patients with infection from multidrug-resistant organisms.
  6. VIM- and IMP-type metallo-ß-lactamase producers.

Refer to the topic "Multidrug-Resistant Gram Negative Rods" for more information.

DISPOSITION

The infection prevention and control service or hospital epidemiologist should be notified when infectious complications occur in the hospital setting; most, but not all, HAIs are potentially avoidable, and every effort should be taken to minimize the risk of infections associated with health care. Nationwide success in achieving and sustaining zero CLABSIs, zero CAUTIs, and zero VAPs warrants widespread use of infection prevention bundles to target zero HAIs.

REFERRAL

- To infection preventionist
- To hospital epidemiologist

PEARLS & CONSIDERATIONS

COMMENTS

- Sharp and splash injuries to staff are relatively rare, but nearly all are preventable.
  1. Nurses incur most injuries.
  2. Usual causes:
     a. Needle sticks
     b. Scalpel and surgical needle injuries
     c. Blood splashes
  3. Prevention:
     a. Never recap needles.
     b. Dispose of needles only in rigid, impermeable plastic containers.
     c. Clearly announce instrument passes in the operating room and during procedures. Use passing trays.
     d. Use needleless systems for vascular access and neutral displacement central line connectors.
     e. Use gloves, mask, and goggles/eye shield if aerosol or splash is likely.
     f. Never leave needles or other sharp items in beds.
     g. Never dispose of sharp items in regular trash bags.
  4. Infection prevention and control or employee health staff should be consulted immediately after exposure to determine need for prophylaxis for hepatitis B or HIV.
  5. All clinical staff should be immune to hepatitis B (natural or vaccine).
- Fungi previously considered to be contaminants are now risks for patients with cancer and organ transplantation.
  1. *Candida* spp.
     a. *C. auris*
     b. *C. guilliermondii*
     c. *C. krusei*
     d. *C. parapsilosis*
     e. *C. tropicalis*
     f. Note that *Candida auris* has emerged with resistance, sometimes to all three major classes of antifungal drugs. The fungus has spread quickly, causing outbreaks and resulting in invasive infection with higher risk of death. These multidrug-resistant isolates are often misidentified by automated lab systems. Contact precautions in a private room are recommended, with attention to thorough daily and terminal environmental disinfection. Current recommendation is for a disinfectant effective against spores.
  2. *Aspergillus* spp.
  3. *Curvularia* spp.
  4. *Bipolaris* spp.
  5. *Exserohilum* spp.
  6. *Alternaria* spp.
  7. *Fusarium* spp.
  8. *Scopulariopsis* spp.
  9. *Pseudallescheria boydii*
  10. *Trichosporon beigelii*
  11. *Malassezia furfur*
  12. *Hansenula* spp.
  13. *Microsporum canis*
- Focused, committed efforts by the entire health care staff continuously directed toward prevention:
  1. Each HAI addressed as an opportunity to improve the delivery of safe patient care always using best practices
  2. Essential for individual staff members to understand that small risks applied to large populations result in a large number of total events (i.e., HAIs)
- Antibiotic stewardship:
  1. Choose appropriate antibiotic.
  2. Minimize vancomycin use.
  3. Consider procalcitonin to guide antibiotic use for sepsis.
  4. Follow CDC core elements and checklist.
- The Centers for Medicare & Medicaid Services denies inpatient payments for certain HAIs. Total reimbursement is linked to performance by comparing HAI outcome with national benchmark, top percentile, and achieved standardized infection ratios (SIR).
  1. The number of surgical-site *S. aureus* infections acquired in the hospital, particularly cardiac or orthopedic, has been reduced by rapid screening and decolonizing of nasal carriers of *S. aureus* before surgery.
  2. Universal decolonization of ICU patients for MRSA has been advocated without nares screening as a model to reduce bloodstream infection and MRSA clinical isolates.

Heart Block, Complete (PTG)

BASIC INFORMATION

DEFINITION

Complete heart block (CHB) is the absence of electrical impulse transmission from the atria to the ventricles when atrioventricular (AV) junction is not physiologically refractory, due to a functional or anatomical impairment of the conduction system, resulting in a bradycardia characterized by AV dissociation. It may be acquired or congenital. CHB can be permanent or reversible.

SYNONYMS

Third-degree AV block
CHB
Complete AV block

ICD-10CM CODE
I44.2 Atrioventricular block, complete

EPIDEMIOLOGY & DEMOGRAPHICS

- The prevalence of CHB is 0.04%.
- The prevalence of CHB increases with age.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical examination may be normal. Cannon A waves may appear in the jugular vein periodically due to the right atrium contracting during ventricular systole. Patients may present with the following clinical manifestations:

- Dizziness, palpitations
- Syncope or presyncope (due to reduced cardiac output)
- Fatigue, impaired exercise tolerance
- Mental status changes
- Congestive heart failure
- Angina pectoris
- Some patients may be asymptomatic (e.g., congenital CHB)

ETIOLOGY

- Fibrosis or sclerosis of the conduction system, Lenegre and Lev disease
- Acute myocardial infarction—inferior (14%) or anterior (2%) wall of patients, usually within 24 hours
- Drug effect (digitalis, calcium channel blockers, beta-blockers, amiodarone)
- Cardiomyopathy and myocarditis
- Infiltrative processes of the myocardium (amyloidosis, sarcoidosis, scleroderma, tumor)
- Metabolic abnormalities (hyperkalemia, hypoxia, hypothyroidism)
- Lyme carditis, rheumatoid nodules, polymyositis, Chagas disease
- Neuromuscular disorders (Becker muscular dystrophy, myotonic muscular dystrophy)
- Congenital (birth from mothers with systemic lupus)
- Hyperkalemia
- Familial: SCN5 sodium channel mutations have been associated with CHB
- Iatrogenic (cardiac surgery, catheter ablation of arrhythmias, percutaneous coronary intervention). Transcatheter aortic valve implantation (TAVI) is shown to be frequently associated with new conduction abnormalities; patients with preexisting right bundle branch block are at increased risk of CHB (resolves over time in most patients).
- Paroxysmal due to phase 4 block of the His-Purkinje system

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis includes lesser degree of AV block, automatic accelerated junctional rhythms, and nonconducted premature atrial contractions.
- The atrial rate must be faster than the ventricular rate (more As than Vs), and the junctional or ventricular rate is regular. Episodes of AV dissociation with an accelerated ventricular or junctional pacemaker overtaking the sinus node can often look like heart block on a single electrocardiogram.

WORKUP

- Workup such as routine labs, cardiac biomarkers, and cardiac imaging should be dictated by the clinical circumstances.
- ECG: Diagnostic of the disease (Figs. 1 and 2):
  1. P waves are present with a regular atrial rate that is faster than the ventricular rate.
  2. P waves are not related to the QRS complexes. The PR intervals are variable.
  3. RR intervals are regular.
  4. QRS complexes may be narrow with a rate of 40 to 60 beats/min (block proximal to His bundle) or wide with a rate of <40 beats/min (block distal to His bundle), depending on the location of the block in the conduction system.
  5. Complete AV block can result from block at the level of AV node, within the His bundle, or distal to it, in the Purkinje system.

TREATMENT

ACUTE GENERAL Rx

- Initial treatment should focus on the hemodynamic stability and symptoms of the patient.
- Fig. 3 illustrates the evaluation and management of third degree AV block.
- Consider temporary pacemaker insertion if ventricular escape rate is slow (<40 beats/min) and associated with symptoms or hemodynamic compromise as well as wide QRS escape rhythms, which can be unstable, and QT prolongation above 500 ms, increasing the risk of torsade de pointes ventricular tachycardias.
- CHB as a complication of inferior MI usually only requires temporary pacing; however, a CHB as a result of anterior MI often requires permanent pacing (Table 1).
- Acquired CHB usually requires pacing, but patients with congenital CHB often have sufficiently rapid escape rhythm to prevent symptoms and avoid permanent pacemaker implantation.
- Withdraw AV-nodal blocking agents if any.
- Short-term therapy (until adequate pacing therapy is established):
  1. Vagolytic agents such as atropine may be used to increase the rate of the escape rhythm (for AV nodal level blocks).
  2. Catecholamines such as isoproterenol transiently used for a CHB at any site (use with extreme caution or not at all in patients with coronary artery disease or in patients with digitalis toxicity).
  3. Percutaneous external cardiac pacing (uncomfortable for patients and not always reliably capturing the ventricle).
- Drugs cannot be relied on to increase HR for more than several hours or days without side effects; therefore, temporary or permanent pacemaker insertion is indicated.
- Symptomatic CHB in the absence of a condition that is likely to resolve is an ACC/AHA/HRS Class I indication for permanent pacemaker (PPM) placement.
- Class I indications for PPM placement in asymptomatic patients according to the ACC/AHA guidelines include:
  1. Patients in sinus rhythm, with documented asystolic pauses greater than or equal to 3.0 sec or an escape rate <40 beats/min, or with an escape rhythm that is below the AV node
  2. Patients with atrial fibrillation and bradycardia with one or more pauses of at least 5 sec or longer
  3. After catheter ablation of the AV junction
  4. If cardiomegaly or LV dysfunction is present with ventricular rates of 40 beats/min or faster
  5. Postoperative CHB that is not expected to resolve
  6. When it is associated with neuromuscular diseases, such as Erb dystrophy (limb-girdle muscular dystrophy), Kearns-Sayre syndrome, myotonic muscular dystrophy, and peroneal muscular atrophy
  7. CHB present during exercise in the absence of myocardial ischemia
- Therapy is directed toward the underlying etiology if there is a reversible source (i.e., IV antibiotics for Lyme disease).
- Table 2 summarizes the management of complete heart block.

CHRONIC Rx

Dual-chamber pacemaker implantation. Patients with a pacemaker need regular follow-up and pacemaker monitoring to ensure proper device functioning. Interest has developed recently in placing the ventricular pacing lead in the His bundle region, which can result in a narrow-paced QRS and may prevent ventricular dyssynchrony associated with traditional RV pacing.

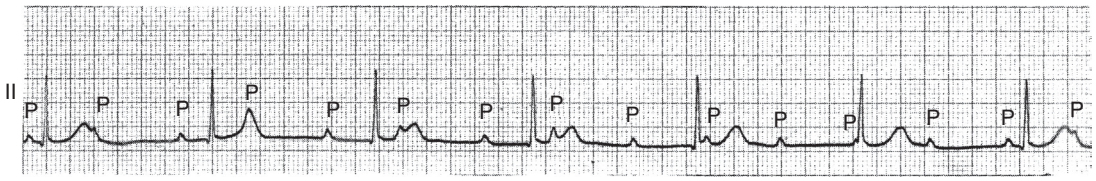

FIG. 1 Third-degree (complete) atrioventricular heart block is characterized by independent atrial (P) and ventricular (QRS) activity. The atrial rate is always faster than the ventricular rate. The PR intervals are completely variable. Some P waves fall on the T wave, distorting its shape. Others may fall in the QRS complex and be "lost." Notice that the QRS complexes are of normal width, indicating that the ventricles are being paced from the atrioventricular junction. (From Goldberger AL, [ed]: *Clinical electrocardiography,* ed 5, St Louis, 1994, Mosby.)

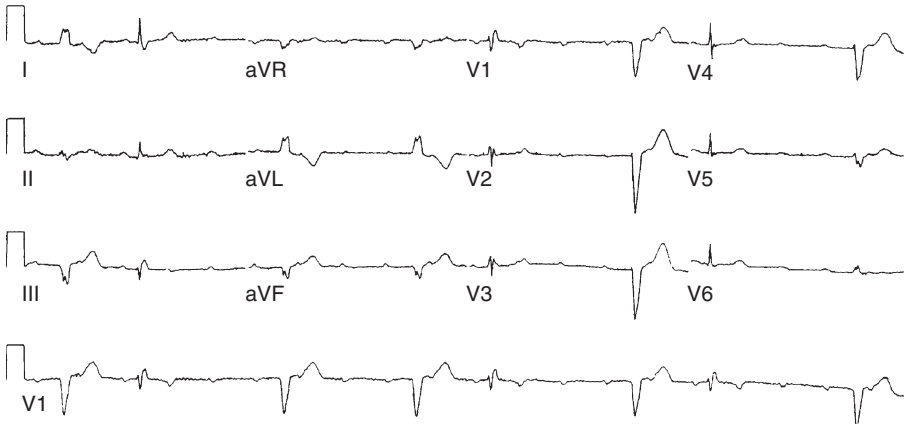

FIG. 2 High-grade atrioventricular block. Note that only three P waves conducted to the ventricle in the whole tracing. Conducted P waves were associated with normal PR intervals and right bundle branch block, a finding suggesting infranodal block. All other P waves were blocked, and ventricular escape rhythm with a left bundle branch block pattern is observed. Note that the block is not caused by retrograde concealment in the atrioventricular node or His-Purkinje system from the ventricular escape complexes because the conducted P waves occurred at a short cycle following the escape complexes. *aVF,* Augmented vector foot; *aVL,* augmented vector left; aVR, augmented vector right. (From Issa Z et al: *Clinical arrhythmology and electrophysiology,* ed 2, Philadelphia, 2012, WB Saunders.)

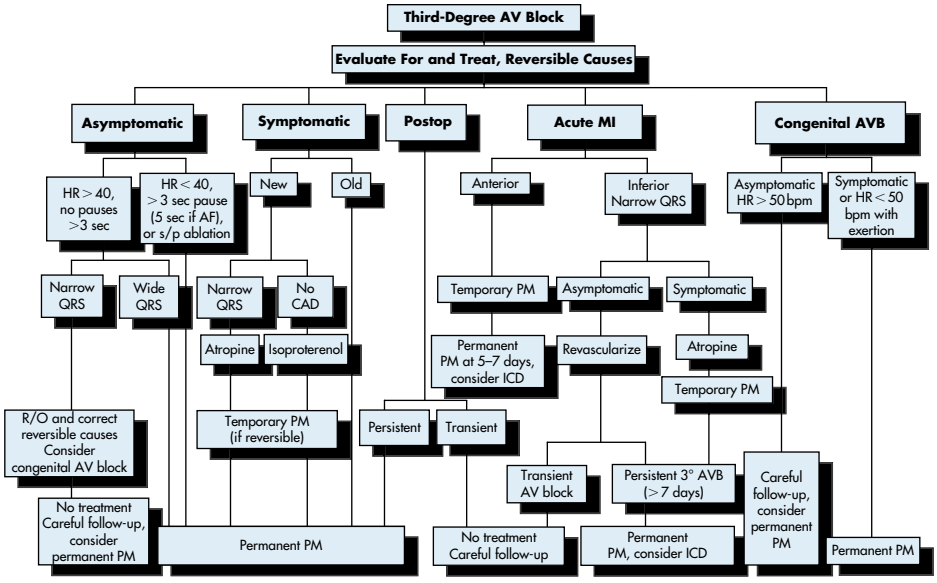

FIG. 3 Evaluation and management of third-degree atrioventricular *(AV)* block. *AF,* Atrial flutter; *AVB*, atrioventricular block; *bpm,* beats per minute; *CAD*, coronary artery disease; *HR,* heart rate; *ICD*, implantable cardioverter defibrillator; *MI*, myocardial infarction; *PM*, pacemaker; *R/O,* rule out; *s/p,* after. (From Olshansky B et al: *Arrhythmia essentials*, ed 2, Philadelphia, 2017, Elsevier.)

TABLE 1 Indications for Pacing in AV Block

Class I

1. Third-degree or advanced second-degree AV block at any anatomic level associated with any one of the following conditions:
   a. Symptoms (including heart failure) attributable to AV block *(Level of Evidence: C)*
   b. Arrhythmias and other medical conditions that require drugs that result in symptomatic bradycardia *(Level of Evidence: C)*
   c. Documented periods of asystole >3.0 seconds, any escape rate <40 beats/min, or any escape rhythm below the AV junction (e.g., a wide QRS morphology) in awake, asymptomatic patients in sinus rhythm *(Level of Evidence: C)*
   d. A documented period of asystole >5 seconds in awake, asymptomatic patients in atrial fibrillation *(Level of Evidence: C)*
   e. After catheter ablation of the AV junction *(Level of Evidence: C)*
   f. Postoperative AV block that is not expected to resolve after cardiac surgery *(Level of Evidence: C)*
   g. Neuromuscular diseases, such as myotonic muscular dystrophy, Kearns–Sayre syndrome, Erb (limb-girdle) dystrophy, and peroneal muscular atrophy, with or without symptoms of bradycardia *(Level of Evidence: B)*
2. Asymptomatic third-degree AV block at any anatomic site with an average awake ventricular rate >40 beats/min in patients with cardiomegaly or left ventricular dysfunction
3. Second-degree or third-degree AV block during exercise in the absence of myocardial ischemia (*Level of Evidence: C*)
4. Symptomatic second-degree AV block regardless of type or site of block (*Level of Evidence: B*)

Class IIa

1. Advanced second-degree or third-degree AV block at any anatomic site with an average ventricular rate >40 beats/min in the absence of cardiomegaly (*Level of Evidence: C*)
2. Asymptomatic second-degree AV block at intra- or infra-His levels found at electrophysiologic study (*Level of Evidence: B*)
3. First-degree or second-degree AV block with symptoms similar to those of pacemaker syndrome (*Level of Evidence: B*)
4. Asymptomatic type II second-degree AV block with a narrow QRS. When type II second-degree AV block occurs with a wide QRS, including isolated right bundle branch block, pacing becomes a Class I recommendation. (*Level of Evidence: B*)

Class IIb

1. AV block due to drug use or toxicity when the block is expected to recur even after withdrawal of the drug (*Level of Evidence: B*)
2. Neuromuscular diseases, such as myotonic muscular dystrophy, Kearns–Sayre syndrome, Erb (limb-girdle) dystrophy, and peroneal muscular atrophy with any degree of AV block (including first-degree AV block), with or without symptoms of bradycardia (*Level of Evidence: B*)

Class III

1. Asymptomatic first-degree AV block (*Level of Evidence: B*)
2. Asymptomatic type I second-degree AV block at a site above the His (i.e., the AV node) level or not known to be intra- or infra-Hisian by electrophysiologic study (*Level of Evidence: B*)
3. AV block expected to resolve and unlikely to recur (e.g., drug toxicity, Lyme disease, nocturnally in sleep apnea, early postoperative status, transient increases in vagal tone) (*Level of Evidence: B*)

AV, Atrioventricular.
From Bonow RO et al: *Braunwald's heart disease: a textbook of cardiovascular medicine,* ed 9, Philadelphia, 2012, WB Saunders.

DISPOSITION

- Mortality is highest in the neonatal period in congenital CHB.
- Prognosis is favorable after insertion of a pacemaker and is related to the underlying etiology of complete AV block (e.g., myocardial infarction, cardiomyopathy).
- Nonrandomized studies have shown that PPM insertion improves survival in patients with CHB.

REFERRAL

All patients with CHB should be referred to a cardiologist for consideration of temporary and/or PPM implantation.

PEARLS & CONSIDERATIONS

COMMENTS

- Patients should be instructed to avoid activities that may damage the pacemaker (e.g., contact sports).
- Pacemaker manufacturers do not recommend any special restrictions regarding proximity to typical household items.
- All pacemaker manufacturers offer pacemakers that are MRI compatible. Older pacemaker models and leads may have a strong relative contraindication for MRI.
- Leadless pacemakers that are implanted directly into the right ventricle using a special delivery system are available for special indications and are primarily used for patients who are at high risk for traditional pacemakers and do not require dual-chamber pacing.
- Some medical procedures, such as lithotripsy, hyperbaric chamber, and electrocautery used during surgery, may require pacemaker programming and testing perioperatively.
- Table 3 describes the five-letter pacemaker code, and Table 4 summarizes common permanent pacemakers.

RELATED CONTENT

Complete Heart Block (Patient Information)

AUTHOR: **John Wylie, MD, FACC**

TABLE 2 Complete Heart Block Management

Setting	Therapy
Asymptomatic–Acquired	• Rule out reversible causes, including: Hyperkalemia Acute inferior MI Digoxin toxicity Excess calcium channel blocker therapy Lyme disease • If HR <40 bpm, first-line therapy is a permanent DDD pacemaker. • Temporary pacing is indicated if heart rate <40 bpm. The patient has impaired hemodynamics, and if permanent, pacing cannot be accomplished expeditiously. The CHB has an identifiable and reversible cause, while awaiting recovery. Temporary transvenous pacing must be used with caution in patients with any escape rhythm, particularly if wide QRS complex and slow. Overdrive suppression can occur rapidly. • If the rate of escape rhythm >40 bpm, permanent pacemaker insertion is controversial. • Temporary pacing is to be avoided in asymptomatic patients whose ventricular rates are >40 bpm, especially if the QRS complex is narrow. • CHB due to radio frequency ablation of the AV junction to control ventricular response rate in atrial fibrillation requires permanent pacing. May occur even if the patient is asymptomatic from a slow ventricular rate (40 bpm) that may be quite stable over time. Acquired CHB is associated with a poor short-term prognosis (>50% mortality in the first 6-12 mo after diagnosis). If irreversible, pacing is indicated.
Symptomatic	• A permanent pacemaker is indicated. • Temporary pacing is indicated if permanent pacing cannot be done expeditiously or if CHB has an identifiable and reversible cause (e.g., drug overdose).
Congenital	• Usually associated with a narrow QRS complex with an escape rhythm arising in the AVN. • Patients are usually asymptomatic. • In patients who are asymptomatic, the indications for a pacemaker are controversial. • Patients will need close follow-up, at least annually, for evaluation of symptoms suggesting chronotropic incompetence. • If symptomatic bradycardia, a permanent pacemaker is indicated. • If rate is consistently <50 bpm and does not increase with exercise (chronotropic incompetence), a permanent pacemaker is indicated.
MI	• If symptomatic bradycardia, a temporary pacemaker is indicated. • If CHB block occurs in the setting of an anterior infarction, permanent pacing is indicated if AVB persists. • CHB in inferior MI is generally in the AVN. There is usually no need for a permanent pacemaker, as it usually resolves. If it does not resolve, a permanent pacemaker may be indicated in some cases.
Preoperative	• Permanent pacemaker first, unless the surgery is emergent. • If surgery is emergent, insert a temporary pacemaker pre-op with the plan for a permanent pacemaker after surgery.
Postoperative	• Transcutaneous or temporary transvenous pacing. • A permanent pacemaker is indicated if there is permanent damage to the AV conduction system (e.g., after aortic valve surgery or VSD repair).

AV, Atrioventricular; *AVB,* atrioventricular block; *AVN,* atrioventricular node; *bpm,* beats per minute; *CHB,* complete atrioventricular block; *HR,* heart rate; *MI,* myocardial infarction; *VSD,* ventricular septal defect.

O = none	O = none	O = none	C = communicating	
			O = none	

*In the triggered response mode, the pacemaker discharges or fires when it recognizes an intrinsic depolarization. As a result, pacemaker spikes occur during inscription of the QRS complex. Because this mode results in high energy consumption and a shortened battery life and because the sensing response can be misinterpreted as pacemaker malfunction, this sensing mode is not used with modern pacemakers.
From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, WB Saunders.

TABLE 4 Common Permanent Pacemakers

Code	Indication	Advantages	Disadvantages
VVI	Intermittent backup pacing; inactive patient	Simplicity; low cost	Fixed rate; risk of pacemaker syndrome
VVIR	Atrial fibrillation	Rate responsive	Requires advanced programming
DDD	Complete heart block	Atrial tracking restores normal physiology	No rate responsiveness; requires two leads and advanced programming
DDDR	Sinus node dysfunction; for rate responsiveness atrioventricular block and need	Universal pacer; all options available by programming	Complexity, cost, programming, and follow-up evaluation

Heart Block, Second-Degree PTG

BASIC INFORMATION

DEFINITION

Second-degree heart block or second-degree atrioventricular (AV) heart block is characterized by a failure of one or more, but not all, atrial impulses to conduct to the ventricles. The block may be at any level of the AV conduction system. In both types of second-degree heart block, the sinus rate will continue at regular intervals, resulting in a constant sinus rate. When more than one atrial impulse is present for each ventricular complex, the rhythm may be described as a ratio of the number of atrial impulses to the number of ventricular complexes. Electrocardiographically there are three types of second-degree block:

- Mobitz I (Wenckebach):
  1. Characterized by a progressive prolongation of the PR interval prior to a blocked nonconducted beat and a shorter PR interval after that blocked beat; the conducted impulse will generally be narrow. The cycle may repeat periodically, leading to "grouped beating."
  2. Site of block is usually AV node (proximal to the His bundle).
- Mobitz type II:
  1. Characterized by fixed PR intervals before and after blocked beats and may be associated with a wide QRS morphology (right bundle branch block [RBBB] or left bundle branch block [LBBB] patterns).
  2. Site of block is usually infranodal, especially when QRS is wide.
  3. It has a greater propensity for progressing to third-degree AV block.
- Pure 2:1 conduction patterns cannot be reliably classified as Mobitz type I or type II because there are not enough P waves to characterize prolongation of the PR interval.

SYNONYMS

Wenckebach block (Mobitz type I block)
Mobitz type II block
AV block

ICD-10CM CODES

I44.1	Atrioventricular block, second degree
I45.5	Other specified heart block
Q24.6	Congenital heart block

EPIDEMIOLOGY & DEMOGRAPHICS

Mobitz type I block is more common and may occur in individuals with heightened vagal tone or as a side effect of medications, such as β-blockers or calcium channel blockers.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with Mobitz type I are usually asymptomatic. Patients with either type may feel palpitations or the feeling of "missing a beat." Sudden loss of consciousness without warning (Adams-Stokes attack) can occur in patients with Mobitz type II; however, it is much more common in patients with complete heart block.
- Type I block: There is gradual decrease in the intensity of the first heart sound with widening of the a-c interval in the central venous waveform, ending in a pause, and an a wave not followed by a v wave in the neck along with an irregular pulse.
- Type II block: The first heart sound retains a constant intensity, with intermittent ventricular pauses and a waves not followed by v waves in the neck. There is an irregular pulse for most times with intermittent pauses.

ETIOLOGY

- High vagal tone (young patients, athletes at rest)
- Degenerative changes in the AV conduction system
- Ischemia at the AV nodes (type I with inferior wall myocardial infarction [MI] and type II with anterior wall MI)
- Drugs (digitalis, quinidine, procainamide, adenosine, calcium channel blockers [nondihydropyridines], β-blockers)
- Cardiomyopathies, collagen vascular diseases, infiltrative diseases (amyloidosis, sarcoidosis, hematochromatosis)
- Myocarditis/endocarditis (infectious, e.g., Lyme disease, Chagas disease; and noninfectious, e.g., systemic lupus erythematosus)
- Hyperkalemia, hypermagnesemia
- Hypothyroidism
- Prior cardiac valve surgery
- Catheter trauma, catheter ablation for arrhythmias

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The ECG easily and reliably distinguishes Mobitz type I from Mobitz type II block and from other conduction abnormalities. It should be distinguished from the less common phenomenon of second-degree sinoatrial node exit block.

Mobitz type I block with a normal QRS complex tends to be benign and usually does not progress to more advanced forms of AV conduction within a short period of time because the disease is mostly confined to within the AV node. Mobitz type II block often precedes the development of Adams-Stokes syncope, symptoms are frequent, prognosis is compromised, and progression to third-degree AV block is common and sudden. Thus, type II second-degree AV block with a wide QRS typically indicates diffuse conduction system disease involving even the infranodal His-Purkinje system.

WORKUP

ECG, ambulatory monitoring (Holter or external loop recorders) in selected patients

- Mobitz type I (Fig. 1) ECG shows:
  1. Sequential and gradual prolongation of PR interval leading to a nonconducted P wave
  2. Shortened PR interval following the pause as compared with the pre-pause PR interval
  3. Progressive shortening of the R-R interval prior to nonconducted atrial impulse
  4. Usually see "grouped beating" pattern
- Mobitz type II ECG shows (Fig. 2):
  1. Fixed duration of PR interval with constant P-P and R-R intervals
  2. Sudden nonconducted P wave
  3. Abnormal QRS duration or fascicular blocks are common
- In 2:1 AV block (Fig. 3), it cannot be determined based on the 12-lead ECG whether there is Mobitz type I or type II AV block, although a wide QRS complex is suggestive of Mobitz type II.
  1. Administering atropine can improve AV conduction if the AV block is type I or within the AV node; however, if it is infranodal (i.e., type II), the increased sinus rate caused by atropine may worsen the ratio of AV conduction, resulting in worsening bradycardia.
  2. Exercise stress testing may function in the same way as atropine above. If the disease is confined to the AV node, it may improve with exercise, but in cases of Mobitz type II AV block, the degree of AV block will worsen.
  3. Carotid sinus stimulation and other vagal maneuvers may worsen the AV block if it is at the level of the AV node (i.e., Mobitz type I) but will paradoxically improve the ratio of AV conduction by slowing down the sinus rate if it is a Mobitz type II or infranodal AV block.
  4. An algorithm for evaluation of patients with 2:1 AV block is illustrated in Fig. 4.

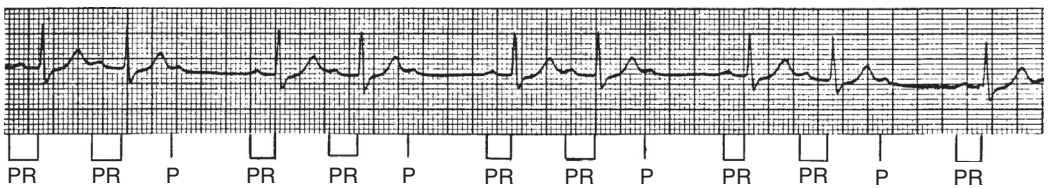

FIG. 1 Wenckebach (Mobitz type I) second-degree atrioventricular block. Notice the progressive increase in PR intervals, with the third P wave in each sequence not followed by a QRS. Wenckebach block produces a characteristically syncopated rhythm with grouping of the QRS complexes (group beating).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Elimination of drugs that may induce AV block such as digoxin, beta-blockers, and calcium channel blockers

ACUTE GENERAL Rx

- Treatment is usually not necessary unless the resting heart rate is <40 beats per min (bpm) while awake.
- If symptomatic (e.g., dizziness), atropine 1 mg (may repeat once after 5 min) may be tried to increase AV conduction; if no response, trial of dobutamine or isoproterenol may be helpful prior to insertion of a pacemaker.
- Atropine:
  1. Reduces heart block due to hypervagotonia but not due to AV node ischemia
  2. Does not increase infranodal conduction (third-degree and second-degree AV block that is below the AV node)
  3. Should be used with caution in Mobitz type II AV block due to possible paradoxical decrease in heart rate (as atrial rate increases, AV conduction decreases)
  4. Is ineffective in heart transplantation patients
- If associated with anterior wall MI and wide QRS complex, consider insertion of a temporary pacemaker.
- Indications for permanent pacemaker (PPM) implantation by ACC/AHA/HRS 2008 guidelines:
  1. Second-degree AV block with associated symptomatic bradycardia regardless of the type or site of the block (class I; level of evidence: B)
  2. Second-degree AV block provoked by exercise in the absence of myocardial ischemia (class I; level of evidence: C)
  3. Asymptomatic second-degree AV block at intra- or infra-His levels found at electrophysiologic study (class IIa; level of evidence: B)
  4. First- or second-degree AV block with symptoms similar to those of pacemaker syndrome or hemodynamic compromise (class IIa; level of evidence: B)
  5. Asymptomatic type II second-degree AV block with a wide QRS, including isolated right bundle branch block (class I; level of evidence: B)

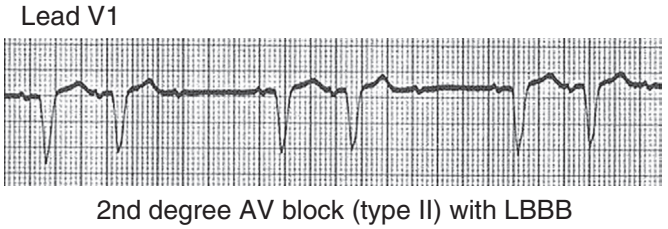

FIG. 2 Mobitz type II atrioventricular (AV) block with left bundle branch block (LBBB). Note the fixed P-P intervals with no change in PR intervals followed by a sudden nonconducted P wave. The LBBB indicates infranodal disease in the His-Purkinje system that is suggestive of Mobitz type II block.

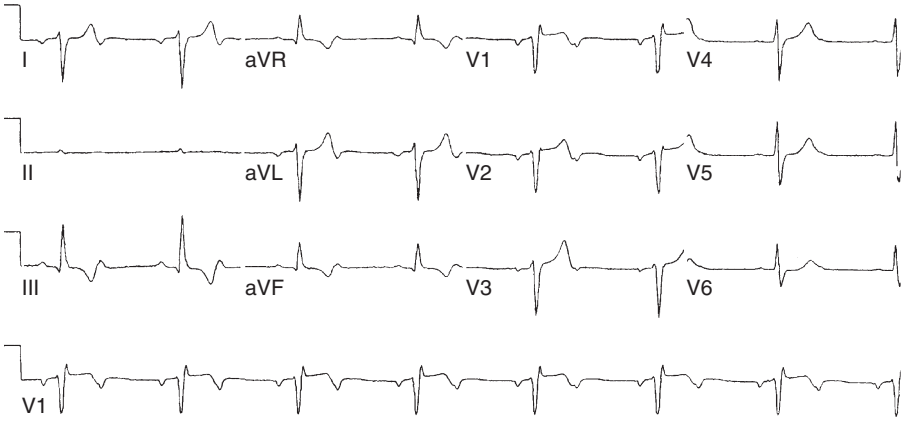

FIG. 3 Second-degree 2:1 atrioventricular block. Notice the short PR interval during conducted complexes and the wide QRS complexes, suggesting block in the His-Purkinje system. (From Issa Z et al: *Clinical arrhythmology and electrophysiology,* ed 2, Philadelphia, 2012, WB Saunders.)

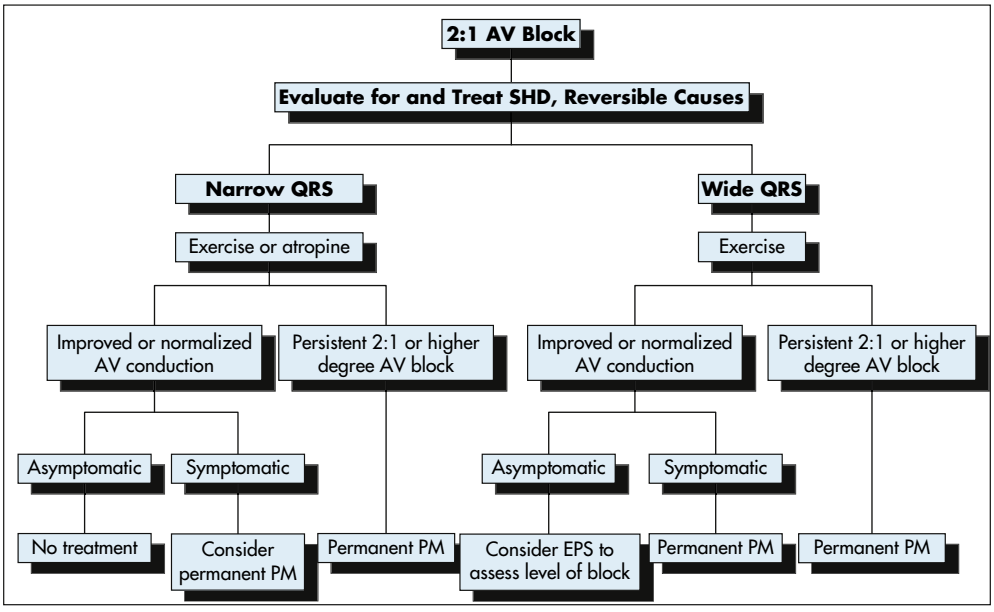

FIG. 4 Evaluation and management of 2:1 AV block. *AV*, Atrioventricular; *EPS*, electrophysiology study; *PM*, pacemaker; *SHD*, structural heart disease (no overt evidence of myocardial, valvular, congenital, or coronary heart disease.) (From Olshansky B et al: *Arrhythmia essentials*, ed 2, Philadelphia, 2017, Elsevier.)

6. PPM is not indicated for asymptomatic type I second-degree AV block at supra-His (AV node) level or that which is not known to be intra- or infra-Hisian (class III; level of evidence: C)

- Table 1 summarizes the management of Mobitz type I second-degree AV block.
- Table 2 summarizes the management of Mobitz type II second-degree AV block.

DISPOSITION

Prognosis is good with insertion of a pacemaker.

REFERRAL

Referral for pacemaker insertion (see "Acute General Rx")

PEARLS & CONSIDERATIONS

COMMENTS

Patients with symptomatic Mobitz type II should be referred for a pacemaker. Asymptomatic patients should be referred if the AV block worsens with exercise and should be followed up routinely for potential development of high-grade AV block.

Second-Degree Heart Block (Patient Information)

AUTHOR: **Aleem I. Mughal, MD**

TABLE 1 Mobitz Type I Second-Degree Atrioventricular Block Management

Setting	Therapy

Outpatient—Asymptomatic	• Treadmill testing will help assess chronotropic competence (if this rhythm is not related to myocardial ischemia), as well as enhance AVN conduction, thereby reducing the degree of Wenckebach block (e.g., from 5:4 to 8:7 or producing first-degree AVB only).
	• Holter monitoring can assess the degree and level of AVB and the persistence of the problem during activities of daily living and any diurnal variation.
	• If the QRS duration is wide and Holter monitoring or stress testing suggests infranodal block, an electrophysiology study may help to confirm the level of AVB.
	• If block is demonstrated to be intra- or infra-Hisian, permanent pacemaker implantation is reasonable, even in an asymptomatic patient. On occasion, intra-Hisian block can be demonstrated in a patient with a narrow, normal-appearing QRS complex by the production of higher degrees of AV block during treadmill testing with the increase in sinus rate.
	• No therapy.
	  • If not due to reversible cause (e.g., drugs or transient damage to the AV node from Lyme disease) and the QRS duration is normal, as more advanced or complete heart block rarely develops.
	  • There may be increased risk of syncope and symptoms in the future.

Outpatient—Symptomatic	• Some AV nodal blocking drugs (digoxin, β-adrenergic blockers, calcium blockers) may be the cause and should be reduced or stopped, if possible, and then only if severe symptomatic bradycardia occurs.
	• If older or at high risk for structural heart disease, consider an echocardiogram to assess LV function (even if no physical findings are present).
	• If due to a correctable cause such as AV nodal blocking drugs, stop the drug, if possible.
	• If there is a wide QRS or bundle branch block, it is possible that Wenckebach can be due to a block below the AV node (in the His-Purkinje system).
	  • In this case, permanent pacemaker implantation is indicated.
	  • Acutely, intravenous atropine or oral theophylline usually increases conduction through the AV node.
	  • These may paradoxically decrease ventricular rate and increase the degree of block if the block is below the bundle of His.
	• Permanent pacemaker implantation is indicated if symptomatic second-degree AVB is not otherwise correctable.

MI	• Is often reversed during thrombolysis or angioplasty.
	• May also appear for the first time concomitantly with these procedures.
	• Transient in nature
	• Temporary DDD pacing for the following:
	  • Persistent low heart rate (<40 bpm)
	  • Low cardiac output
	  • Ischemia
	  • Refractory hypotension
	  • Symptoms of light-headedness and dizziness
	• Atropine or theophylline may reverse the block but can cause unwanted tachycardia during drug administration.
	• These drugs are only rarely indicated except at the time of presentation of the patient.
	• Atypical AV block is more common in inferior-posterior MIs due to the Bezold-Jarisch reflex and the effect of increased vagal tone on the AV node.
	  • This is usually transient, and unless there is hemodynamic collapse, there is no need for a temporary pacemaker.
	  • Rarely is there a need for a permanent pacemaker. This is true even if transient third-degree (complete) AV block occurs, as high degrees of block tend to resolve over 5-7 days.
	  • If the AV block does not resolve but the ventricular rate is >40 bpm, no therapy is required if patient is asymptomatic.
	  • If the block does not resolve after 7 days and/or the ventricular rate is <40 or if patient is symptomatic, a permanent pacemaker is indicated.

Preoperative	• Assess drugs given and their need; stop offending drugs that enhance vagal tone, if possible. • If no symptoms, no therapy. • If symptomatic and no reversible causes, provide temporary pacing before surgery. • Need for permanent pacing can be accomplished in the postoperative setting. • Atropine or isoproterenol may be given to increase AV node conduction if symptomatic or hemodynamically significant.
Postoperative	• Rare after CABG but, if it occurs, consider an offending drug or transient ischemia to the AV node. • No therapy is generally needed. • If associated with wide QRS complex, consider block below the His. • If it persists, consider an EP study to assess the level of the block. • If patient is asymptomatic and block is above His, no need for permanent pacemaker. • If patient is symptomatic or block is below the His, permanent pacemaker is indicated. • If the block is associated with valve (especially aortic) surgery, consider direct damage to the AV node. • If persistent, a pacemaker is indicated for symptoms or persistent slow rate (<40 bpm or no increase in rate with exercise).

AV, Atrioventricular; *AVB*, atrioventricular block; *AVN*, atrioventricular node; bpm, beats per minute; *CABG*, coronary artery bypass graft; *DDD*, dual-chamber; *EP*, electrophysiology; *LV*, left ventricular; *MI*, myocardial infarction.

TABLE 2 Mobitz Type II Second-Degree Atrioventricular Block Management

Setting	Therapy

Outpatient—Asymptomatic	• Risk for complete heart block and death is significant (approximately 50%).
	• A dual-chamber permanent pacemaker is recommended as the pacing system of choice.
	  • Admit the patient for a permanent pacemaker and place on a cardiac monitor.
	  • In the absence of symptoms or progressive (higher-degree AVB), there is no need for a temporary pacemaker before permanent pacemaker implantation.
	  • Avoid atropine.
	  • Evaluate for the presence of underlying cardiac disease, such as infiltrative processes (e.g., amyloid) or MI.

Outpatient—Symptomatic	• Dual-chamber permanent pacemaker implantation is indicated.
	• Admit the patient and place on a cardiac monitor.
	  • If symptomatic or hemodynamically detrimental ventricular bradycardia is present, a temporary pacemaker is indicated if a permanent system cannot be placed expeditiously.
	  • Do not give atropine because this may worsen the AVB and produce a slower ventricular rate.
	  • Exercise, sinus tachycardia, and catecholamines also can worsen the degree of block by enhancing AV nodal conduction and impinging on the refractory period of the His-Purkinje system.

MI	• Place temporary pacemaker.
	  • Mobitz type II second-degree AVB is associated with a high rate of heart failure in this setting.
	  • A permanent pacemaker is indicated if the AVB is persistent because the risk of complete heart block is >50%.
	  • Long-term prognosis may not be improved.
	  • Avoid the use of antiarrhythmic drugs (including lidocaine) in the absence of a pacemaker, unless there is sustained ventricular tachyarrhythmia, as these drugs may worsen the degree of AVB.
	  • Do not give atropine.
	  • Mobitz type II second-degree AVB has a lower (albeit not known with certainty) incidence in the current early revascularization era, but if present or of new onset may improve with time, but this is rare. After being present and persistent, a pacemaker will likely be needed.

Preoperative	• Place permanent pacemaker.
	  • If urgent or emergent surgery, place a temporary pacemaker with the plan for a permanent pacemaker after surgery.
	  • If CABG, epicardial atrial and ventricular wires can be placed, with temporary pacing as standby, until a permanent transvenous pacemaker can be placed.
	  • It is best to place the permanent pacemaker after CABG or other cardiac surgery as leads otherwise tend to dislodge.
	  • If endocarditis, temporary pacemaker until infection resolves and after cardiac surgery.
	  • Avoid antiarrhythmic drugs and atropine.

Postoperative	• If bradycardia, temporary pacing (via epicardial wires, if present, after cardiac surgery).
	• Temporary Mobitz type II AV block may resolve after cardiac surgery.
	  • It may be due to trauma near the His-Purkinje system (e.g., with aortic valve surgery, where left bundle branch block is a not-infrequent accompaniment).
	  • Persistent (e.g., more than 3-5 days) Mobitz type II block will require permanent pacing.
	  • No antiarrhythmic drugs should be given unless an adequate backup ventricular pacing is available.
	  • Endocarditis with abscess near the septum can destroy the His-Purkinje system.
	  • Despite surgical repair, permanent pacing will likely be required.
	  • For patients having tricuspid valve replacement, an endocardial lead can occasionally be placed across a porcine bioprosthesis without producing tricuspid regurgitation but should be avoided if there is a mechanical valve.
	  • Tricuspid valve repair (e.g., annuloplasty) should not pose a problem in positioning a right ventricular lead.

BASIC INFORMATION

DEFINITION

Heart failure (HF) is a complex clinical syndrome that can result from any structural or functional cardiac disorder that impairs the ability of the ventricle to fill with or eject blood. The cardinal manifestations of heart failure are dyspnea, fatigue, and fluid retention. The pathophysiology of HF (Fig. E1) is related to progressive activation of the neuroendocrine system to compensate for decreased effective circulating volume (Table 1), leading to total body volume overload and circulatory insufficiency. These events culminate in the development of pulmonary congestion as well as peripheral edema. Specifically, the renin-angiotensin-aldosterone system (RAAS) is implicated; once activated, it can lead to volume expansion (sodium retention) and cardiac fibrosis (mediated through angiotensin II). Another recognized mechanism is disordered adrenergic stimulation as a key component of progression of disease. The term *congestive heart failure* (CHF) usually denotes a volume-overloaded status as a result of HF. Given that not all patients have volume overload at the time of the evaluation, *congestive heart failure* should be distinguished from the broader term *heart failure*.

CLASSIFICATION: The American College of Cardiology/American Heart Association (ACC/AHA) describes the following four stages of HF. This staging model was designed to emphasize the evolution and progression of HF over a continuum and the preventability of HF in at-risk patients.

Stage A: Patients at high risk (e.g., with hypertension, atherosclerotic disease, diabetes mellitus, metabolic syndrome, cytotoxin, family history) for HF but without structural heart disease or symptoms of HF

Stage B: Patients with structural heart disease (e.g., left ventricular [LV] dysfunction) but without symptoms of HF

Stage C: Patients with structural heart disease with prior or current symptoms of HF

Stage D: Patients with refractory HF requiring specialized interventions

In addition to the ACC/AHA stages described above, the New York Heart Association (NYHA) defines four functional classes of HF designed to describe the symptoms of stage C and D HF. The functional classes are intended to assess the symptoms of HF and may fluctuate with therapy. It should be noted that current guidelines employ the functional classes to aid in determination of appropriate treatment.

I. Asymptomatic or symptomatic only at activity levels that would limit normal individuals

II. Symptomatic with ordinary exertion (e.g., 2 city blocks or 1 flight of stairs in a faster than usual pace)

III. Symptomatic with less than ordinary exertion (e.g., less than 2 city blocks or 1 flight of stairs)

IV. Symptomatic at rest

Table 2 compares the ACC/AHA and the NYHA classification. Table 3 describes a simplified classification and common clinical characteristics of patients with acute heart failure.

TERMINOLOGY: Although HF has traditionally been classified as systolic vs. diastolic, this was dependent on the imaging modality used. With noted variation in the observed systolic function between studies, the ejection fraction serves as a better marker. HF is now categorized into *HF with reduced ejection fraction* (HFrEF) and HF with *preserved ejection fraction* (HFpEF). Other common classifications include right-sided vs. left-sided and high-output vs. low-output. Systolic HF or HFrEF is defined by the presence of impaired contractility of the LV, as measured by ejection fraction (EF) ≤40% with clinical signs or symptoms of HF. In contrast, HFpEF has been described as evidence (clinical) of HF with an EF ≥50% with or without evidence of diastolic dysfunction. There are two further classifications of HFpEF: HFpEF borderline, used to describe patients with an EF 41% to 49%, and HFpEF improved, used to describe patients who previously had HFrEF with an improvement in their EF.

Right-sided HF denotes peripheral signs and symptoms of HF without evidence of pulmonary congestion, as opposed to left-sided HF, which typically manifests with pulmonary congestion and subsequent signs and symptoms of right-sided HF. The most common cause of right-sided HF is left-sided HF. High-output HF involves signs and symptoms of HF but features an elevated cardiac output unable to meet the abnormally high metabolic demands of peripheral tissues and is the result of myriad systemic disorders (e.g., systemic arteriovenous fistulas, hyperthyroidism, anemia). The term *acute decompensated HF* (ADHF) refers to worsening of signs or symptoms of HF due to a wide range of causes. Of note, HF is not equivalent to cardiomyopathy or LV dysfunction. These latter terms describe the possible structural or functional reasons for the development of HF, whereas HF is a clinical syndrome characterized by specific symptoms and signs.

I50.9	Heart failure, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- There is variability in the reported demographics of HF due to heterogeneous definitions and classifications of HF. Incidence rate is lowest among white women and highest among black men. African Americans have the highest risk for HF of the demographic groups with blacks having a higher 5-yr mortality rate than whites.
- The lifetime risk of developing HF is 20% for Americans ≥40 yr of age.
  1. In the U.S., HF incidence has largely remained stable over the past several decades, with >650,000 new HF cases diagnosed annually.
  2. There has been an increase in the prevalence of HF in the population over time. This is primarily due to improved treatment of hypertension and valvular and coronary disease, allowing patients to survive an early death only to later develop HF.
- HF is primarily a condition of the elderly. Approximately 80% of patients hospitalized with HF are older than 65 yr. HF is the most common inpatient diagnosis in the U.S. for patients aged >65 yr.
- HF incidence increases with age, rising from approximately 20 per 1000 individuals 65 to 69 yr to >80 per 1000 individuals among those >85 yr. Before age 75, the incidence of HF is higher in males, but both sexes are equally affected after this age cutoff.
- In the U.S., 1.1 million hospital discharges and 3.2 million hospitalizations/ambulatory care visits were associated with HF in 2007.
- Prevalence: 5.1 million persons in the U.S. and an estimated 23 million persons worldwide. The prevalence of HF is rising, especially in the elderly, particularly due to aging of the population and improved survival from other conditions.
- The estimated (direct and indirect) cost of HF in the U.S. was >$40 billion in 2012, with over half of these costs spent on hospitalizations. The mean cost of HF-related hospitalizations is $23,077 per patient and is higher when HF was a secondary rather than the primary diagnosis.
- HFrEF and HFpEF each make up about half of the overall HF burden.
- Among patients with HF in one large population study, hospitalizations were common

TABLE 1 Compensatory Mechanisms in Heart Failure

Compensatory Response	Stimuli	Beneficial Effects	Adverse Effects	Potential Pharmacologic Interventions
Renin-angiotensin system activation	↓CO/BP ↓Renal blood flow ↑β-adrenergic activity	Maintain vital organ perfusion through vasoconstriction and sodium retention	↑Afterload → worsened LV function Adverse LV remodeling (apoptosis, myocyte hypertrophy)	ACE inhibitors ARBs
Adrenergic activation	↓CO/BP	↑CO through ↑ in heart rate and contractility ↑BP	↑Ischemia ↑Afterload → worsened LV function ↑LVEDP → pulmonary congestion Adverse LV remodeling (apoptosis, myocyte hypertrophy)	β-adrenergic blocking agents
Renal salt and water retention	↑Antidiuretic hormone ↑Norepinephrine ↑Angiotensin II ↑Aldosterone ↓Renal blood flow	↑Preload → ↑stroke volume and CO	Pulmonary and systemic congestion Adverse LV remodeling	Diuretics Aldosterone inhibitors ACE inhibitors, ARBs β-adrenergic blocking agents

TABLE 2 American College of Cardiology/American Heart Association (ACC/AHA) Stages of Heart Failure (HF) Compared to the New York Heart Association (NYHA) Functional Classification

ACC/AHA Stages		NYHA Functional Classification	
A	At high risk for HF but without structural heart disease or symptoms of HF.	None	
B	Structural heart disease but without signs or symptoms of HF.	I	No limitation of physical activity. Ordinary physical activity does not cause symptoms of HF.
C	Structural heart disease with prior or current symptoms of HF.	I	No limitation of physical activity. Ordinary physical activity does not cause symptoms of HF.
		II	Slight limitation of physical activity. Comfortable at rest, but ordinary physical activity results in symptoms of HF.
		III	Marked limitation of physical activity. Comfortable at rest, but less than ordinary activity causes symptoms of HF.
D	Refractory HF requiring specialized interventions.	IV	Unable to carry on any physical activity without symptoms of HF, or symptoms of HF at rest.

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

after HF diagnosis, with 83% of patients hospitalized at least once and 43% hospitalized at least 4 times. More than half of the hospitalizations were related to noncardiovascular causes.

RISK FACTORS

Several conditions are associated with an increased risk of developing heart failure. If these are identified and treated appropriately, it may be possible to delay, if not prevent, the onset of HF.

- Hypertension: The incidence of HF is higher in patients with higher blood pressures, older age of the hypertensive patient, and in patients who have been hypertensive for longer.
- Diabetes mellitus: The incidence of HF is increased in patients with diabetes mellitus, independent of the presence of structural heart disease.
- Metabolic syndrome: Appropriately treating hypertension, diabetes mellitus, and dyslipidemia can decrease the incidence of HF.
- Atherosclerotic disease: Patients with atherosclerotic disease are likely to develop HF.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The clinical and physical exam findings should be given the highest priority when determining the diagnosis of HF. These signs and symptoms are dependent on the severity of disease, precipitant factors, comorbid conditions, and whether the HF symptoms are predominantly right-sided or left-sided. Clues in the patient's history when evaluating HF are summarized in Table 4.

- Common clinical manifestations are:
  1. Dyspnea on exertion, that can progress to dyspnea at rest, caused by increasing pulmonary vascular congestion
  2. Orthopnea, caused by increased venous return in the recumbent position and further elevated pulmonary venous pressure
  3. Paroxysmal nocturnal dyspnea (PND) resulting from multiple factors including increased venous return in the recumbent position, decreased PaO_2, and decreased adrenergic stimulation of myocardial function during sleep
  4. Nocturnal angina resulting from increased myocardial oxygen demand (secondary to increased venous return in the recumbent position causing increased preload) in patients with concomitant coronary artery disease (CAD)
  5. ***Cheyne-Stokes respiration*** (alternating phases of apnea and hyperventilation) caused by prolonged circulation time from lungs to brain as a result of impaired cardiac output
  6. Fatigue, lethargy, and decreased functional capacity resulting from low cardiac output and hypoperfusion of peripheral tissues
  7. Table 5 summarizes common presenting symptoms and signs of decompensated heart failure.
- Physical examination (Table 6):
  1. Fine pulmonary crackles, wheezes, tachypnea, hypoxia (due to elevated pulmonary pressures). Crackles may be absent in chronic and longstanding high pulmonary venous pressure because it allows for lymphatic drainage in the lungs to increase.

TABLE 3 Simplified Classification and Common Clinical Characteristics of Patients with Acute Heart Failure

Clinical Classification	Symptom Onset	Triggers	Signs and Symptoms	Clinical Assessment	Course
Decompensated heart failure	Usually gradual	Noncompliance, ischemia, infections	Peripheral edema, orthopnea, dyspnea on exertion	SBP: Variable CXR: Often clear despite elevated filling pressures	Variable, high rehospitalization rate
Acute hypertensive heart failure	Usually sudden	Hypertension, atrial arrhythmias, ACS	Dyspnea (often severe), tachypnea, tachycardia, rales common	SBP: High (>180/100 mm Hg) CXR with pulmonary edema Hypoxemia common	High acuity, but patient often responds quickly to therapy with vasodilators, noninvasive ventilation Postdischarge mortality is low
Cardiogenic shock	Variable	Progression of advanced HF or major myocardial insult (e.g., large AMI, acute myocarditis)	End-organ hypoperfusion; Oliguria, confusion, cool extremities	SBP: Low or low normal LV function usually severely depressed RV dysfunction common Laboratory evidence of end-organ dysfunction (renal, hepatic)	High inpatient mortality Poor prognosis unless readily reversible cause or mechanical support, transplantation

ACS, Acute coronary syndrome; *AMI,* acute myocardial infarction; *CXR,* chest x-ray film; *LV,* left ventricular; *RV,* right ventricular; *SBP,* systolic blood pressure.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

2. Tachycardia and narrowed pulse pressure (due to increased sympathetic tone)
3. S_3 gallop, paradoxical splitting of S_2, jugular venous distention, peripheral edema in dependent tissues, congestive hepatomegaly, ascites, and hepatojugular reflux (due to volume overload)
4. Perioral and peripheral cyanosis, decreased capillary refill, pulsus alternans, and cool extremities (due to decreased cardiac output)

- Six common clinical presentations identified by European Society of Cardiology of Acute Heart Failure Syndromes:
  1. ADHF presenting with hypertension (SBP >160): The hypertension leads to increased afterload causing pulmonary vascular congestion
  2. Worsening or decompensation of chronic HF
  3. Flash pulmonary edema
  4. Cardiogenic shock
  5. Acute coronary syndrome (ACS) and ADHF
  6. Isolated RV failure
- Each of these scenarios may require different therapies to effectively stabilize and treat the patient.

Acute precipitants of HF decompensation include noncompliance with salt restriction or medications (most common cause), any acute systemic illness, infection, arrhythmias (e.g., atrial fibrillation), ischemia or infarction, uncontrolled hypertension, new medications (e.g., negative inotropic agents such as calcium channel blockers/antiarrhythmic agents), nonsteroidal antiinflammatory drugs (NSAIDs), renal dysfunction, toxins (e.g., ethanol and anthracyclines), surgery, or valvular catastrophe.

TABLE 4 Using the Medical History to Assess the Heart Failure Patient

Symptoms Associated with HF Include:

Fatigue
Shortness of breath at rest or during exercise
Dyspnea
Tachypnea
Cough
Diminished exercise capacity
Orthopnea
Paroxysmal nocturnal dyspnea
Nocturia
Weight gain/weight loss
Edema (of extremities, scrotum, or elsewhere)
Increasing abdominal girth or bloating
Abdominal pain (particularly if confined to right upper quadrant)
Loss of appetite or early satiety
Cheyne-Stokes respirations (often reported by family rather than patient)
Somnolence or diminished mental acuity

Historical Information Helpful in Determining if Symptoms Are Caused by HF

A past history of HF
Cardiac disease (e.g., coronary artery disease, valvular or congenital disease, previous myocardial infarction)
Risk factors for heart failure (e.g., diabetes, hypertension, obesity)
Systemic illnesses that can involve the heart (e.g., amyloidosis, sarcoidosis, inherited neuromuscular diseases)
Recent viral illness or history of HIV infection or Chagas disease
Family history of HF or sudden cardiac death
Environmental and/or medical exposure to cardiotoxic substances
Substance abuse
Noncardiac illnesses that could affect the heart indirectly, including high-output states (e.g., anemia, hyperthyroidism, arteriovenous fistulas)

HIV, Human immunodeficiency virus.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

ETIOLOGY

LEFT VENTRICULAR FAILURE: The dichotomy of whether HF occurs in the setting of preserved or reduced LV systolic function plays an important role in treatment strategies. Patients with HFpEF may have significant abnormalities in active relaxation and passive stiffness of the LV as well as valvular disease. HFrEF denotes poor pump function.

- Abnormal LV systolic function:
  1. CAD (acute or chronic ischemia, myocardial infarction [MI], LV aneurysm), the most common cause of cardiomyopathy in the U.S., comprising 50% to 75% of HF patients.
  2. Increased afterload or pressure overload (severe hypertension, aortic stenosis)
  3. Increased preload or volume overload (mitral regurgitation, aortic regurgitation)
  4. Cardiomyopathy: Idiopathic, infiltrative (nonischemic)
  5. Infectious (Chagas, myocarditis)
  6. Infiltrative (amyloidosis, sarcoidosis, hemochromatosis)
  7. Toxins (ethanol, cocaine, anthracyclines)
  8. Tachycardia induced (e.g., with atrial fibrillation)
- Preserved LV systolic function (Table 7):
  1. Impaired relaxation (myocardial ischemia, diabetes mellitus, metabolic syndrome)
  2. Tachyarrhythmia (featuring reduced diastolic filling time)
  3. Restrictive cardiomyopathy (myocardial stiffness, such as hypereosinophilic syndrome, amyloidosis, hemochromatosis)

TABLE 5 Common Presenting Symptoms and Signs of Decompensated Heart Failure

Symptoms	Signs
Predominantly Related to Volume Overload	
Dyspnea (exertional, paroxysmal nocturnal dyspnea, orthopnea, or at rest), cough, wheezing	Rales, pleural effusion
Foot and leg discomfort	Peripheral edema (legs, sacral)
Abdominal discomfort/bloating; early satiety or anorexia	Ascites/increased abdominal girth; right upper quadrant pain or discomfort; hepatomegaly/splenomegaly; scleral icterus
	Increased weight
	Elevated jugular venous pressure, abdominojugular reflux
	Increasing S_3, accentuated P_2
Predominantly Related to Hypoperfusion	
Fatigue	Cool extremities
Altered mental status, daytime drowsiness, confusion, or difficulty concentrating	Pallor, dusky skin discoloration, hypotension
Dizziness, presyncope, or syncope	Pulse pressure (narrow) Proportional pulse pressure (low)
Other Signs/Symptoms of Acute Heart Failure	
Depression	Orthostatic hypotension (hypovolemia)
Sleep disturbances	S_4
Palpitations	Systolic/diastolic cardiac murmurs

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 6 Physical Findings of Heart Failure

Tachycardia
Extra beats or irregular rhythm
Narrow pulse pressure or thready pulse*
Pulses alternans*
Tachypnea
Cool and/or mottled extremities*
Elevated jugular venous pressure
Dullness and diminished breath sounds at one or both lung bases
Rales, rhonchi, and/or wheezes
Apical impulse displaced leftward and/or inferiorly
Sustained apical impulse
Parasternal lift
Third and/or fourth heart sound (either palpable and/or audible)
Tricuspid or mitral regurgitant murmur
Hepatomegaly (often accompanied by right upper quadrant discomfort)
Ascites
Presacral edema
Anasarca*
Pedal edema
Chronic venous stasis changes

*Indicative of more severe disease.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

4. High cardiac output (thiamine deficiency, anemia, thyrotoxicosis, arteriovenous malformations)
5. Increased afterload (uncontrolled hypertension, aortic stenosis, hypertrophic obstructive cardiomyopathy)
6. Hypervolemia (oliguric renal failure, iatrogenic)

RIGHT VENTRICULAR FAILURE:

- Left-sided HF
- Chronic hypoxemic pulmonary disease
- Valvular heart disease (mitral stenosis or regurgitation)
- Pulmonary embolism
- Primary pulmonary hypertension
- Right-to-left shunts that cause systemic hypoxemia (e.g., large patent foramen ovale and tetralogy of Fallot)
- Left-to-right shunts that cause volume overload (e.g., atrial and ventricular septal defects)
- Bacterial endocarditis (right-sided)
- Right ventricular infarction

DX DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- COPD, asthma
- Cirrhosis
- Nephrotic syndrome
- Venous insufficiency
- Pulmonary embolism
- ARDS (adult respiratory distress syndrome)
- Pneumonia
- Heroin overdose

WORKUP

- ACC/AHAA guidelines for initial and serial evaluation of heart failure are summarized in Table 8.
- Blood work (to diagnose potentially reversible causes, identify comorbidities, and assess disease severity):
  1. CBC (to evaluate for anemia, infections), urinalysis, blood urea nitrogen (BUN), creatinine, electrolytes (worsening hyponatremia is a marker of disease severity and is associated with higher mortality rates), liver enzymes (hepatic congestion), thyroid function (especially in the elderly or patients with comorbid atrial fibrillation or known thyroid disease).
  2. Fig. 2 illustrates the use of biomarkers in HF. B-type natriuretic peptide (BNP) is a cardiac neurohormone secreted from the ventricles in response to elevated LV end-diastolic pressure. While the sensitivity is low in asymptomatic patients, low BNP level has a negative predictive value up to 90% in symptomatic patients. An elevated BNP correlates with severity of disease and parallels closely morbidity and mortality outcome measures. N-terminal-pro-BNP (NT-pro-BNP) is the cleavage remnant of BNP. It has a longer half-life and is renally cleared, making it susceptible to alterations in renal function. A level of <300 pg/ml has an age-independent 98% negative predictive value. There are new data to suggest that BNP screening and early intervention with risk factor modification in patients at risk of developing heart failure may prevent development of left ventricular dysfunction (class IIa recommendation). Natriuretic peptide biomarkers are also useful (class IA recommendation) both for diagnosis in patients presenting with dyspnea and for prognosis in patients with acute decompensated heart failure and chronic heart failure. Measurement of baseline levels of natriuretic peptide biomarkers on admission to the hospital is useful to establish a prognosis in acutely decompensated HF, and predischarge natriuretic peptide level can be useful to establish a postdischarge prognosis. There are insufficient data to recommend natriuretic peptide biomarker–guided therapy or serial measurements for the purpose of reducing hospitalization or deaths. ACC/AHA/HFSA guidelines for the use of biomarkers in HF are summarized in Table 9.
  3. Cardiac biomarkers may be elevated if ischemia is the precipitant factor. However, slight elevations are very common and may not always be due to obstructive coronary artery disease. These elevations could be due to subendocardial ischemia (due to increased end-diastolic pressure resulting in decreased perfusion) and necrosis, or cardiomyocyte damage from the inflammatory cytokines or oxidative stress. Impaired renal function is very common, and decreased clearance of the biomarkers can contribute to their elevation. Therefore these elevations should be interpreted in the context of the clinical setting. Despite that, in patients with acute decompensated heart failure (ADHF), a positive cardiac troponin test (from whatever mechanism) is associated with worse prognosis.
  4. Screening for dyslipidemia and glucose intolerance, which are risk factors for CAD.
  5. If hemochromatosis is suspected (specifically in Northern European patients), consider checking a transferrin saturation and ferritin level.

TABLE 7 Mechanisms/Factors Contributing to the Pathophysiology of Heart Failure with Preserved Ejection Fraction

Cardiovascular

LV Structure

Concentric remodeling, LV hypertrophy

LV Function

Diastolic dysfunction: Abnormal relaxation, decreased recoil, abnormal filling, decreased distensibility, increased diastolic pressure
Systolic dysfunction: Abnormal midwall and long-axis shortening, decreased twist
Hemodynamic load
  Increased afterload and filling load
Heterogeneity
  Dyssynergy, dyssynchrony
Left atrial structure and function
  Increased LA volume and stiffness, decreased LA reservoir function, passive conduit function and active booster pump function
Ischemia
  Subendocardial and microvascular disease, impaired coronary, pulmonary, and peripheral flow reserve
Rate and rhythm abnormalities
  Chronotropic incompetence, atrial fibrillation, supraventricular tachycardia
Vascular dysfunction
  Arterial stiffening, endothelial dysfunction

Cardiomyocyte

Abnormal calcium homeostasis (↑ diastolic calcium or ↓ rate of calcium reuptake → incomplete or impaired relaxation)
  Sarcolemmal calcium channels (Na^+/Ca^{2+} exchanger and calcium pump)
  Sarcoplasmic reticulum Ca^{2+}ATPase (SERCA) abundance and function
  Proteins modifying SERCA activity: Phospholamban, calmodulin, calsequestrin abundance, and phosphorylation state
  Sarcoplasmic reticulum calcium release channels
Energetics (↓ ATP or ↑ ADP slows actin-myosin cross-bridge release)
  ADP/ATP ratio, ADP and P_i concentration, phosphocreatine shuttle function
Proteins regulating cross-bridge formation and calcium sensitivity
  Troponin C: Calcium binding
  Troponin I: Phosphorylation state
Cytoskeletal proteins
  Microtubules (increased density) → ↑ diastolic stiffness
  Titin isoforms (↑ noncompliant isoform and phosphorylation state) → ↑ diastolic stiffness

Extracellular Matrix

Collagen structure, geometry, content, collagen I/III ratio
Collagen homeostasis, synthesis, postsynthetic processing, posttranslational crosslinking, degradation
Basement membrane proteins
Bioactive proteins and peptides: MMP/TIMP, SPARC, TGF-β
Fibroblast structure, function, phenotype
Myofibroblast transdifferentiation

Extra Cardiac

Extrinsic forces (RV-LV interaction and pericardial constraint)
Peripheral muscle and ergoreflex dysfunction
Pulmonary hypertension (secondary to chronic pulmonary venous hypertension)
Neurohormonal activation
Comorbid conditions (renal dysfunction, anemia, chronic lung disease)

ADP, Adenosine diphosphate; *ATP,* adenosine triphosphate; *LA,* left atrium; *LV,* left ventricle; *RV,* right ventricle; *SPARC*, secreted protein, acidic and rich in cysteine [osteonectin]; *TGF,* transforming growth vector.
From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

6. Consider HIV testing in high-risk patients.

- Electrocardiogram (ECG):
  1. Look for signs of prior MI, chamber enlargement, hypertrophy, heart block, arrhythmia, and evidence of pericardial effusion.
  2. More than 25% of patients with HF have some form of intraventricular conduction abnormality that manifests as an increased QRS duration. The most common pattern seen is left bundle-branch block.
- Chest x-ray (Fig. 3):
  1. Evaluate for pulmonary venous congestion, pulmonary edema, pleural effusion, cardiomegaly, chamber dilation, and Kerley B lines.
- Echocardiography:
  1. Plays a critical diagnostic role in patients with HF and is useful in assessment of systolic, diastolic function in addition to assessment of valvular structure and function
- Exercise stress testing:
  1. May be useful in evaluating concomitant ischemic etiologies and assessment of degree of disability in stable compensated patients.
- Cardiac catheterization:
  1. Left heart catheterization can help to identify coronary artery disease as a cause of HF. Right heart catheterization can help to evaluate intracardiac filling pressures, estimates of valvular areas, presence of intracardiac shunts, and calculation of hemodynamic properties such as cardiac output, systemic vascular resistance, and pulmonary artery wedge pressure to further guide management.
- Cardiac MRI:
  1. Useful modality in accurately estimating EF (with less variability than conventional 2D echocardiography). MRI is also useful in excluding pericardial disease, identifying infiltrative disease, and assessing viability in cases of HF caused by underlying ischemic heart disease.

Rx TREATMENT

NONPHARMACOLOGIC GENERAL MEASURES

- Assess the etiology and severity of disease. Educate the patient and family about the nature of the disorder. Assess the home setting and if patient has social support to ensure compliance, especially for patients with dementia.
- Identify and correct precipitating factors (e.g., increased sodium load, medication noncompliance, ischemia, infections, anemia, thyrotoxicosis) and address lifestyle modification (e.g., smoking and alcohol cessation, weight reduction, avoiding use of nonsteroidal antiinflammatory drugs [NSAIDs]). Anemia is common in patients with HF. In patients with NYHA class II and III symptoms and iron deficiency, IV iron replacement may be reasonable to improve functional status and quality of life (class IIb recommendation). Treatments with erythropoiesis-stimulating agents (ESAs) have not shown improved clinical outcomes in patients with systolic HF and mild-to-moderate anemia and are thus not recommended. Table 10 describes ACC/AHA guidelines for treating patients at high risk for development of heart failure.
- Review list of medications and discontinue the ones that can contribute to HF (e.g., NSAIDs, antiarrhythmic drugs, calcium channel blockers, thiazolidinediones).
- Dietary sodium restriction of <2 g/day is commonly recommended to patients with HF and is endorsed by many guidelines.
- Restrict fluid intake to <2 L/day in patients with hyponatremia.
- Caloric supplementation should be provided to patients with advanced HF with weight loss and muscle wasting due to cardiac cachexia. Weight loss may reflect cachexia caused by the higher total energy expenditure associated with HF compared with that of healthy sedentary subjects. The diagnosis of cardiac cachexia independently predicts a worse prognosis.
- For patients with coexisting obstructive sleep apnea, continuous positive airway pressure (CPAP) may be reasonable after polysomnography (class IIb recommendation).

TABLE 8 ACC/AHA Guidelines for Initial and Serial Evaluation of Heart Failure

Class	Indication: History, Physical Examination, and Risk Scoring	Level of Evidence
I	A thorough history and physical examination should be obtained/performed in patients presenting with HF to identify cardiac and noncardiac disorders or behaviors that might cause or accelerate the development or progression of HF.	C
	In patients with idiopathic DCM, a three-generational family history should be obtained to aid in establishing the diagnosis of familial DCM.	C
	Volume status and vital signs should be assessed at each patient encounter. This includes serial assessment of weight, as well as estimates of jugular venous pressure and the presence of peripheral edema or orthopnea.	B
IIa	Validated multivariable risk scores can be useful to estimate subsequent risk of mortality in ambulatory or hospitalized patients with HF.	C
Indication: Diagnostic Tests and Biomarkers (also see below)		
I	Initial laboratory evaluation of patients presenting with HF should include complete blood count, urinalysis, serum electrolytes (including calcium and magnesium), blood urea nitrogen, serum creatinine, glucose, fasting lipid profile, liver function tests, and thyroid-stimulating hormone.	C
	Serial monitoring, when indicated, should include serum electrolytes and renal function.	C
	A 12-lead ECG should be performed initially on all patients presenting with HF.	C
	In ambulatory patients with dyspnea, measurement of BNP or N-terminal pro-B-type natriuretic peptide (NT-proBNP) is useful to support clinical decision making regarding the diagnosis of HF, especially in the setting of clinical uncertainty, and measurement of BNP or NT-proBNP is useful for establishing prognosis or disease severity in chronic HF.	A
IIa	Screening for hemochromatosis or HIV is reasonable in select patients who present with HF.	C
	Diagnostic tests for rheumatologic diseases, amyloidosis, or pheochromocytoma are reasonable in patients presenting with HF in whom there is a clinical suspicion of these diseases.	C
	BNP-guided or NT-proBNP–guided HF therapy can be useful to achieve optimal dosing of GDMT in select, clinically euvolemic patients followed in a well-structured HF disease management program.	B
IIb	The usefulness of serial measurement of BNP or NT-proBNP to reduce hospitalization or mortality in patients with HF is not well established. The measurement of other clinically available tests, such as biomarkers of myocardial injury or "fibrosis," may be considered for additive risk stratification in patients with chronic HF.	B
Indication: Noninvasive Cardiac Imaging		
I	Patients with suspected or new-onset HF, or those presenting with acute decompensated HF, should undergo a chest radiograph to assess heart size and pulmonary congestion and to detect alternative cardiac, pulmonary, and other diseases that may cause or contribute to the patient's symptoms.	C
	A two-dimensional echocardiogram with Doppler should be performed during initial evaluation of patients presenting with HF to assess ventricular function, size, wall thickness, wall motion, and valve function.	C
	Repeat measurement of EF and measurement of the severity of structural remodeling are useful to provide information in patients with HF who have had a significant change in clinical status; who have experienced or recovered from a clinical event; who have received treatment, including GDMT, that might have had a significant effect on cardiac function; or who may be candidates for device therapy.	C
IIa	Noninvasive imaging to detect myocardial ischemia and viability is reasonable in patients presenting with de novo HF who have known CAD and no angina, unless the patient is not eligible for revascularization of any kind.	C
	Viability assessment is reasonable in select situations when planning revascularization in HF patients with CAD.	B
	Radionuclide ventriculography or MRI can be useful to assess LVEF and volume when echocardiography is inadequate.	C
	MRI is reasonable when assessing myocardial infiltrative processes or scar burden.	B
III: No benefit	Routine repeat measurement of LV function assessment in the absence of clinical status change or treatment interventions should not be performed.	B
Indication: Invasive Evaluation		
I	Invasive hemodynamic monitoring with a pulmonary artery catheter should be performed to guide therapy in patients who have respiratory distress or clinical evidence of impaired perfusion in whom the adequacy or excess of intracardiac filling pressures cannot be determined from clinical assessment.	C
IIa	Invasive hemodynamic monitoring can be useful for carefully selected patients with acute HF who have persistent symptoms despite empiric adjustment of standard therapies and (a) whose fluid status, perfusion, or systemic or pulmonary vascular resistance is uncertain; (b) whose systolic pressure remains low, or is associated with symptoms, despite initial therapy; (c) whose renal function is worsening with therapy; (d) who require parenteral vasoactive agents; or (e) who may need consideration for mechanical circulatory support or transplantation.	C
	When ischemia may be contributing to HF, coronary arteriography is reasonable for patients eligible for revascularization.	C
	Endomyocardial biopsy can be useful in patients presenting with HF when a specific diagnosis is suspected that would influence therapy.	C
III: No benefit	Routine use of invasive hemodynamic monitoring is not recommended in normotensive patients with acute decompensated HF and congestion with symptomatic response to diuretics and vasodilators.	B
III: Harm	Endomyocardial biopsy should not be performed in the routine evaluation of patients with HF.	C

ACC, American College of Cardiology; *AHA,* American Heart Association; *BNP,* B-type natriuretic peptide; *CAD,* coronary artery disease; *DCM,* dilated cardiomyopathy, *ECG,* electrocardiogram; *EF,* ejection fraction; *GDMT,* guideline-directed medical therapy; *HIV,* human immunodeficiency virus; *LVEF,* left ventricular ejection fraction; *MRI,* magnetic resonance imaging.

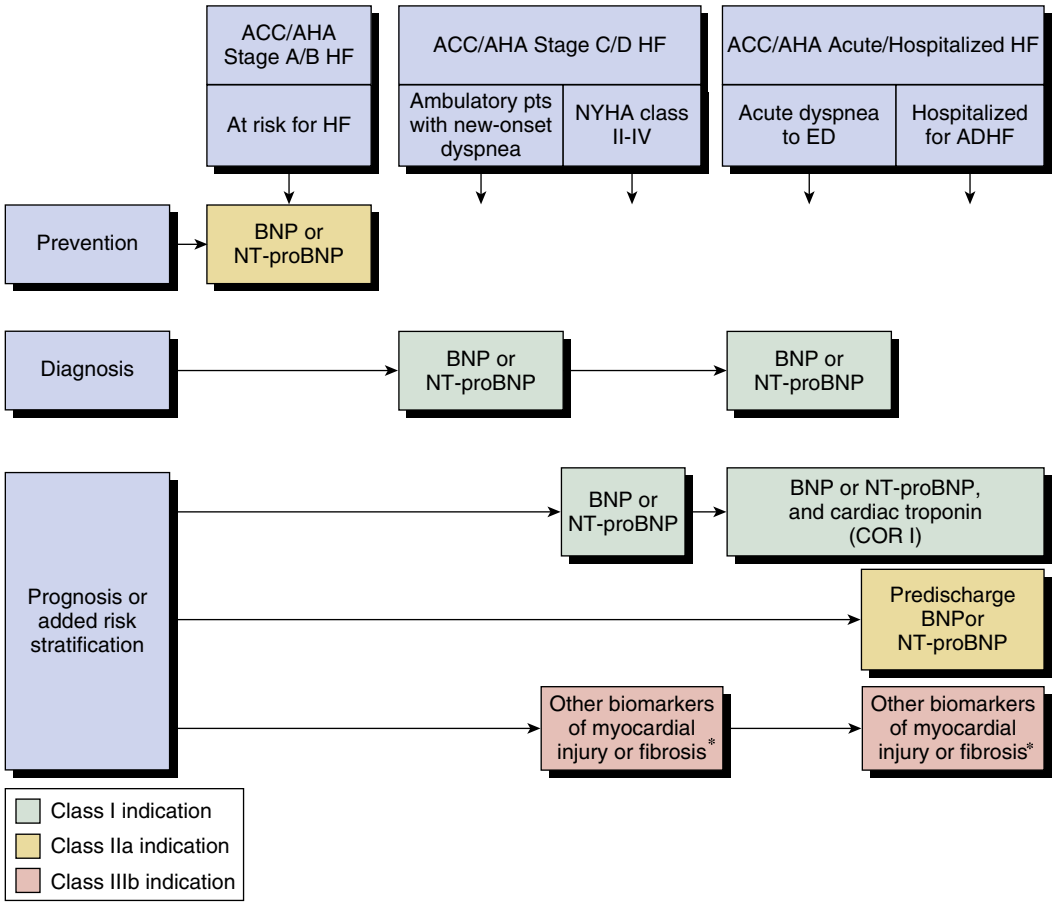

FIG. 2 Indications for the use of biomarkers in heart failure. *Other biomarkers of injury or fibrosis include soluble ST2 receptor, galectin-3, and high-sensitivity troponin. *ACC,* American College of Cardiology; *AHA,* American Heart Association; *ADHF,* acute decompensated heart failure; *BNP,* B-type natriuretic peptide; *COR,* class of recommendation; *ED,* emergency department; *HF,* heart failure; *NT-proBNP,* N-terminal pro-B-type natriuretic peptide; *NYHA,* New York Heart Association; *pts,* patients. (Modified from Yancy CW et al: 2017 ACC/AHA/HFSA focused update of the 2013 ACCF/AHA guideline for the management of heart failure: a report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines and the Heart Failure Society of America, *J Am Coll Cardiol* 2017;70[6]:776; in Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

- Exercise training (or regular physical activity) is recommended as safe and effective for patients with class I to III HF who are able to participate to improve functional status (class I recommendation). Cardiac rehabilitation is unfortunately an underused preventive measure, although it has been shown to reduce morbidity and mortality. Cardiac rehabilitation can be useful in clinically stable patients with HF to improve functional capacity, exercise duration, health-related quality of life, and mortality (class IIa recommendation).
- Pneumococcal vaccination and annual influenza vaccination.
- ACC/AHA guidelines for treatment of asymptomatic left ventricular systolic dysfunction are summarized in Table 11.

TREATMENT OF ADHF

- Four phases in treatment of ADHF:
  1st phase: Initial stabilization and management (Table 12)
  2nd phase: Inpatient hospital care (Table 13)
  3rd phase: Early discharge planning and care
  4th phase: Early postdischarge care
- 1st phase: Initial stabilization and management
- Short-term goals: Hemodynamic stabilization, stabilization of respiratory status, symptom relief, optimization of tissue perfusion, and recognition of more immediately life-threatening conditions (e.g., arrhythmias, valvular catastrophe, MI, cardiac tamponade). Initial therapy of ADHF is contingent on appropriate determination of clinical scenario.
- Management as per clinical scenario:
  1. ADHF-associated hypertension: Goal is afterload reduction and decrease of systemic hypervolemia. Mode of treatment: Diuresis (IV loop diuretics) and vasodilators (acutely nitrates and morphine followed by treatment with ACE inhibitors or angiotensin receptor blockers [ARBs])
  2. Worsening or decompensation of chronic HF (HFrEF or HFpEF): Goal is control of volume status. Treatment is accomplished with vasodilators and diuretics.
  3. Flash pulmonary edema: Goal is afterload reduction (vasodilators such as nitrates acutely), respiratory status stabilization, and diuresis (IV loop diuretics). Rate control can be initiated in patients with atrial fibrillation or tachyarrhythmias as it may improve cardiac filling and function.
  4. Cardiogenic shock: Goal is hemodynamic stabilization. Treatment consists of inotropes + vasopressors ± mechanical circulatory support ± emergent revascularization if indicated.
  5. ACS and ADHF: Goal is hemodynamic stabilization + emergent restoration of coronary perfusion. See "Acute Coronary Syndrome."
  6. Isolated RV failure: Goals are identification of etiology: (1) valvular, (2) pulmonary hypertension, and (3) primary RV failure secondary to ischemia. Treatment: depends on etiology, either corrective surgery vs. treatment of pulmonary hypertension (endothelin antagonists, calcium channel blockers, phosphodiesterase inhibitors) vs. coronary reperfusion therapies.

TABLE 9 ACC/AHA/HFSA Guidelines for Use of Biomarkers in Heart Failure

Class	Biomarkers for Prevention of HF	Level of Evidence
IIa	For patients at risk of developing HF, natriuretic peptide biomarker–based screening can be useful to prevent the development of left ventricular dysfunction (systolic or diastolic) or new-onset HF.	B-R
Biomarkers for Diagnosis		
I	In patients presenting with dyspnea (acute or chronic), measurement of natriuretic peptide biomarkers is useful to support a diagnosis or exclusion of HF.	A
Biomarkers for Prognosis or Added Risk Stratification		
I	Measurement of BNP or NT-proBNP is useful for establishing prognosis or disease severity in chronic HF.	A
I	Measurement of baseline levels of natriuretic peptide biomarkers and/or cardiac troponin on admission to the hospital is useful to establish a prognosis in acutely decompensated HF.	A
IIa	During a HF hospitalization, a predischarge natriuretic peptide level can be useful to establish a postdischarge prognosis.	B-NR
IIb	In patients with chronic HF, measurement of other clinically available tests, such as biomarkers of myocardial injury or fibrosis, may be considered for additive risk stratification.	B-NR

ACC, American College of Cardiology; *AHA,* American Heart Association; *BNP,* B-type natriuretic peptide; *HF,* heart failure; *HFSA,* Heart Failure Society of America; *NT-proBNP,* N-terminal pro-B-type natriuretic peptide.

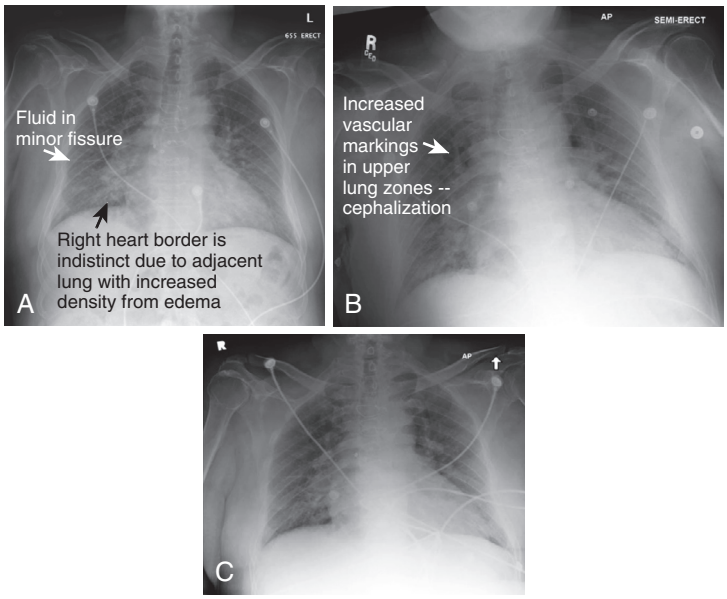

FIG. 3 Congestive heart failure. Mild left ventricular hypertrophy with restricted filling, ejection fraction >55%, and no pericardial effusion. This 63-year-old man with coronary artery disease, chronic renal insufficiency, and diastolic heart failure (ejection fraction >55%) presented multiple times for dyspnea (**A, B,** and **C,** first through third clinical presentations). Each of these three radiographs shows signs of moderate pulmonary edema. The diaphragms and costophrenic angles are clear, suggesting no pleural effusion. The right heart border in all three images is indistinct because of interstitial edema in these locations. Portions of the left heart border are also indistinct. The upper lung fields have a hazy appearance indicating mild edema. Fluid is visible in the minor fissure on all three images. Does the similarity of these radiographs mean that edema is not the cause of the patient's dyspnea? No, he simply presented with pulmonary edema on all three occasions. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, WB Saunders.)

ACUTE PHARMACOLOGIC TREATMENTS:

- Vasodilators (Table 14) are appropriate in most patients with ADHF (contraindicated in cardiogenic shock and severe aortic stenosis)
  1. Nitroglycerin (0.4 to 0.8 mg sublingually every 3 to 5 min, or by intravenous infusion starting at 0.2 to 0.4 mcg/kg/min with subsequent up titration) may be administered in the emergency setting until relative hypotension ensues. Nitrates are contraindicated after use of phosphodiesterase inhibitors such as sildenafil due to risk of hypotension.
  2. Sodium nitroprusside (0.1 to 0.2 mcg/kg/min as an intravenous infusion) is a potent vasodilator with balanced venous and arteriolar effects that usually requires hemodynamic monitoring with an arterial line and may precipitate coronary steal and thiocyanate toxicity (elevated risk in renal failure).
  3. When given intravenously, loop diuretics have an immediate vasodilator effect that provides clinical relief of symptoms before diuresis begins. Due to gut edema and unpredictable patterns of absorption, oral formulation may become less effective. Therefore intravenous formulation should be used in the acute setting. Studies showed no difference in outcome when using bolus dosing vs. continuous IV infusion. Administration of smaller doses of short-acting loop diuretics multiple times daily is preferable to a single large dose because the kidneys can avidly reabsorb sodium after the initial diuresis. However, if a certain dose is not adequate to force diuresis, the dose, rather than the frequency, should be increased until a single effective dose is reached; more frequent doses can be added as needed. Therefore monitoring of urine output, renal function, and electrolytes is key. The addition of a distal tubule inhibitor such as metolazone 30 min prior to loop diuretic dosing has a synergistic effect and often enhances diuresis because it inhibits sodium reabsorption in the distal segment in the face of increased sodium delivery from the loop. Diuretics should be used with caution in patients with aortic stenosis.
- Inotropic agents are used for temporary hemodynamic support in cardiogenic shock, but have not been shown to improve survival. Many of these agents have serious associated adverse events including myocardial necrosis and malignant arrhythmias.
  1. Dobutamine (starting at 2.5 to 5 mcg/kg/min) can be used for inotropic support but is associated with increased myocardial oxygen demand and cardiac arrhythmias and may result in hypotension from decreased systemic vascular resistance.
  2. Milrinone (37.5 to 75 mcg/kg loading dose, followed by 0.375 to 0.75 mcg/kg/min) can be used as a vasodilator and inotropic agent, but is associated with increased oxygen demand and cardiac arrhythmias, and may result in hypotension from decreased systemic vascular resistance.
- Renal replacement therapy or ultrafiltration (can be used as an alternative to pharmacologic diuresis in ADHF when renal function is significantly compromised).
- ACE inhibitors or ARBs, if part of a patient's chronic medication regimen, should be continued in the absence of hypotension, acute renal failure, or hyperkalemia.
- Beta-blockers, if part of a patient's chronic medication regimen, may be continued or reduced in dosage in mild exacerbations of

TABLE 10 ACC/AHA Guidelines for Treating Patients at High Risk of Developing Heart Failure (Stage A)

Class	Indication	Level of Evidence
I	Hypertension and lipid disorders should be controlled in accordance with contemporary guidelines to lower the risk of HF.	A
I	In patients at increased risk, stage A, the optimal blood pressure in those with hypertension should be less than 130/80 mm Hg.	B-R
I	Other conditions that may lead to or contribute to HF, such as obesity, diabetes mellitus, tobacco use, and known cardiotoxic agents, should be controlled or avoided.	C
II	For patients at risk of developing HF, natriuretic peptide biomarker–based screening followed by team-based care, including a cardiovascular specialist optimizing GDMT, can be useful to prevent the development of left ventricular dysfunction (systolic or diastolic) or new-onset HF.	B-R

ACC, American College of Cardiology; *AHA,* American Heart Association; *GDMT,* guideline-directed medical therapy; *HF,* heart failure. From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 11 ACC/AHA Guidelines for Treatment of Asymptomatic Left Ventricular Systolic Dysfunction (Stage B)

Class	Indication	Level of Evidence
I	In all patients with a recent or remote history of MI or ACS and reduced EF, ACE inhibitors should be used to prevent symptomatic HF and reduce mortality. In patients intolerant of ACE inhibitors, ARBs are appropriate unless contraindicated.	A
	In all patients with a recent or remote history of MI or ACS and reduced EF, evidence-based beta blockers should be used to reduce mortality. Beta blockade and ACE inhibition should be used in all patients with a recent or remote history of MI regardless of EF or presence of HF.	B
	In all patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and cardiovascular events.	A
	Blood pressure should be controlled in accordance with clinical practice guidelines for hypertension to prevent symptomatic HF.	A
	ACE inhibitors should be used in all patients with a reduced EF to prevent symptomatic HF.	A
	Beta blockers should be used in all patients with a reduced EF to prevent symptomatic HF.	C
IIa	To prevent sudden death, placement of an ICD is reasonable in patients with asymptomatic ischemic cardiomyopathy who are at least 40 days post-MI, have an LVEF of 30% or less, are on appropriate medical therapy, and have reasonable expectation of survival with a good functional status for more than 1 yr.	B
III: Harm	Nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful in asymptomatic patients with low LVEF and no symptoms of HF after MI.	B

ACC, American College of Cardiology; *ACE,* angiotensin-converting enzyme; *ACS,* acute coronary syndrome; *AHA,* American Heart Association; *ARB,* angiotensin receptor antagonist; *EF,* ejection fraction; *HF,* heart failure; *ICD,* implantable cardioverter-defibrillator; *LVEF,* left ventricular ejection fraction; *MI,* myocardial infarction.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

HF but should be discontinued in patients with hypotension or those requiring inotropic support. Beta-blockers should not be initiated in patients who are not on chronic beta-blocker therapy until euvolemia is achieved unless used for rate control.

- Morphine sulfate can cause venodilation and thus reduce cardiac preload. It may be used to reduce patient work of breathing and anxiety, but recent retrospective studies have suggested increased incidence of mechanical ventilation and in-hospital mortality in patients who received morphine.
- If ADHF with preserved EF is suspected, therapy is usually aimed at relief of symptoms and correction of any potential precipitating etiologies (e.g., tachycardia, hypertension, ischemia). Treatment generally involves diuretics to reduce pulmonary congestion with caution to not overdiurese given the need for elevated filling pressures in these patients to ensure adequate stroke volume and cardiac output. Nitrates may be useful in providing symptomatic relief but may precipitate hypotension. Ventricular rate should be controlled in the presence of atrial fibrillation, which, at rapid rates, is poorly tolerated in patients with impaired diastolic filling. Negative inotropic agents such as beta-blockers and calcium channel blockers can be used with caution. ACC/AHA/HSFA guidelines for treatment of patients with stage C HF and preserved left ventricular ejection fraction are summarized in Table 15.
- Nesiritide (recombinant brain natriuretic protein) does not reduce morbidity or mortality (ASCEND-HF trial).
- 2nd phase: Inpatient hospital care.
  1. This phase of treatment includes further diuresis and stabilization of volume status (Table 16). The patient should be carefully brought to euvolemia with daily volume status and electrolyte monitoring. The patient should also be transitioned to oral diuretics when stabilized. While inpatient, the patient should have his/her medical and device management optimized with the therapies discussed later.
- 3rd phase: Early discharge planning and care.
  1. The patient should be transitioned to oral diuretics and be placed on optimum outpatient maintenance therapy. If the patient was on IV inotropic therapy, oral regimens should be adjusted while these infusions are tapered off. Prolonged physiologic effects of these IV inotropic agents after their discontinuation before discharge may mask the inadequate diuretic regimen and intolerance to the vasodilator doses. This can result in readmission, especially with milrinone due to its long half-life that can be further prolonged by the common coexisting impaired renal function. Therefore it may be recommended that patients who received inotropic infusions remain hospitalized for at least 48 hours after inotropic agents are discontinued and optimize the oral regimen.
- 4th phase: Early postdischarge care
  1. The patient will require reevaluation and constant monitoring in order to avoid another episode of ADHF. Emphasis should be placed on importance of compliance with instructions regarding dietary restrictions and daily body weight monitoring. Early follow-up should be scheduled as well as outpatient electrolyte monitoring if required after medication adjustments.

CHRONIC TREATMENT OF HFREF: The goals of HF therapy are clinical improvement followed by stabilizing, slowing, or even reversing deterioration in myocardial function, and ultimately a reduction in risk of morbidity (including hospitalization rates) and mortality.

- ACE inhibitors:
  1. Reduce morbidity and mortality.
  2. Produce both venous and arterial vasodilation acutely, thereby reducing both preload and afterload.
  3. Potential mechanism of long-term benefit is attenuation of RAAS activation and decreased myocardial remodeling and fibrosis.

TABLE 12 ACC/AHA Guidelines for Treatment of Symptomatic Left Ventricular Systolic Dysfunction (Stage C)

Class	Indication	Level of Evidence
	Nonpharmacologic Interventions	
I	Patients with HF should receive specific education to facilitate HF self-care.	B
	Exercise training (or regular physical activity) is recommended as safe and effective for patients with HF who are able to participate to improve functional status.	A
IIa	Cardiac rehabilitation can be useful in clinically stable patients with HF to improve functional capacity, exercise duration, HRQOL, and mortality.	B
	Sodium restriction is reasonable for patients with symptomatic HF to reduce congestive symptoms.	C
	Continuous positive airway pressure (CPAP) can be beneficial to increase LVEF and improve functional status in patients with HF and sleep apnea.	B
	Pharmacologic Interventions	
I	Measures listed as class I recommendations for patients in stages A and B are recommended where appropriate.	A, B, C
	GDMT should be the mainstay of pharmacologic therapy for HFrEF.	A
	Diuretics	
I	Diuretics are recommended in patients with HFrEF who have evidence of fluid retention, unless contraindicated, to ameliorate symptoms.	C
	Angiotensin-Converting Enzyme Inhibitors/Adrenergic Receptor Blockers	
I	ACE inhibitors are recommended in patients with HFrEF and current or previous symptoms, unless contraindicated, to reduce morbidity and mortality.	A
	ARBs are recommended in patients with HFrEF with current or previous symptoms who are ACE inhibitor–intolerant, unless contraindicated, to reduce morbidity and mortality.	A
IIa	ARBs are a reasonable choice to reduce morbidity and mortality as alternatives to ACE inhibitors for first-line therapy in patients with HFrEF, especially in those already taking ARBs for other indications, unless contraindicated.	A
IIb	Addition of an ARB may be considered in persistently symptomatic patients with HFrEF who are already being treated with an ACE inhibitor and a beta-blocker in whom an aldosterone antagonist is not indicated or tolerated.	A
III: Harm	Routinely combining an ACE inhibitor, an ARB, and an aldosterone antagonist.	C
	Beta-Blockers	
I	Use of one of the three beta-blockers proven to reduce mortality (i.e., bisoprolol, carvedilol, and sustained-release metoprolol succinate) is recommended for all patients with current or previous symptoms of HFrEF, unless contraindicated, to reduce morbidity and mortality.	A
	Aldosterone Receptor Antagonists	
I	Aldosterone receptor antagonists (or mineralocorticoid receptor antagonists) are recommended in patients with NYHA class II-IV and LVEF of ≤35%, unless contraindicated, to reduce morbidity and mortality.	A
I	Aldosterone receptor antagonists are recommended to reduce morbidity and mortality after an acute MI in patients with LVEF of ≤40% who develop symptoms of HF or who have a history of diabetes mellitus, unless contraindicated.	B
III: Harm	Inappropriate use of aldosterone receptor antagonists is potentially harmful because of life-threatening hyperkalemia or renal insufficiency when serum creatinine is >2.5 mg/dl in men or >2.0 mg/dl in women (or estimated glomerular filtration rate <30 ml/min/1.73 m^2), and/or potassium >5.0 mEq/liter.	B
	Hydralazine and Isosorbide Dinitrate	
I	The combination of hydralazine and isosorbide dinitrate is recommended to reduce morbidity and mortality for patients self-described as African Americans with NYHA class III-IV HFrEF receiving optimal therapy with ACE inhibitors and beta-blockers, unless contraindicated.	A
IIa	A combination of hydralazine and isosorbide dinitrate can be useful to reduce morbidity or mortality in patients with current or previous symptomatic HFrEF who cannot be given an ACE inhibitor or ARB because of drug intolerance, hypotension, or renal insufficiency, unless contraindicated.	B
	Digoxin	
IIa	Digoxin can be beneficial in patients with HFrEF, unless contraindicated, to decrease hospitalizations for HF.	B
	Anticoagulation	
I	Patients with chronic HF with permanent/persistent/paroxysmal atrial fibrillation and an additional risk factor for cardioembolic stroke (history of hypertension, diabetes mellitus, previous stroke or transient ischemic attack, or ≥75 yr of age) should receive chronic anticoagulant therapy.	A
I	The selection of an anticoagulant agent (warfarin, dabigatran, apixaban, or rivaroxaban) for permanent/persistent/paroxysmal atrial fibrillation should be individualized on the basis of risk factors, cost, tolerability, patient preference, potential for drug interactions, and other clinical characteristics, including time in the international normalized ratio therapeutic range if the patient has been taking warfarin.	C
IIa	Chronic anticoagulation is reasonable for patients with chronic HF who have permanent/persistent/paroxysmal atrial fibrillation but no additional risk factor for cardioembolic stroke.	B
III: No benefit	Anticoagulation is not recommended in patients with chronic HFrEF without atrial fibrillation, a previous thromboembolic event, or a cardioembolic source.	B
	Statins	
III: No benefit	Statins are not beneficial as adjunctive therapy when prescribed solely for HF.	A
	Omega-3 Fatty Acids	
IIa	Omega-3 PUFA supplementation is reasonable to use as adjunctive therapy in patients with NYHA class II-IV symptoms and HFrEF or HFpEF, unless contraindicated, to reduce mortality and cardiovascular hospitalizations.	B

Continued

TABLE 12 ACC/AHA Guidelines for Treatment of Symptomatic Left Ventricular Systolic Dysfunction (Stage C)—cont'd

Class	Indication	Level of Evidence
	Drugs of Unproven Value or That May Cause Harm	
III: No benefit	Nutritional supplements as treatment for HF are not recommended in patients with current or previous symptoms of HFrEF.	B
	Hormonal therapies other than to correct deficiencies are not recommended for patients with current or previous symptoms of HFrEF.	C
III: Harm	Drugs known to adversely affect the clinical status of patients with current or previous symptoms of HFrEF are potentially harmful and should be avoided or withdrawn whenever possible (e.g., most antiarrhythmic drugs, most calcium channel blocking drugs [except amlodipine], NSAIDs, or thiazolidinediones).	B
	Long-term use of infused positive inotropic drugs is potentially harmful for patients with HFrEF, except as palliation for patients with end-stage disease who cannot be stabilized with standard medical treatment (see recommendations for stage D).	C
	Calcium Channel Blockers	
III: No benefit	Calcium channel blocking drugs are not recommended for routine therapy in patients with HFrEF.	A

ACC, American College of Cardiology; *ACE,* angiotensin-converting-enzyme; *AHA,* American Heart Association; *ARB,* angiotensin-receptor blocker; *GDMT,* guideline-directed medical therapy; *HF,* heart failure; *HFpEF,* heart failure with preserved ejection fraction; *HFrEF,* heart failure with reduced ejection fraction; *HRQOL*, health-related quality of life; *LVEF,* left ventricular ejection fraction; *MI,* myocardial infarction; *NYHA,* New York Heart Association; *NSAID,* nonsteroidal antiinflammatory drug; *PUFA,* polyunsaturated fatty acid.

TABLE 13 ACC/AHA Recommendations for the Hospitalized Patient with Heart Failure (HF)

Class	Indication	Level of Evidence*
I	Thorough history and physical examination to evaluate for adequacy of systemic perfusion, volume status, contribution of precipitating factors and/or comorbidities, and whether HF is associated with preserved ejection fraction.	C
	Concentrations of B-type natriuretic peptide (BNP) or N-terminal pro-B-type natriuretic peptide (NT-proBNP) to evaluate dyspnea if the contribution of heart failure is not known.	A
	Acute coronary syndrome should be promptly identified by electrocardiogram and cardiac troponin testing, and treated, as appropriate to the overall condition and prognosis of patient.	C
	Oxygen therapy should be administered to relieve symptoms related to hypoxemia.	C
	Improve systemic perfusion in patients who present with rapid decompensation and hypoperfusion associated with decreasing urine output and other manifestations of shock.	C
	Treatment of significant fluid overload with intravenous loop diuretics. The diuretic dose should be titrated to relieve symptoms and to reduce extracellular fluid volume excess.	B, C
	Monitor the effects of therapy with careful measurement of fluid intake and output; vital signs; body weight, and symptoms of systemic perfusion and congestion.	C
	Intensify the diuretic regiment when the diuresis is inadequate to relieve congestion.	C
	Intravenous inotropic or vasopressor drugs should be administered to maintain systemic perfusion and preserve end-organ performance in patients with clinical evidence of hypotension associated with hypoperfusion and elevated cardiac filling pressures.	C
	Invasive hemodynamic monitoring to guide therapy in patients who are in respiratory distress or with clinical evidence of impaired perfusion if filling pressures cannot be determined from clinical assessment.	C
	Medications should be reconciled and adjusted as appropriate on admission to and discharge from the hospital.	C
	Maintenance treatment with oral therapies known to improve outcomes (ACE inhibitors or ARBs and beta-blocker therapy) in the absence of hemodynamic instability or contraindications.	C
	Initiation of treatment with oral therapies known to improve outcomes (ACE inhibitors or ARBs and beta-blocker therapy) in stable patients prior to hospital discharge.	B
	During transition from intravenous to oral diuretic therapy, patient should be monitored carefully for supine and upright hypotension, worsening renal function, and HF signs/symptoms.	C
	Comprehensive written discharge instructions for patients and their caregivers is strongly recommended.	C
	Postdischarge systems of care, if available, should be used to facilitate the transition to effective outpatient care.	B
IIa	Urgent cardiac catheterization and revascularization in patients with acute HF with known or suspected acute myocardial ischemia due to occlusive coronary disease when there are signs and symptoms of inadequate systemic perfusion and revascularization is likely to prolong meaningful survival.	C
	Intravenous nitroglycerin, nitroprusside, or nesiritide for patients with evidence of severely symptomatic fluid overload in the absence of systemic hypotension.	C
	Ultrafiltration for patients with refractory congestion not responding to medical therapy.	B
IIb	Intravenous inotropic drugs (dopamine, dobutamine, or milrinone) for patients presenting with documented severe systolic dysfunction, low blood pressure, and evidence of low cardiac output, with or without congestion, to maintain systemic perfusion and preserve end-organ performance.	C
III	Use of parenteral inotropes in normotensive patients with acute decompensated HF without evidence of decreased organ perfusion.	B
	Routine use of invasive hemodynamic monitoring in normotensive patients with acute decompensated HF and congestion with symptomatic response to diuretics and vasodilators.	B

*See guidelines text for definition of level of evidence categories.
ACC, American College of Cardiology; *ACE,* angiotensin-converting enzyme; *AHA,* American Heart Association; *ARB,* angiotensin-receptor blocker.

TABLE 14 Intravenous Vasoactive Agents for Treatment of Acute Heart Failure

Intravenous Medication	Initial Dose	Effective Dose Range	Comments
Vasodilators			
Nitroglycerin; glyceryl trinitrate	20 μg/min	40-400 μg/min	Hypotension, headache Tolerance with continuous use after 24 hours
Isosorbide dinitrate	1 mg/hr	2-10 mg/hr	Hypotension, headache Tolerance with continuous use within 24 hours
Nitroprusside	0.3 μg/kg/min	0.3-5 μg/kg/min (usually <4 μg/kg/min)	Caution in patients with active myocardial ischemia Hypotension; cyanide side effects (nausea, dysphoria); thiocyanate toxicity; light sensitive
Nesiritide	2 μg/kg bolus with 0.010-0.030 μg/kg/min infusion*	0.010-0.030 μg/kg/min†	Uptitration: 1 μg/kg bolus, then increase infusion rate by 0.005 μg/kg/min no more frequently than every 3 hours, up to maximum of 0.03 μg/kg/min Hypotension, headache (less than with organic nitrates)
Inotropes			
Dobutamine	1-2 μg/kg/min	2-20 μg/kg/min	For inotropy and vasodilation; hypotension, tachycardia, arrhythmias; ?mortality
Dopamine	1-2 μg/kg/min	2-4 μg/kg/min	For inotropy and vasodilation; hypotension, tachycardia, arrhythmias; ?mortality
	4-5 μg/kg/min	5-20 μg/kg/min	For inotropy and vasoconstriction; tachycardia, arrhythmias; ?mortality
Milrinone	25-75 μg/kg bolus over 10-20 min* followed by infusion	0.10-0.75 μg/kg/min	For vasodilation and inotropy; hypotension, tachycardia, arrhythmias; renal excretion; ?mortality
Enoximone††	0.25-0.75 mg/kg	1.25-7.5 μg/kg/min	For vasodilation and inotropy; hypotension, tachycardia, arrhythmias; ?mortality
Levosimendan††	12-24 μg/kg bolus over 10 min followed by infusion	0.5-2.0 μg/kg/min	For vasodilation and inotropy; active metabolite present for ~84 hours; hypotension, tachycardia, arrhythmias; ?mortality
Epinephrine		0.05-0.5 μg/kg/min	For vasoconstriction and inotropy; tachycardia, arrhythmias, end-organ hypoperfusion; ?mortality
Norepinephrine		0.2-1.0 μg/kg/min	For vasoconstriction and inotropy; tachycardia, arrhythmias, end-organ hypoperfusion; ?mortality

*Some clinicians do not administer a bolus dose to decrease the risk of hypotension. Bolus not recommended in patients with hypotension.
†Lower doses have also been effective in some small studies.
††Not approved for use in all countries.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 15 ACC/AHA/HFSA Guidelines for Treatment of Patients with Stage C Heart Failure and Preserved Left Ventricular Ejection Fraction (HFpEF)

Class	Indication	Level of Evidence
I	Systolic and diastolic blood pressure should be controlled in accordance with published clinical practice guidelines to prevent morbidity.	B
	Diuretics should be used for relief of symptoms due to volume overload.	C
IIa	Coronary revascularization is reasonable in patients with coronary artery disease in whom symptoms (angina) or demonstrable myocardial ischemia is judged to be having an adverse effect on symptomatic heart failure.	C
	Management of atrial fibrillation according to published clinical practice guidelines is reasonable to improve symptomatic heart failure.	C
	The use of beta-blocking agents, ACE inhibitors, and ARBs in patients with hypertension is reasonable to control blood pressure.	C
IIb	In appropriately selected patients with HFpEF (with EF ≥45%, elevated BNP levels or heart failure admission within 1 yr, estimated glomerular filtration rate >30 ml/min, creatinine <2.5 mg/dL, potassium <5.0 mEq/L), aldosterone receptor antagonists might be considered to decrease hospitalizations.	B-R
IIb	The use of ARBs might be considered to decrease hospitalizations.	B
III: No benefit	The routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is ineffective.	B-R
III: No benefit	Routine use of nutritional supplements is not recommended.	C

ACC, American College of Cardiology; *ACE,* angiotensin-converting enzyme; *AHA,* American Heart Association; *ARB,* angiotensin receptor blocker; *BNP,* B-type (brain) natriuretic peptide; *HFSA,* Heart Failure Society of America. From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

4. Used as first-line therapy for asymptomatic LV dysfunction (LVEF <40%) and symptomatic systolic HF (ACC/AHA grades A-D).
5. Therapy should be initiated at low doses to prevent hypotension and rapidly titrated to higher doses as tolerated.
6. Contraindications to the use of ACE inhibitors are renal insufficiency (creatinine clearance <30 ml/min), bilateral renal artery stenosis, hyperkalemia, hypotension, or adverse reactions (e.g., angioedema).

- ARBs:
  1. Receptor antagonists to the angiotensin II receptor.
  2. Clinical trials have not shown any superiority compared to ACE inhibitors in patients with systolic HF (LVEF <40%).
  3. Reserved for patients who are ACE inhibitor intolerant.
  4. Combination therapy with ARBs and ACE inhibitors is generally not recommended.
  5. Have a similar contraindication profile to ACE inhibitors. Routine combined use of an ACE inhibitor, ARB, and aldosterone antagonist is potentially harmful for patients with HFrEF.

TABLE 16 Therapeutic Approaches for Volume Management in Acute Heart Failure (AHF)

Severity of Volume Overload	Diuretic	DOSE (mg)	Comments
Moderate	Furosemide, or	20-40, or up to 2.5 times oral dose	IV administration preferable in symptomatic patients
	Bumetanide, or	0.5-1.0	Titrate dose according to clinical response.
	Torsemide	10-20	Monitor Na^+, K^+, creatinine, BP
Severe	Furosemide, or	40-160, or 2.5 times oral dose 5-40 mg/hr infusion	Intravenously
	Bumetanide, or	1-4/0.5-2 mg/hr infusion (max, 2-4 mg/hr, limit 2-4 hr)	Bumetanide and torsemide have higher oral bioavailability than furosemide, but IV administration preferable in AHF.
	Torsemide	20-100/5-20 mg/hr	
	Ultrafiltration	200-500 ml/hr	Adjust ultrafiltration rate to clinical response; monitor for hypotension; consider hematocrit sensor.
Refractory to loop diuretics	Add HCTZ, *or*	25-50 twice daily	Combination with loop diuretic may be better than very high dose of loop diuretics alone.
	Metolazone, *or*	2.5-10 once daily	Metolazone more potent if creatinine clearance <30 ml/min
	Chlorothiazide, *or*	250-500 mg IV 500-1000 mg PO	
	Spironolactone	25-50 once daily	Spironolactone best choice if patient not in renal failure and normal or low serum K^+, although may not be very potent
In case of alkalosis	Acetazolamide	0.5	Intravenously
Refractory to loop diuretics and thiazides	Add dopamine (renal vasodilation), *or* dobutamine or milrinone (inotropic agent)		
	Ultrafiltration, or hemodialysis if coexisting renal failure		

BP, Blood pressure; *IV,* intravenous; *HCTZ,* hydrochlorothiazide; *PO,* by mouth.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

- Angiotensin receptor–neprilysin inhibitor (ARNI) (valsartan/sacubitril):
  1. Neprilysin is an enzyme that degrades natriuretic peptides, bradykinin, adrenomedullin, and other vasoactive peptides.
  2. In a randomized controlled trial (PARADIGM-HF) that compared valsartan/sacubitril with enalapril in symptomatic patients with HFrEF tolerating an adequate dose of either ACE inhibitor or ARB, the ARNI reduced the composite end point of cardiovascular death or HF hospitalization significantly, by 20%. Additionally, in another randomized controlled trial (PIONEER – HF), in HFrEF patients hospitalized with decompensated HF, initiation of valsartan/sacubitril caused a greater reduction in NT-proBNP concentration than enalapril. Rates of adverse effects did not significantly differ between the two groups.
  3. In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality (class I).
  4. ARNI should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor (class III: Harm).
  5. ARNI should not be administered to patients with a history of angioedema (class III: Harm).
  6. ARNI has not shown additional benefit over ARB in patients with preserved ejection fraction and is not indicated in this group of patients.
- Beta-adrenergic blockers (beta-blockers):
  1. Reduce morbidity and mortality. Such benefits observed with bisoprolol (CIBIS II trial), metoprolol succinate (MERIT-HF trial), and carvedilol (COPERNICUS trial).
  2. Benefit is believed to be conferred by blockade of sympathetic effects of neurohormonal stimulation due to HF.
  3. Are considered first-line therapy for symptomatic patients with systolic HF (NYHA class ≥II and LVEF <35%).
  4. Only carvedilol, bisoprolol, and metoprolol succinate (long acting) have been approved for the medical treatment of chronic HF; these agents are generally started in patients judged to be euvolemic and dosage is to be slowly uptitrated as tolerated.
  5. Adverse effects include worsening HF (due to negative inotropic effects), fatigue, dizziness, bradycardia, hypotension, and bronchospasm.
- Aldosterone receptor antagonists:
  1. Reduce morbidity and mortality.
  2. Indicated in patients with NYHA class II-IV HF, with LVEF ≤35%, already treated with ACE inhibitors and beta-blockers without significant renal insufficiency or hyperkalemia. Patients with NYHA class II should have a history of prior cardiovascular hospitalization or elevated plasma natriuretic peptide levels to be considered for aldosterone receptor antagonists. Creatinine should be ≤2.5 mg/dl in men or ≤2.0 mg/dl in women (or estimated glomerular filtration rate >30 ml/min/1.73 m2), and potassium should be <5.0 mEq/L. They are also indicated for post-MI patients with EF ≤40% who have either symptomatic HF or diabetes mellitus.
  3. Spironolactone may cause gynecomastia, galactorrhea, and hyperkalemia (especially in patients with baseline renal insufficiency or type 4 renal tubular acidosis). It has been best studied in chronic HF with NYHA class III to IV symptoms (RALES study).
  4. Eplerenone is associated with fewer endocrine side effects and has especially been studied in postmyocardial infarction left ventricular dysfunction (EPHESUS trial) and in chronic systolic HF with only class II symptoms (EMPHASIS-HF trial).
  5. Inappropriate use of aldosterone receptor antagonists is potentially harmful because of life-threatening hyperkalemia or renal insufficiency when serum creatinine is >2.5 mg/dl in men or >2.0 mg/dl in women (or estimated glomerular filtration rate <30 ml/min/1.73 m2), and/or potassium >5.0 mEq/L.
- Diuretics:
  1. They are used to maintain euvolemia and to improve symptoms as discussed previously.
  2. Although data on diuretic efficacy are limited, a meta-analysis of a few small trials

found that they were associated with reduction in mortality as well as reduced hospitalization for HF.
3. Of note, loop diuretics with better bioavailability, such as torsemide and bumetanide, may be used in diuretic-resistant patients but are generally more expensive.

- Combination of isosorbide dinitrate and hydralazine:
  1. Cause venous (nitrates) and arteriolar (hydralazine) vasodilation resulting in decreased preload and afterload.
  2. The combination of hydralazine and isosorbide dinitrate is recommended to reduce morbidity and mortality for patients self-described as African Americans with NYHA class III–IV HFrEF receiving optimal therapy with ACE inhibitors and beta-blockers, unless contraindicated.
  3. A combination of hydralazine and isosorbide dinitrate can be useful to reduce morbidity or mortality in patients with current or prior symptomatic HFrEF who cannot be given an ACE inhibitor or ARB because of drug intolerance, hypotension, or renal insufficiency, unless contraindicated.
  4. Adverse effects of nitrates include hypotension, headaches, and tolerance as well as reflex tachycardia and lupus-like syndrome with hydralazine.
- Digoxin:
  1. Positive inotropic and negative chronotropic drug that works by inhibition of the sodium-potassium transmembrane exchange pump and through its vagomimetic action.
  2. Commonly used in patients with concomitant atrial fibrillation.
  3. Has been shown to reduce HF-related hospitalizations but does not confer any mortality benefit (DIG trial). However, there is evidence suggesting that digoxin may actually have an effect on survival that varies with the serum digoxin level; survival was improved when the level was between 0.5 and 0.8 ng/ml (most often in men) and significantly worsened when it was ≥1.2 ng/ml and >0.9 mg/ml in women.
  4. Caution must be used in patients with abnormal renal function to avoid digoxin toxicity and life-threatening arrhythmia. Avoid hypokalemia because potassium competes with digoxin on the same site of the Na^+-K^+-ATPase pump.
- I_f channel inhibitor (ivabradine):
  1. Ivabradine is a new therapeutic agent that selectively inhibits the I_f current in the sinoatrial node, providing heart rate reduction.
  2. Ivabradine can be beneficial to reduce HF hospitalization for patients with symptomatic (NYHA class II-III) stable chronic HFrEF (LVEF ≤35%) who are receiving guideline-directed therapy, including a beta-blocker at maximum tolerated dose, and who are in sinus rhythm with a heart rate of 70 bpm or greater at rest (class IIa).
- Cardiac resynchronization therapy (CRT):
  1. Improves morbidity and mortality rates in selected patients.
  2. The presence of a bundle-branch block or other intraventricular conduction delay (IVCD) can cause ventricular dyssynchrony, which induces regional loading disparities and reduces the efficiency of ventricular contraction, thereby further impairing the systolic function of a failing ventricle.
  3. CRT is indicated for patients who have LVEF ≤35%, sinus rhythm, left bundle-branch block with a QRS duration of 150 ms or greater, and NYHA class II, III, or ambulatory IV symptoms on guideline-directed medical therapy. CRT is NOT indicated in patients whose functional status and life expectancy are limited predominantly by chronic noncardiac conditions. Life expectancy should be >1 yr.
  4. In the appropriate subset of patients, CRT in addition to optimal medical therapy has been shown in numerous clinical trials to improve symptoms by at least one NYHA class, improve 6-min walk distance and quality of life, reduce rate of HF-related hospitalization, and reduce rate of all-cause and cardiovascular mortality.
  5. ACC/AHA guidelines for cardiac resynchronization therapy are summarized in Table 17.
- Implantable cardioverter-defibrillators (ICDs):
  1. Sudden cardiac death (SCD) is a common cause of death in patients with HF in both ischemic and nonischemic cardiomyopathies. Ventricular tachycardia (VT) degenerating into ventricular fibrillation (VF) is the culprit in the majority of patients with SCD, although bradyarrhythmias do also occur with less frequency.
  2. ICD therapy is recommended for primary prevention of SCD to reduce total mortality in selected patients with nonischemic dilated cardiomyopathy or ischemic heart disease at least 40 days post-MI with LVEF ≤35% and NYHA class II or III symptoms on chronic guideline-directed medical therapy, who have reasonable expectation of meaningful survival for >1 yr.
  3. Patients with HF who survive an episode of sudden cardiac arrest or experience sustained VT in the presence of

TABLE 17 ACCF/AHA Guidelines for Cardiac Resynchronization Therapy (CRT)

Class	Indication	Level of Evidence
I	CRT is indicated for patients who have LVEF of 35% or less, sinus rhythm, LBBB with QRS duration of 150 msec or greater, and NYHA Class II, III, or ambulatory IV symptoms on GDMT.	A for NYHA Class III/I B for Class II
IIa	CRT can be useful for patients who have LVEF of 35% or less, sinus rhythm, non-LBBB pattern with QRS duration of 150 msec or greater, and NYHA Class III/ambulatory Class IV symptoms on GDMT.	A
	CRT can be useful for patients who have LVEF of 35% or less, sinus rhythm, LBBB with QRS duration of 120 to 149 msec, and NYHA Class II, III, or ambulatory IV symptoms on GDMT.	B
	CRT can be useful in patients with atrial fibrillation and LVEF of 35% or less on GDMT if (a) the patient requires ventricular pacing or otherwise meets CRT criteria and (b) atrioventricular nodal ablation or pharmacologic rate control will allow near-100% ventricular pacing with CRT.	B
	CRT can be useful for patients on GDMT who have LVEF of 35% or less and are undergoing placement of new or replacement device with anticipated requirement for significant (>40%) ventricular pacing.	C
IIb	CRT may be considered for patients who have LVEF of 35% or less, sinus rhythm, non-LBBB pattern with QRS duration of 120 to 149 msec, and NYHA Class III/ambulatory Class IV on GDMT.	B
	CRT may be considered for patients who have LVEF of 35% or less, sinus rhythm, non-LBBB pattern with QRS duration of 150 msec or greater, and NYHA Class II symptoms on GDMT.	B
	CRT may be considered for patients who have LVEF of 30% or less, ischemic etiology of HF, sinus rhythm, LBBB with QRS duration of 150 msec or greater, and NYHA Class I symptoms on GDMT.	C
III: No benefit	CRT is not recommended for patients with NYHA Class I or II symptoms and non-LBBB pattern with QRS duration less than 150 msec.	
	CRT is not indicated for patients whose comorbidities and/or frailty limit survival with good functional capacity to less than 1 yr.	

ACCF, The American College of Cardiology Foundation; *AHA,* American Heart Association; *GDMT,* guideline-directed medical therapy; *LBBB,* left bundle-branch block; *LVEF,* left ventricular ejection fraction; *NYHA,* New York Heart Association.

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

LVEF <35% are at high risk for future arrhythmic events and SCD and obtain a mortality benefit from ICD placement for secondary prevention, with or without adjunctive therapies such as antiarrhythmic drugs, radiofrequency ablation, surgery, or transplant.

4. ACC/AHA guidelines for indications for implantable cardioverter-defibrillators are summarized in Table 18.

- In the absence of an indication (e.g., atrial fibrillation), routine use of anticoagulation is currently not recommended in patients with HF. Even with the increased risk for LV thrombus formation in dilated cardiomyopathy and subsequent thromboembolization, data are conflicting about benefits of antithrombotic (antiplatelet or anticoagulant) therapy for primary prevention to reduce thromboembolic events or mortality in patients with systolic HF who are in sinus rhythm (SOLVD, V-HeFT, SAVE, HELAS, and WASH trials). It may be reasonable to consider anticoagulation for secondary prevention in patients with HF who had a prior thromboembolic event; however, risks and benefits should be carefully assessed.
- Antiplatelet agents are recommended for patients with concomitant CAD.
- Statins are not beneficial as adjunctive therapy when prescribed solely for the diagnosis of HF in the absence of other indications for their use.
- Calcium channel blocking drugs are not recommended as routine treatment for patients with HFrEF.
- Omega-3 polyunsaturated fatty acid supplementation is reasonable to use as adjunctive therapy in patients with NYHA class II-IV symptoms and HFrEF or HFpEF, unless contraindicated, to reduce mortality and cardiovascular hospitalizations.
- Percutaneous coronary intervention (PCI) or surgical revascularization should be considered in patients with HF and significant CAD who are revascularization candidates.
- In general, the following sequence of drugs is recommended:
  1. Loop diuretics to provide symptom relief and achieve a euvolemic state.
  2. ACE inhibitor or ARB started at low doses, then increased to a moderate dose in 1-2 wk. Replace with ARNI in those tolerating ACE inhibitor or ARB.
  3. Beta-blockers after the patient is stable on ACE/ARB treatment. Start a low dose, then uptitrate to goal based on trial data or maximal dose tolerated. Once achieved, uptitration of ACE or ARB to goal doses can be completed.
- The following drugs can be added in selected patients in the absence of contraindications:
  1. Aldosterone antagonists improve survival in NYHA class II with LVEF <30% or NYHA class III-IV with EF <35%. Kidney function should be stable with eGFR ≥30 ml/min and potassium <5 mEq/L.
  2. Combination of hydralazine with a nitrate in patients (particularly African Americans) with a reduced EF.
  3. Digoxin reduces hospitalizations for HF and controls HR in atrial fibrillation. It can also help control symptoms.

CHRONIC TREATMENT OF HFPEF:

- To date, there is a relative dearth of clinical trials examining effective chronic treatment strategies in this subset of patients with HFpEF. Current therapies are mainly for symptomatic relief. ACC/AHA guidelines for treatment of patients with end-stage heart failure are summarized in Table 19.
- Therapy centers on relief of volume overload with judicious diuretic use, treatment of ischemia via coronary revascularization (Table 20), management of atrial fibrillation, controlling heart rate and blood pressure to prevent acute decompensation, and restriction of sodium and fluid to prevent volume overload.
- Diuretics should be used for relief of symptoms due to volume overload in patients with HFpEF.
- The use of beta-blocking agents, ACE inhibitors, and ARBs in patients with hypertension is reasonable to control blood pressure in patients with HFpEF.
- The use of ARBs might be considered to decrease hospitalizations for patients with HFpEF.
- Aldosterone antagonists may be used in appropriate patients with HFpEF (EF >45%, elevated BNP or HF admission in the past yr, potassium <5.0 mEq/L, estimated glomerular filtration rate >30 and creatinine <2.5 mg/dl) to decrease hospitalizations (class IIb recommendation).
- Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or quality of life in patients with HFpEF is not recommended as there is no benefit.
- There is no evidence to support routine use of nutritional supplements, and they are not recommended for patients with HFpEF.
- Surgical options (Table 21) for contributing critical aortic stenosis, constrictive pericarditis, and hypertrophic cardiomyopathy (HCM) should be entertained in appropriate patients.
- In patients with comorbidities including anemia, hypertension, and sleep apnea, the following recommendations are made:
  1. Intravenous iron replacement in patients with NYHA class II and III HF and iron deficiency (ferritin <100 ng/ml or 100-300 ng/ml with transferrin saturation <20%) to improve functional status and quality of life (class IIb recommendation).
  2. Titration of medical therapy to attain systolic blood pressure <130 mm Hg is recommended in patients with HFrEF and hypertension, as well as in patients with HFpEF and persistent hypertension after treatment of volume overload (class I recommendation).
  3. A formal sleep assessment should be obtained in patients with NYHA class II-IV HF with suspicion of sleep-disordered breathing. Continuous positive airway pressure should be used in patients with HF and obstructive sleep apnea to improve sleep quality and daytime sleepiness (class IIb recommendation).

DISPOSITION

- Coordination of care (Table 22) is essential in patients with chronic heart failure.
- Annual mortality of systolic HF ranges from 10% in stable patients with mild symptoms to 50% in patients with NYHA class IV disease (a mortality rate rivaling some malignancies).

TABLE 18 ACCF/AHA Guidelines for Indications for Implantable Cardioverter-Defibrillators (ICDs)

Class	Indication	Level of Evidence
I	ICD therapy is recommended for primary prevention of SCD in selected patients with HFrEF at least 40 days post-MI with LVEF less than 35% and NYHA Class II or III symptoms receiving chronic GDMT, who are expected to live more than 1 yr.	A
I	ICD therapy is recommended for primary prevention of SCD in selected patients with HFrEF at least 40 days post-MI with LVEF less than 30% and NYHA Class I symptoms receiving GDMT, who are expected to live more than 1 yr.	B
IIa	To prevent SCD, placement of ICD is reasonable in patients with asymptomatic ischemic cardiomyopathy who are at least 40 days post-MI, have an LVEF of 30% or less, are on appropriate medical therapy, and have reasonable expectation of survival with a good functional status for more than 1 yr.	B
IIb	ICD therapy to prevent SCD in patients with nonischemic cardiomyopathy who are at least 40 days post-MI, have LVEF less than 35%, with NYHA Class II or III symptoms while undergoing chronic optimal medical therapy, and have reasonable expectation of survival for more than 1 yr with good functional status.	B
	Usefulness of implantation of ICD is of uncertain benefit to prolong meaningful survival in patients with high risk of non-SCD, as predicted by frequent hospitalizations, advanced frailty, or comorbidities such as systemic malignancy or severe renal dysfunction.	B

HFrEF, Heart failure with reduced ejection fraction; *MI,* myocardial infarction; *SCD,* sudden cardiac death; see **Table 17** for other abbreviations.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 19 ACC/AHA Guidelines for Treatment of Patients with End-Stage Heart Failure (Stage D)

Class	Indication	Level of Evidence
	Nonpharmacologic Interventions	
IIa	Fluid restriction (1.5-2 L/day) is reasonable in stage D, especially in patients with hyponatremia.	B
	Inotropic Support	
I	Until definitive therapy (e.g., coronary revascularization, MCS, heart transplantation) or resolution of the acute precipitating problem, patients with cardiogenic shock should receive temporary IV inotropic support to maintain systemic perfusion and preserve end-organ performance.	C
IIa	Continuous IV inotropic support is reasonable as "bridge therapy" in patients with stage D refractory to GDMT and device therapy who are eligible for and awaiting MCS or cardiac transplantation.	B
IIb	Short-term, continuous IV inotropic support may be reasonable in those hospitalized patients presenting with documented severe systolic dysfunction who present with low blood pressure and significantly depressed cardiac output, to maintain systemic perfusion and preserve end-organ performance.	B
	Long-term, continuous IV inotropic support may be considered as palliative therapy for symptom control in select patients with stage D despite optimal GDMT and device therapy who are not eligible for either MCS or cardiac transplantation.	B
III: Harm	Long-term use of either continuous or intermittent, IV parenteral positive inotropic agents, in the absence of specific indications or for reasons other than palliative care, is potentially harmful in the patient with HF.	B
	Use of parenteral inotropic agents in hospitalized patients without documented severe systolic dysfunction, low blood pressure, or impaired perfusion, and evidence of significantly depressed cardiac output, with or without congestion, is potentially harmful.	B
	Mechanical Circulatory Support (MCS)	
IIa	MCS is beneficial in carefully selected patients with stage D HFrEF in whom definitive management (e.g., cardiac transplantation) or cardiac recovery is anticipated or planned.	B
	Nondurable MCS, including the use of percutaneous and extracorporeal ventricular assist devices (VADs), is reasonable as a "bridge to recovery" or "bridge to decision" for carefully selected patients with HFrEF with acute, profound hemodynamic compromise.	B
	Durable MCS is reasonable to prolong survival for carefully selected patients with stage D HFrEF.	B
	Cardiac Transplantation	
I	Evaluation for cardiac transplantation is indicated for carefully selected patients with stage D HF despite GDMT, device, and surgical management	C

TABLE 20 ACC/AHA Guidelines for Surgical/Percutaneous/Transcatheter Interventional Treatments of Heart Failure

Class	Indication	Level of Evidence
I	Coronary artery revascularization via CABG or percutaneous intervention is indicated for patients (HFpEF and HFrEF) on GDMT with angina and suitable coronary artery anatomy, especially for a left main artery stenosis (>50%) or left main–equivalent disease.	C
IIa	CABG to improve survival is reasonable in patients with mild to moderate LV systolic dysfunction (EF 35%-50%) and significant (≥70% diameter stenosis) multivessel CAD or proximal left anterior descending coronary artery stenosis when viable myocardium is present in the region of intended revascularization.	B
	CABG or medical therapy is reasonable to improve morbidity and cardiovascular mortality for patients with severe LV dysfunction (EF <35%), HF, and significant CAD.	B
	Surgical aortic valve replacement is reasonable for patients with critical aortic stenosis and a predicted surgical mortality of no greater than 10%.	B
	Transcatheter aortic valve replacement after careful candidate consideration is reasonable for patients with critical aortic stenosis who are deemed inoperable.	B
IIb	CABG may be considered with the intent of improving survival in patients with ischemic heart disease with severe LV systolic dysfunction (EF <35%) and operable coronary anatomy whether or not viable myocardium is present.	B
	Transcatheter mitral valve repair or mitral valve surgery for functional mitral insufficiency is of uncertain benefit and should only be considered after careful candidate selection and with a background of GDMT.	B
	Surgical reverse remodeling or LV aneurysmectomy may be considered in carefully selected patients with HFrEF for specific indications, including intractable HF and ventricular arrhythmias.	B

The Seattle Heart Failure Model provides an accurate estimate of 1-, 2-, and 3-yr survival before and after different therapies. This model can be useful to assess the need for LV assist device implantation or urgent transplantation. The calculator is available online at http://depts.washington.edu/shfm/.

- Cardiac transplantation has a 5-yr survival rate of ~70% and represents a viable option in selected patients. Fig. E4 describes an algorithm for evaluation of potential heart transplant recipient.
- The use of an LV assist device (LVAD) in patients with advanced HF can result in a clinically meaningful survival benefit and improve quality of life in patients who are not candidates for cardiac transplantation. There are two approved uses of LVADs specifically as a bridge to transplant and as destination therapy. There are two major categories of LVAD pulsatile flow devices vs. continuous

TABLE 21 Surgery for Management of Heart Failure (HF): Guideline Recommendations

2016 ESC Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure

Recommendations for Myocardial Revascularization in Patients with Chronic HF

- Myocardial revascularization is recommended when angina persists despite antiangina drugs; *class I, level of evidence A.*
  The choice between CABG and PCI should be made by the heart team after careful review.
  CABG is recommended for patients with angina and significant LM or LM-equivalent stenosis to improve prognosis.
  CABG is recommended for patients with HFrEF, significant CAD (LAD or multivessel disease), and LVEF <35%.

2014 ACC/AHA/AATS/PCNA/SCAI/STS Focused Update of the Guideline for the Diagnosis and Management of Patients with Stable Ischemic Heart Disease*

- A heart team approach to revascularization is recommended in patients with diabetes mellitus and complex multivessel CAD; *class 1, level of evidence C.*
- CABG is generally recommended in preference to PCI to improve survival in patients with diabetes mellitus and multivessel CAD for which revascularization is likely to improve survival (3-vessel CAD or complex 2-vessel CAD involving the proximal LAD); *class 1, level of evidence B.*

2014 AHA/ACC Guideline for the Management of Patients with Valvular Heart Disease†

Indications for Aortic Valve Surgery in Aortic Stenosis (as) with Left Ventricular Dysfunction

- AVR is recommended for asymptomatic patients with severe AS and LVEF <50%; *class I, level of evidence B.*
- AVR is reasonable in symptomatic patients with low-flow/low-gradient severe AS with reduced LVEF with a low-dose dobutamine stress study that shows an aortic velocity ≥4.0 m/sec or mean pressure gradient ≥40 mm Hg with a valve area of ≤1.0 cm^2; *class IIa, level of evidence B.*
- AVR is reasonable for patients with moderate AS who are undergoing other cardiac surgery; *class IIa, level of evidence C.*
- TAVR is recommended in patients who meet an indication for AVR for AS and who have a prohibitive surgical risk and post-TAVR survival >12 mo; *class I, level of evidence B.*
- TAVR is a reasonable alternative to surgical AVR in patients who meet an indication for AVR and who have a high surgical risk; *class IIa, level of evidence B.*

Indications for Aortic Valve Surgery in Aortic Regurgitation (AR) with LV Dysfunction

- AVR is recommended for symptomatic patients with severe AR; *class I, level of evidence B.*
- AVR is indicated for patients with severe AR and LV systolic dysfunction; *class I, level of evidence B.*

Indications for Mitral Valve Surgery in Functional Mitral Regurgitation (MR)

- Mitral valve surgery is reasonable for patients with chronic severe functional MR who are undergoing CABG or AVR; *class IIa, level of evidence C.*
- Mitral valve surgery may be considered for severely symptomatic patients (NYHA Class III/IV) with chronic severe functional MR; *class IIb, level of evidence B.*
- Mitral valve repair may be considered for patients with chronic moderate functional MR who are undergoing other cardiac surgery; *class IIb, level of evidence C.*

ESC/EACTS Guidelines on the Management of Valvular Heart Disease (Version 2012)‡

Indications for Mitral Valve Surgery in Chronic Secondary Mitral Regurgitation (MR)

- Surgery is indicated in patients with severe MR undergoing CABG and LVEF >30%; *class I, level of evidence C.*
- Surgery should be considered in patients with moderate MR undergoing CABG; *class IIa, level of evidence C.*
- Surgery should be considered in symptomatic patients with severe MR, LVEF <30%, option for revascularization, and evidence of viability; *class IIa, level of evidence: C.*
- Surgery may be considered in patients with severe MR, LVEF >30%, who remain symptomatic despite optimal medical management (including CRT if indicated) and have low comorbidity, when revascularization is not indicated; *class IIb, level of evidence C.*

TABLE 22 Coordinating Care for Patients with Chronic Heart Failure

Class	Indication	Level of Evidence
I	Effective systems of care coordination with special attention to care transitions should be deployed for every patient with chronic HF that facilitate and ensure effective care that is designed to achieve GDMT and prevent hospitalization.	B
	Every patient with HF should have a clear, detailed, and evidence-based plan of care that ensures the achievement of GDMT goals, effective management of comorbid conditions, timely follow-up with the health care team, appropriate dietary and physical activities, and compliance with secondary prevention guidelines for cardiovascular disease. This plan of care should be updated regularly and made readily available to all members of the patient's health care team.	C
	Palliative and supportive care is effective for patients with symptomatic advanced HF to improve quality of life.	B

GDMT, Guideline directed medical therapy; *HF,* heart failure.

From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

flow devices. Continuous flow devices are associated with increased survival as destination therapy as compared to medically managed controls (REMATCH trial).

BASIC INFORMATION

DEFINITION

Heat exhaustion and heat stroke are part of a continuum of heat-related illness, and unless factors leading to heat exhaustion are corrected swiftly, affected patients can progress to heat stroke.

- ***Heat exhaustion:*** An illness resulting from prolonged, heavy activity in a hot environment with subsequent dehydration, electrolyte depletion, and rectal temperature >37.8° C (100° F) but ≤40° C (104° F).
- ***Heat stroke:*** A life-threatening heat illness characterized by extreme hyperthermia (core temperature >40° C [104.0° F]), dehydration, and neurologic manifestations. Heat stroke can be further subdivided into "exertional heat stroke" occurring in generally healthy individuals undergoing strenuous physical activity in warm conditions and "non-exertional heat stroke" often seen in elderly and/or debilitated patients with impaired thermal regulations due to illness or medications (see Etiology).

SYNONYMS

Heat illness
Hyperthermia

ICD-10CM CODES

T67.5 Heat exhaustion, unspecified
T67.0 Heatstroke and sunstroke
T67.1 Heat syncope
T67.2 Heat cramp
T67.3 Heat exhaustion, anhydrotic
T67.6 Heat fatigue, transient

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Incidence of heat stroke is approximately 20 cases/100,000 population.
PREDOMINANT AGE: Heat exhaustion and stroke occur more frequently in elderly patients, especially those taking diuretics or medications that impair heat dissipation (e.g., phenothiazines, anticholinergics, antihistamines, beta-blockers). Table 1 describes factors predisposing to serious heat illness.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Heat exhaustion:

- Generalized malaise, weakness, headache, muscle and abdominal cramps, nausea, vomiting, hypotension, tachycardia.
- Rectal temperature is usually normal.
- Sweating is usually present.

Heat stroke:

- Neurologic manifestations (seizures, tremor, hemiplegia, coma, psychosis, other bizarre behavior)
- Evidence of dehydration (poor skin turgor, sunken eyeballs)
- Tachycardia, hyperventilation
- Skin is hot, red, and flushed
- Sweating is often (not always) absent, particularly in elderly patients
- Classic heat stroke generally develops slowly over days and occurs predominantly in older persons and in those with chronic illness. Exertional heat stroke is more common in young, healthy persons, has a more rapid onset, and is associated with higher core temperatures. Table 2 compares classic and exertional heat stroke. Box 1 summarizes organ dysfunction seen in patients with heat stroke

ETIOLOGY

- Exogenous heat gain (increased ambient temperature)
- Increased heat production (exercise, infection, hyperthyroidism, drugs)
- Impaired heat dissipation (high humidity, heavy clothing, neonatal or elderly patients, drugs [phenothiazines, anticholinergics, antihistamines, butyrophenones, amphetamines, cocaine, alcohol, β-blockers])

TABLE 1 Factors Predisposing to Serious Heat Illness

Individual Factors

Lack of acclimatization
Low physical fitness
Excessive body weight
Dehydration
Advanced age
Young age

Health Conditions

Inflammation and fever
Viral infection
Cardiovascular disease
Diabetes mellitus
Gastroenteritis
Rash, sunburn, and previous burns to large areas of skin
Seizures
Thyroid storm
Neuroleptic malignant syndrome
Malignant hyperthermia
Sickle cell trait
Cystic fibrosis
Spinal cord injury

Drugs

Anticholinergic properties (atropine)
Antiepileptic (topiramate)
Antihistamines
Glutethimide (Doriden)
Phenothiazines
Tricyclic antidepressants
Amphetamines, cocaine, "ecstasy"
Ergogenic stimulants (e.g., ephedrine, ephedra)
Lithium
Diuretics
β-Blockers
Ethanol

Environmental Factors

High temperature
High humidity
Little air motion
Lack of shade
Heat wave
Physical exercise
Heavy clothing
Air pollution (nitrogen dioxide)

From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

- Diuretics, laxatives
- Fig. E1 describes an algorithm of the pathophysiology of heat stroke

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infections (meningitis, encephalitis, sepsis)
- Head trauma
- Epilepsy
- Thyroid storm
- Acute cocaine intoxication
- Malignant hyperthermia
- Heat exhaustion can be differentiated from heat stroke by the following:
  1. Essentially intact mental function and lack of significant fever in heat exhaustion
  2. Mild or absent increases in creatine phosphokinase (CPK), aspartate aminotransferase (AST), lactate dehydrogenase (LDH), and alanine aminotransferase (ALT) in heat exhaustion

WORKUP

- Heat stroke: Comprehensive history, physical examination, and laboratory evaluation.
- Heat exhaustion: In most cases, laboratory tests are not necessary for diagnosis.

LABORATORY TESTS

Laboratory abnormalities may include the following:

- Elevated blood urea nitrogen (BUN), creatinine, hematocrit
- Hyponatremia or hypernatremia, hyperkalemia or hypokalemia
- Elevated LDH, AST, ALT, CPK, bilirubin
- Lactic acidosis, respiratory alkalosis (from hyperventilation)
- Myoglobinuria, hypofibrinogenemia, fibrinolysis, hypocalcemia

TREATMENT

- Treatment of heat exhaustion consists primarily of placing the patient in a cool, shaded area and providing rapid hydration and salt replacement.
  1. Fluid intake should be at least 2 L q4h in patients without history of CHF.
  2. Salt replacement can be accomplished by using one-quarter teaspoon of salt or two 10-grain salt tablets dissolved in 1 L of water.
  3. If IV fluid replacement is necessary, young athletes can be given normal saline IV (3 to 4 L over 6 to 8 hr); in elderly patients, consider using D5½NS IV with the rate titrated to cardiovascular status.
- Patients with heat stroke should undergo rapid cooling.
  1. Remove the patient's clothes and place the patient in a cool and well-ventilated room.
  2. If patient is unconscious, position on his or her side and clear the airway. Protect airway and augment oxygenation (e.g., nasal O_2 at 4 L/min to keep oxygen saturation >90%).

TABLE 2 Comparison of Classic and Exertional Heat Stroke

Patient Characteristics	Classic	Exertional
Age	Young children or elderly	15-55 yr
Health	Chronic illness	Usually healthy
Fever	Unusual	Common
Prevailing weather	Frequent in heat waves	Variable
Activity	Sedentary	Strenuous exercise
Drug use	Diuretics, antidepressants, anticholinergics, phenothiazines	Ergogenic stimulants or cocaine
Sweating	Often absent	Common
Acid-base disturbances	Respiratory alkalosis	Lactic acidosis
Acute renal failure	Uncommon	Common (≈15%)
Rhabdomyolysis	Uncommon	Common (≈25%)
CK	Mildly elevated	Markedly elevated (500-1000 U/L)
ALT, AST	Mildly elevated	Markedly elevated
Hyperkalemia	Uncommon	Common
Hypocalcemia	Uncommon	Common
DIC	Mild	Marked
Hypoglycemia	Uncommon	Common

ALT, Alanine aminotransferase; *AST,* aspartate aminotransferase; *CK,* creatine kinase; *DIC,* disseminated intravascular coagulation.

BOX 1 Organ Dysfunction Seen in Patients with Heat Stroke

Encephalopathy
Rhabdomyolysis
Acute renal failure
Acute respiratory distress syndrome
Myocardial injury
Hepatocellular injury
Intestinal ischemia and infarction
Pancreatic injury
Hemorrhagic complication (e.g., disseminated intravascular coagulation)

From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

3. Monitor body temperature every 5 min. Measurement of the patient's core temperature with a rectal probe is recommended. The goal is to reduce the body temperature to 39° C (102.2° F) in 30 to 60 min. Advantages, disadvantages, and efficacy of various cooling methods are described in Table E3.
4. Spray the patient with a cool mist and use fans to enhance airflow over the body (rapid evaporation method).
5. Immersion of the patient in ice water, stomach lavage with iced saline solution, intravenous administration of cooled fluids, and inhalation of cold air are advisable only when the means for rapid evaporation are not available. Immersion in tepid water (15° C, 59° F) is preferred over ice water immersion to minimize risk of shivering.
6. Use of ice packs on axillae, neck, and groin is controversial because they increase peripheral vasoconstriction and may induce shivering.
7. Antipyretics are ineffective because the hypothalamic set point during heat stroke is normal despite the increased body temperature.
8. Intubate a comatose patient, insert a Foley catheter, and start nasal O_2. Continuous ECG monitoring is recommended.
9. Insert at least two large-bore IV lines and begin IV hydration with normal saline (NS) or Ringer lactate.
10. Draw initial laboratory studies: Electrolytes, complete blood count, blood urea nitrogen, creatinine, AST, ALT, CPK, LDH, glucose, PT (INR), PTT, platelet count, Ca^{2+}, lactic acid, and arterial blood gases.
11. Treat complications as follows:
    a. Hypotension: Vigorous hydration with normal saline or Ringer lactate
    b. Convulsions: Diazepam 5 to 10 mg IV (slowly)
    c. Shivering: Chlorpromazine 10 to 50 mg IV
    d. Acidosis: Use bicarbonate judiciously (only in severe acidosis)

- Observe for evidence of rhabdomyolysis and hepatic, renal, or cardiac failure and treat accordingly.

DISPOSITION

Most patients recover completely within 48 hr. Central nervous system injury is permanent in 20% of cases. Mortality rate can exceed 30% in patients with prolonged and severe hyperthermia. Delayed access to cooling is the leading cause of morbidity and mortality in persons with heat stroke.

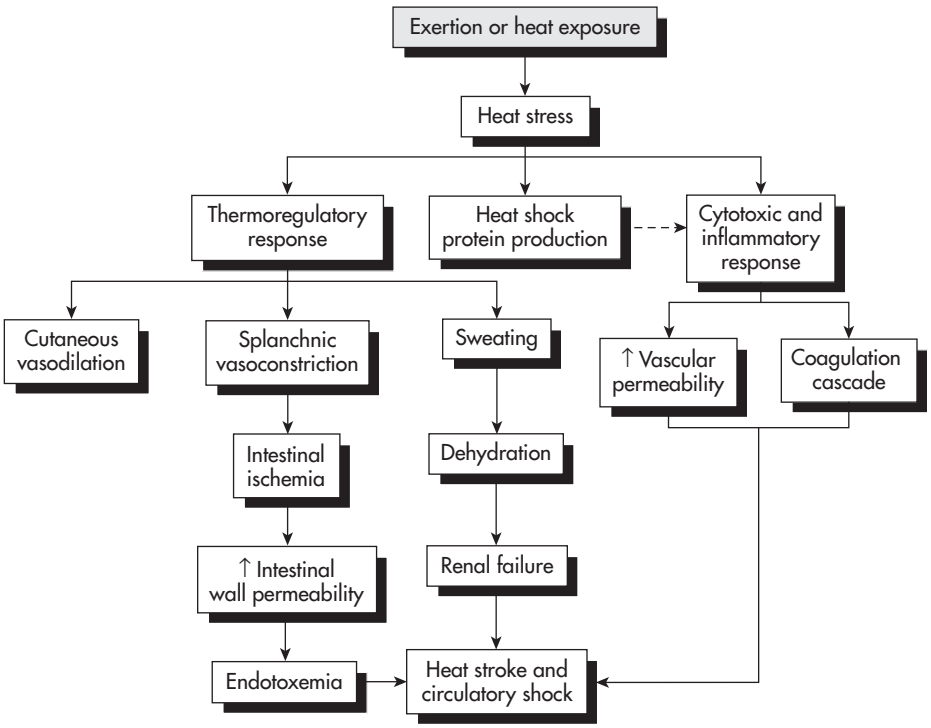

FIG. E1 Algorithm of the pathophysiology of heat stroke. (From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.)

TABLE E3 Advantages, Disadvantages, and Efficacy of Various Cooling Methods

Cooling Method	Advantages	Disadvantages	Effectiveness
Antipyretics		Can worsen liver or renal injury	Not effective (the temperature set-point is not elevated in hyperthermia) Not effective in controlling pathologic inflammation
Evaporative cooling	Noninvasive, easy to monitor, readily available	Labor-intensive—requires constant moistening of skin	Comparison studies show the cooling rate on average to be slower than immersion Published rate range: 0.05-0.31° C/min (32.09-32.56° F/min)
Immersion	Noninvasive, rapid	Cumbersome, poorly tolerated, safety questionable if comorbid conditions present, monitoring difficult, shivering and vasoconstriction	Comparison studies show the cooling rate on average to be faster than evaporation Published rate range: 0.04-0.35° C/min (32.07-32.63° F/min)
Immersion of the hands and forearms	Noninvasive, easy to perform in the field	Shivering and vasoconstriction	Slower cooling but appropriate for mildly ill patients, such as those with heat exhaustion
Ice packing	Noninvasive, readily available	Shivering and vasoconstriction, poorly tolerated	Less effective than immersion or evaporation Some authorities recommend using both evaporation and ice
Cold gastric or peritoneal lavage	Very rapid	Invasive, cumbersome (cold sterile saline needed for peritoneal lavage)	In canine studies, questionably faster than evaporation or immersion
Dantrolene	In theory, decreases heat production by inhibiting muscle contraction		No clear efficacy; it may be more effective for exertional than for classic heat stroke
Benzodiazepines	Treatment of shivering to decrease heat production and heat-induced seizures	Sedation	Whether treatment increases cooling is unknown but may make cooling treatments tolerable Also effective for heat-related seizures

From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

BASIC INFORMATION

DEFINITION

Abnormal uterine bleeding (AUB) is a broad term for variations in normal menses. Normal duration of menstrual flow is 5 days; normal menstrual cycle is 21 to 35 days. Heavy menstrual bleeding, or menorrhagia, is a large volume of menstrual blood loss (i.e., >80 ml per cycle). Bleeding may also be prolonged, intermenstrual, frequent, and irregular. This language replaces prior terms such as *metrorrhagia, polymenorrhea,* or *oligomenorrhea.*

PALM-COEIN classification of abnormal uterine bleeding was adopted in 2011 to standardize terminology and reflect etiology: Polyp, adenomyosis, leiomyoma, malignancy and hyperplasia, coagulopathy, ovulatory dysfunction, endometrial, iatrogenic, and not yet classified. AUB-P would refer to abnormal uterine bleeding due to polyps.

SYNONYMS

Menometrorrhagia
Dysfunctional uterine bleeding
Irregular menstrual cycle

ICD-10CM CODES

N92.0	Excessive and frequent menstruation with regular cycle
N92.1	Excessive and frequent menstruation with irregular cycle
N92.2	Excessive menstruation at puberty
N92.4	Excessive bleeding in the premenopausal period
N92.6	Irregular menstruation, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 10% to 15% of reproductive-aged women; 30% of outpatient office visits; 70% of all gynecologic consults
PEAK INCIDENCE: Reproductive-aged women, ages 13 to 50
PREVALENCE: 9% to 14% of all women
PREDOMINANT SEX AND AGE: Female; peak in adolescence and perimenopausal periods
GENETICS: Hereditary coagulopathy (most commonly von Willebrand disease, platelet dysfunction disorders) in 20% of women with heavy menstrual bleeding
RISK FACTORS: Genetic predisposition, anticoagulation treatment, obesity, endocrinopathies, autoimmune disease, liver disease, renal disease

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History: Age, age at menarche or menopause, menstrual bleeding patterns, severity of bleeding, pain, underlying medical conditions, surgical history, medications, family history, hirsutism, acne, symptoms of thyroid dysfunction or other endocrinopathy
  1. If heavy bleeding since menarche, screen for signs and symptoms of hemostatic disorder, including postpartum hemorrhage, surgery-related bleeding, bleeding from dental work, easy bruising, epistaxis, and frequent gum bleeding
- Physical exam: Weight, hirsutism, acne, thyroid nodules, signs of insulin resistance (acanthosis nigricans), signs of bleeding disorder (petechiae, ecchymoses, pallor, swollen joints), pelvic examination including external, speculum, and bimanual exam of uterus

ETIOLOGY

- Pregnancy/miscarriage
- Endometrial polyps
- Adenomyosis
- Uterine leiomyoma
- Endometrial hyperplasia or carcinoma
- Coagulopathy, inherited or acquired
- Ovulatory dysfunction, most likely PCOS
- Endometrial
- Arteriovenous malformation
- Infection
- Iatrogenic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Pregnancy, sexually transmitted infection, polycystic ovary syndrome (PCOS), thyroid dysfunction, anovulation due to immature hypothalamic-pituitary-ovarian axis or perimenopausal transition, uterine pathology including endometrial hyperplasia or carcinoma, leiomyoma, adenomyosis, or endometrial polyp, coagulopathy, iatrogenic due to medications including oral contraceptives or anticoagulants (warfarin), nonuterine bleeding (urinary, gastrointestinal, vaginal, or cervical source)

WORKUP

- History
- Physical exam
- Laboratory, pathology, and imaging studies to determine etiology

LABORATORY TESTS

- Pregnancy test
- Complete blood count (CBC)
- Thyroid-stimulating hormone (TSH)
- *Chlamydia trachomatis* testing if high risk
- Pap smear if indicated
- Targeted screening for bleeding disorders
- Endometrial sampling by endometrial biopsy or hysteroscopic sampling for women >45 yr or <45 yr with history of unopposed estrogen (PCOS, obesity), failed medical management, or persistent abnormal bleeding
- Iron studies if anemia is suspected

IMAGING STUDIES

- Pelvic ultrasound, transabdominal and transvaginal
- Sonohysterography or hysteroscopy if ultrasound is not adequate or further evaluation of the cavity is required
- MRI if needed for surgical planning or further evaluation of structural abnormality

TREATMENT

SURGICAL MANAGEMENT

- Dilation and curettage
- Hysteroscopic resection of uterine pathology including endometrial polyps and submucosal leiomyoma
- Myomectomy
- Endometrial ablation
- Uterine artery embolization
- Hysterectomy

ACUTE GENERAL Rx

Acute severe bleeding may be managed medically with oral progestins, combined oral contraceptive pills, IV estrogen, tranexamic acid, and/or blood transfusion as indicated. Surgical management includes dilation and curettage, uterine artery embolization, or hysterectomy.

CHRONIC Rx

- Combined hormonal contraceptives (pill, transdermal patch, vaginal ring) in a cyclic or continuous regimen
- Progesterone intrauterine device
- Oral or injected progesterone
- Gonadotropin-releasing hormone analog
- Nonsteroidal antiinflammatory drugs
- Tranexamic acid, aminocaproic acid
- Danazol (significant side-effect profile requires justification for use; this is rare)
- Selective progesterone receptor modulators (investigational for bleeding related to leiomyomas)
- Surgery for anatomic causes, including polypectomy or myomectomy
- Uterine artery embolization for leiomyomatous uterus
- Endometrial ablation or hysterectomy if completed childbearing
- Replacement of or treatment for any abnormal bleeding factors (i.e., DDAVP)

REFERRAL

- If unresponsive to initial hormonal management, referral to gynecologist is warranted.
- If concern for a structural etiology or malignancy, referral to a gynecologist for surgical management is indicated.
- If endometrial sampling reveals endometrial hyperplasia or malignancy, referral to a gynecologist or gynecologic oncologist is indicated. Resampling is necessary with progestin therapy for hyperplasia. If endometrial hyperplasia associated with complex glands or atypia, consultation with gynecologic oncologist is warranted due to high degree of progression to malignancy.

BASIC INFORMATION

DEFINITION

Infection of the human gastric mucosa with the organism *Helicobacter pylori,* a spiral-shaped gram-negative organism with unique features that allow it to survive in the hostile gastric environment.

SYNONYM

Previously known as *Campylobacter pylori*

ICD-10CM CODE

B96.81 *Helicobacter pylori* [*H. pylori*] as the cause of diseases classified elsewhere

EPIDEMIOLOGY & DEMOGRAPHICS

H. pylori is the most common chronic bacterial infection in human beings, probably affecting 50% of the Earth's population in all age groups as well as 30% to 40% of the U.S. population. In developing nations, infection is acquired at an earlier age and occurs more frequently.

CLINICAL PRESENTATION

- *H. pylori* causes histologic gastritis in all affected individuals. The majority of cases are asymptomatic and unlikely to proceed to serious consequences.
- *H. pylori* is a causative agent in peptic ulcer disease (PUD), gastric adenocarcinoma, and gastric mucosa-associated lymphoid tissue lymphoma, as well as a risk factor for iron-deficiency anemia and likely chronic idiopathic thrombocytopenic purpura. It may present with the signs and symptoms of these disorders, including abdominal pain, bloating, anorexia, and early satiety. Fig. 1 describes association of *H. pylori* infection and disease states.
- "Alarm symptoms" that should prompt more immediate and aggressive workup include weight loss, dysphagia, protracted nausea or vomiting, anemia, melena, and palpable abdominal mass, particularly in older individuals.

ETIOLOGY

- Route of acquisition is unknown but is presumed to be person to person by fecal-oral or possibly oral-oral transmission.
- The majority of cases are acquired in childhood. Socioeconomic status and living conditions in childhood affect risk of acquisition of infection. These factors include housing density, number of siblings, overcrowding, sharing a bed, and lack of running water.
- Iatrogenic transmission has been documented.
- *H. pylori* does not invade gastroduodenal tissue, but disrupts the mucous layer, causing the underlying mucosa to be more vulnerable to acid peptic damage.
- It is unclear what differentiates the subset of patients with *H. pylori* who go on to develop ulcers or cancer.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection with *H. pylori* should be considered in the face of PUD, gastric cancer, gastritis, and gastric mucosa-associated lymphoid tissue (MALT) lymphoma.
- *H. pylori* should be considered in the differential diagnosis of upper gastrointestinal (GI) tract disease, along with nonulcer dyspepsia, reflux esophagitis, biliary tract disease, gastroparesis, pancreatitis, ischemic bowel, and unexplained iron deficiency anemia.

WORKUP

- Workup is indicated in patients with active PUD, a past history of documented peptic ulcer, or gastric MALT lymphoma, as well as those with immune thrombocytopenic purpura (ITP), and otherwise unexplained iron deficiency. The role of routine screening in high-risk populations is not clear. However, numerous studies suggest that *H. pylori* eradication is protective against progression of premalignant gastric lesions. Consider testing those starting long-term NSAID, low-dose aspirin, or proton pump inhibitor (PPI) therapy. Routine identification and treatment of *H. pylori* in cases of nonulcer dyspepsia, gastroesophageal reflux disease (GERD), and in asymptomatic individuals in populations at high risk for gastric cancer is considered controversial. There is insufficient evidence to advocate screening in asymptomatic first-degree relatives of gastric cancer patients. A test-and-treat strategy may be used in patients younger than 55 with uncomplicated dyspepsia who have no alarm symptoms.
- Results of testing must be interpreted in relation to the individual patient's likelihood of *H. pylori* infection based on demographic risk factors. In the U.S. population, increased probability of infection exists in African Americans, Hispanics/Latinos, immigrants from developing nations, patients with poor socioeconomic status, Native Americans from Alaska, and persons >50 yr.
- Routine screening for *H. pylori* is not indicated in asymptomatic patients who are at low risk of infection.
- Infected patients with functional dyspepsia often benefit from treatment and should be evaluated for *H. pylori.*

LABORATORY TESTS

- Testing may be invasive or noninvasive depending on the need for endoscopy for other indications. There is no indication for endoscopy solely to diagnose *H. pylori.*
- Tests for *H. pylori* are differentiated as active or passive. Active tests provide direct evidence that *H. pylori* infection is currently present and include urea breath testing and stool antigen testing. Passive testing, which includes all serologic testing for *H. pylori,* detects the presence of antibodies to the organism. It is limited by its inability to distinguish between active current infection and prior infection that has resolved.
- Tests that use urease as a marker (urea breath and stool antigen tests and biopsy for urease activity) may result in false-negative results in patients taking antibiotics, bismuth, or antisecretory therapy, as well as those with active ulcer bleeding. Patients should be off antibiotics for 4 wk and off protein pump inhibitors for 2 wk before urea breath or stool antigen testing.

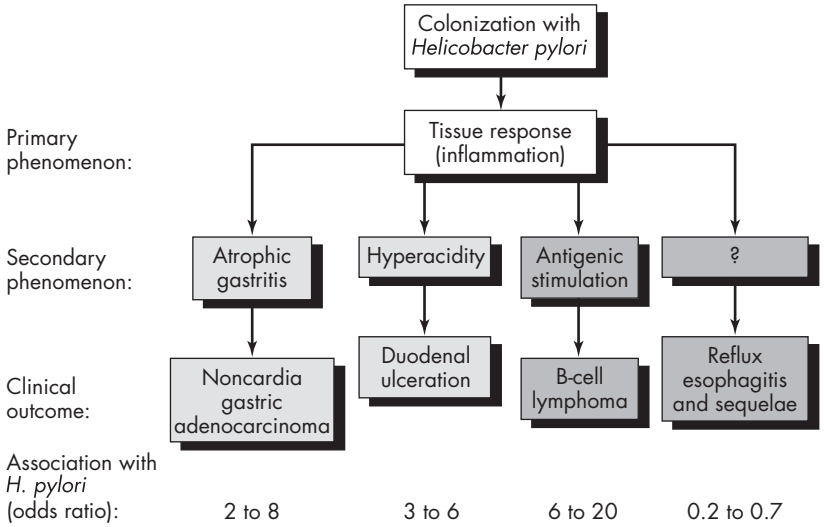

FIG. 1 Association of *Helicobacter pylori* colonization and disease states. After *H. pylori* acquisition, virtually all persons develop persistent colonization that lasts for life. Colonization induces tissue responses termed *chronic gastritis.* This process affects gastric physiology, including glandular structure, acid secretion, and antigen processing, which in turn affect disease risk. Colonization with *H. pylori* increases the risk for certain diseases (duodenal ulcer, gastric ulcer, noncardiac gastric adenocarcinoma, and B-cell lymphomas) but appears to decrease the risk for gastroesophageal reflux disease and its complications, including Barrett esophagus, and adenocarcinoma of the esophagus or gastric cardia. (From Mandell GL et al: *Principles and practice of infectious diseases,* ed 7, Philadelphia, 2010, Churchill Livingstone.)

- When diagnostic endoscopy is indicated (for suspicion or follow-up of PUD or gastric MALT), antral biopsy should be tested for urease activity. If urease testing is likely to show a false-negative result because of recent proton pump inhibitor (PPI), bismuth, or antibiotic use or active ulcer bleeding, the sample should undergo histologic examination.
- In cases in which biopsy is not indicated, urea breath testing or stool antigen testing is indicated to evaluate for active infection. Urea breath testing is slightly more expensive than stool antigen testing, but both costs are in the modest range. Choice can be made based on patient preference and availability. The sensitivities and specificities of these two tests are similar (>90%), but sensitivity may be reduced in the face of active upper GI bleed or recent PPI use.
- Serologic testing should be avoided, although it may be useful in low-risk patients in areas with low prevalence to confirm lack of infection. In this situation, positive results should be confirmed with an active testing method.

Rx TREATMENT

ACUTE GENERAL Rx

- Test only patients whom you intend to treat if positive (see "Workup"). At this time, the value of eradicating *H. pylori* infection has been clearly demonstrated in patients with PUD or gastric MALT lymphoma.
- The optimal antibiotic regimen remains undefined. In addition to efficacy, side effects, cost, and ease of administration must be considered.
- Due to increasing resistance to clarithromycin, decisions regarding appropriate regimens should take into account local rates of clarithromycin resistance, as well as any prior macrolide exposure for the patient. Clarithromycin resistance can be assumed to be >15% in the U.S., unless local resistance information is available.
- The following regimens may be considered for first-line therapy:
  1. Quadruple therapy: PPI (esomeprazole 20 mg, lansoprazole 30 mg, pantoprazole 40 mg, omeprazole 40 mg, or rabeprazole 20 mg, all given bid), with twice-daily clarithromycin (500 mg) amoxicillin (1 g bid), and metronidazole 500 mg bid for 10 to 14 days.
  2. Bismuth quadruple therapy: PPI twice daily (see earlier) combined with bismuth subsalicylate (Pepto-Bismol and others) 262 or 525 mg four times daily, as well as tetracycline (500 mg qid) and metronidazole (250 mg qid or 500 mg tid-qid) for 10 to 14 days. This is now recommended as first-line therapy in areas of high clarithromycin resistance and in patients with penicillin allergy.
- Current guidelines recommend extended treatment of 10 to 14 days. Use of combination capsules may improve compliance but is likely to be more expensive.
- Recent guidelines suggest multiple other regimens that can be considered based on local resistance patterns and patient's allergy profile.
- Prior exposure to a macrolide or metronidazole, for any reason, is associated with increased resistance. A preferable regimen would include medications to which the patient has not been previously exposed.
- Diarrhea and abdominal cramping are commonly observed with many of the regimens. (Probiotics may diminish this effect.) Other side effects may include a metallic taste with metronidazole or clarithromycin, neuropathy, seizures, and disulfiram-like reaction with metronidazole, diarrhea with amoxicillin, photosensitivity with tetracycline, and *Clostridium difficile* infection with any antibiotic exposure. Bismuth may cause black stool and constipation. Tetracycline is contraindicated in pregnant patients.
- 20% of patients may not respond to initial therapy. It is important to reinforce compliance. Second-line therapy should avoid antibiotics used in initial treatment and should include either bismuth-containing quadruple therapy or levofloxacin-containing triple therapy (regardless of local clarithromycin resistance patterns). When possible, management of those who do not respond to two courses of therapy should be guided by antimicrobial sensitivity testing (endoscopy with biopsy for cultures and sensitivity).

CHRONIC Rx

- It is essential to document clearance of infection after the completion of treatment. Repeat testing is generally performed 1 mo after completion of antibiotics and at least 2 wk after cessation of PPI therapy.
- Active tests such as urea breath test and stool antigen testing should be used. They are equally accurate in confirming eradication, and either may be used depending on availability and patient preference.
- Serology does not reliably revert to undetectable levels after treatment and should not be used to determine eradication.

DISPOSITION

Consider further evaluation in patients with recurrent symptoms after appropriate treatment.

REFERRAL

- Patients with gastric MALT lymphoma should be followed by a gastroenterologist and oncologist with expertise in the care of lymphoid neoplasms.
- Patients with dyspepsia who have tested positive for *H. pylori* and failed two courses of treatment should be referred for endoscopy and biopsy for culture and sensitivity.

PEARLS & CONSIDERATIONS

- It remains unclear whether *H. pylori* eradication reduces the risk of progression to gastric cancer.
- Outcomes in PUD and gastric MALT lymphoma are improved with treatment of associated *H. pylori* infection.
- Tests that provide direct evidence of active *H. pylori* infection (urea breath and stool antigen testing) are preferred. These may result in false-negative results in patients taking antibiotics, bismuth, or antisecretory agents, which should be stopped at an appropriate time interval before testing.
- Serologic testing does not differentiate active from prior infection. If performed, positive results should be confirmed with active testing.
- Be aware of high-risk populations in low-prevalence settings, including immigrants from Mexico, South America, Southeast Asia, and Eastern Europe.

BASIC INFORMATION

DEFINITION

The HELLP syndrome is a serious variant of preeclampsia. HELLP is an acronym for ***h***emolysis, ***e***levated ***l***iver enzymes, and ***l***ow ***p***latelet count. It is the most frequently encountered microangiopathy of pregnancy. Two classification systems exist (Mississippi Classification and Tennessee Classification); degree of maternal thrombocytopenia is a primary indicator of disease severity:

	Tennessee	Mississippi
Class 1:	Platelets <100,000/mm^3 AST or ALT >70 IU/L	Platelets <50,000/mm^3 AST or ALT >70 IU/L
Class 2:		Platelets >50,000/mm^3 to <100,000/mm^3 AST or ALT >70 IU/L
Class 3:		Platelets >100,000/mm^3 to <150,000/mm^3 AST or ALT ≥70 IU/L

ALT, Alanine aminotransferase; *AST,* aspartate aminotransferase. All criteria require LDH ≥600 IU/L.

SYNONYMS

HELLP
Hemolysis
Elevated liver enzymes
Low platelet syndrome

ICD-10CM CODES

O14.2	HELLP syndrome
O26.892	Other specified pregnancy related conditions, second trimester
O26.893	Other specified pregnancy related conditions, third trimester
O26.899	Other specified pregnancy related conditions, unspecified trimester
O26.90	Pregnancy related conditions, unspecified, unspecified trimester
O26.91	Pregnancy related conditions, unspecified, first trimester
O26.92	Pregnancy related conditions, unspecified, second trimester
O26.93	Pregnancy related conditions, unspecified, third trimester

EPIDEMIOLOGY & DEMOGRAPHICS

- HELLP is a rare complication occurring in <1% of total pregnancies.
- Among women with severe preeclampsia, 6% will manifest with one abnormality suggestive of HELLP syndrome, 12% will develop two abnormalities, and approximately 10% will develop all three.
- The HELLP syndrome, like preeclampsia, is rare before 20 wk of gestation and the majority of cases occur during the third trimester.
- One third of all cases occur postpartum; of these, only 80% are typically diagnosed with preeclampsia before delivery.
- Younger age, headache, bilirubin >2.0, LDH >1290, and platelets <50k are predictive of worse maternal outcomes.

RISK FACTORS: Women >35 yr, white, multiparity, heritable genetics
RECURRENCE RATE: 3% to 25%

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Definitive laboratory criteria remain to be validated prospectively.
- Most commonly used criteria include hemolysis defined by the presence of an abnormal peripheral smear with schistocytes, lactate dehydrogenase (LDH) >600 U/L, and total bilirubin >1.2 mg/dl; elevated liver enzymes (serum aspartate aminotransferase (AST) >70 U/L); low platelet count as less than 100,000/ml.
- Although many women with HELLP syndrome are asymptomatic, 80% report right upper quadrant pain, and 50% to 60% present with excessive weight gain and worsening edema.

ETIOLOGY

As with other microangiopathies, endothelial dysfunction, with resultant activation of the intravascular coagulation cascade, has been proposed as the central pathogenesis of HELLP syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute fatty liver of pregnancy
- Thrombotic thrombocytopenic purpura/hemolytic-uremic syndrome
- Appendicitis
- Gallbladder disease
- Peptic ulcer disease
- Enteritis
- Hepatitis
- Pyelonephritis
- Systemic lupus erythematosus
- Box E1 summarizes medical and surgical disorders often confused with HELLP syndrome

WORKUP

Because HELLP syndrome is a disease entity based on laboratory values, initial assessment is detailed below.

LABORATORY TESTS

- Initial assessment of suspected HELLP syndrome should include a complete blood count to evaluate platelets, urinalysis, serum creatinine, LDH, uric acid, indirect and total bilirubin levels, and AST/alanine aminotransferase (ALT).
- Tests of prothrombin time, partial thromboplastin time, fibrinogen, and fibrin split products are reserved for women with a platelet count well below 100,000/mm^3.

IMAGING STUDIES

Imaging should be considered in the setting of severe abdominal pain and transaminitis to evaluate for hepatic hematoma and rupture.

TREATMENT

Treatment depends on gestational age of the fetus, severity of condition, and maternal status. Stabilization of the mother is the first priority. Fig. E1 describes an algorithm for the management of HELLP syndrome.

ACUTE GENERAL Rx

- Assess gestational age thoroughly. Fetal status should be monitored with nonstress tests, contraction stress tests, and/or biophysical profile.
- Maternal status should be evaluated by history, physical examination, and laboratory testing.
- Magnesium sulfate is administered for seizure prophylaxis regardless of blood pressure.
- Blood pressure control is achieved with agents such as hydralazine or labetalol.
- Indwelling Foley catheter to monitor maternal volume status and urine output.
- Eculizumab has also been proposed as a possible therapy in case reports.

CHRONIC Rx

- In pregnancies of 34 wk or with class 1 HELLP syndrome, delivery, either vaginal or abdominal, within 48 hr is the goal.
- In the preterm fetus, corticosteroid therapy to enhance fetal lung maturation is indicated.
- Some reports have shown temporary amelioration of HELLP severity with the administration of high-dose steroids measured by increased urine output, improvement in platelet count, and liver function test. A 2015 meta-analysis of multiple studies

BOX E1 Medical and Surgical Disorders Often Confused with HELLP Syndrome

- Acute fatty liver of pregnancy
- Appendicitis
- Gallbladder disease
- Glomerulonephritis
- Hemolytic uremic syndrome
- Hepatic encephalopathy
- Hyperemesis gravidarum
- Idiopathic thrombocytopenia
- Pyelonephritis
- Systemic lupus erythematosus
- Antiphospholipid antibody syndrome
- Thrombotic thrombocytopenic purpura
- Viral hepatitis
- HELLP (hemolysis, elevated liver enzymes, and low platelets) syndrome

From Gabbe SG: *Obstetrics*, ed 6, Philadelphia, 2012, WB Saunders.

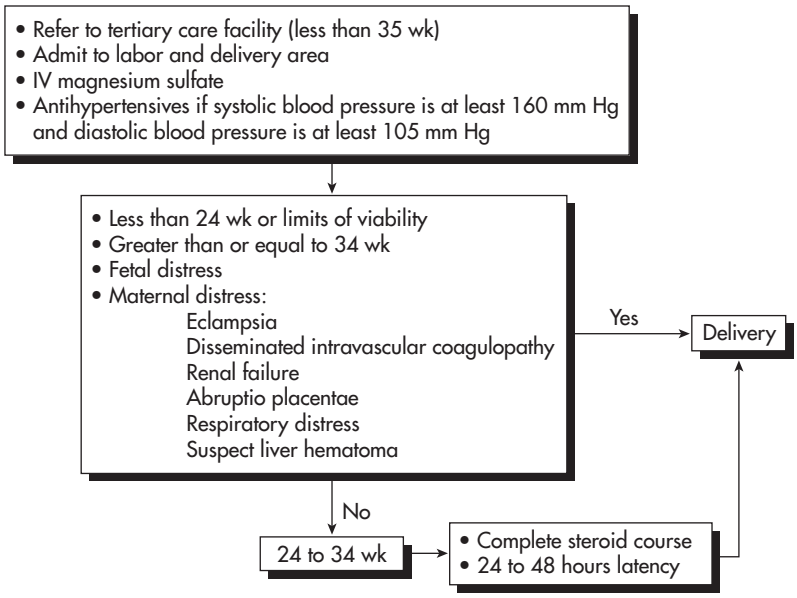

FIG. E1 An algorithm for the management of HELLP syndrome. IV, intravenous. (From Gabbe SG: *Obstetrics*, ed 6, Philadelphia, 2012, WB Saunders.)

suggested improvement in lab parameters and decreased length of ICU stay with steroid administration. However, there was not better maternal mortality and morbidity.
- Judicious use of blood products, especially in those requiring surgery.
- The patient requires intensive observation. Laboratory levels may worsen immediately postpartum but should begin to improve within 48 hr.

DISPOSITION

The natural history of this disorder is a rapidly deteriorating condition requiring close monitoring of maternal and fetal well-being.

REFERRAL

Preterm patients with HELLP syndrome should be stabilized hemodynamically and transferred to a tertiary care center. Term patients can be treated at a local hospital depending on the availability of obstetric, neonatal, and blood banking services.

PEARLS & CONSIDERATIONS

- Not all women with HELLP have hypertension or proteinuria.
- Life-threatening hemorrhage is a rare event in HELLP syndrome. Identifiable risk factors predictive of a major hemorrhage are thrombocytopenia (<100,000/mm^3), AST >70 IU/L, and previous gestations.
- The most effective therapy for HELLP is emergent delivery of the fetus.

Hemochromatosis PTG ALG

BASIC INFORMATION

DEFINITION

Hemochromatosis is an autosomal-recessive disorder that disrupts the body's regulation of iron and is characterized by increased accumulation of iron in various organs (adrenals, liver, pancreas, heart, testes, kidneys, pituitary) and eventual dysfunction of these organs if not treated appropriately.

SYNONYMS

Bronze diabetes
Hereditary hemochromatosis HH

ICD-10CM CODES

E83.110	Hereditary hemochromatosis
E83.111	Hemochromatosis due to repeated red blood cell transfusions
E83.118	Other hemochromatosis
E83.119	Hemochromatosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: In whites, approximately 1 in 385 persons
PREDOMINANT SEX AND AGE: Generally diagnosed in males in their fifth decade. Diagnosis in females is generally not made until 10 to 20 yr after menopause.
GENETICS: Most common genetic disorder in North European ancestry. Homozygosity for the *C282Y* mutation is now found in approximately 5 of every 1000 persons of European descent.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- In earlier stages patients completely asymptomatic and diagnosed due to abnormal laboratory tests
- Hepatic dysfunction leading to hepatomegaly, fibrosis, and eventually cirrhosis
- Noninflammatory arthropathy (Fig. E1)
- Gonadal insufficiency leading to loss of libido and testicular atrophy
- Diabetes mellitus: Risk greater in patients with family history
- Iron-induced cardiac disease resulting in cardiomyopathy, heart failure, and arrhythmias
- Skin pigmentation

ETIOLOGY

- The majority of the patients diagnosed with hemochromatosis have mutation in the *HFE* gene and are either homozygous for the *C282Y* mutation *(C282Y/C282Y)* or compound heterozygote for the *C282Y* mutation and either the mutation *H63D (C282Y/H63D)* or less commonly the *S65C (C282Y/S65C).*
- The remainder of the patients are classified as non–*HFE*-associated hemochromatosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hereditary anemias with defect of erythropoiesis
- Cirrhosis, chronic liver disease, porphyria cutanea tarda
- Repeated blood transfusions
- Table 1 summarizes hereditary causes of iron overload

WORKUP

Medical history, physical examination, and laboratory evaluation should be focused on affected organ systems (see "Physical Findings & Clinical Presentation"). Fig. E2 outlines evaluation for possible hereditary hemochromatosis in an individual with negative family history. Liver biopsy is the gold standard for diagnosis; it reveals iron deposition in hepatocytes, bile ducts, and supporting tissues.

LABORATORY TESTS

- Transferrin saturation is the best screening test. Values >45% are an indication for further testing.
- Elevated serum ferritin is good evidence of iron overload, but other causes like chronic inflammatory conditions, malignancy, and so forth need to be ruled out as ferritin is also an acute phase reactant.
- Genotypical screening for *C282Y* and *H63D* mutation in *HFE* gene should be done in patients with high transferrin saturation, elevated ferritin, or both.
- Liver biopsy (Fig. E3) is the gold standard but is not needed in somebody who has a persistently elevated transferrin saturation, elevated ferritin, or both.
- Hepatic iron index can help differentiate between various causes of iron overload.
- Elevated aspartate aminotransferase, alanine aminotransferase, and alkaline phosphatase are seen.
- Hyperglycemia is found.
- Endocrine abnormalities (decreased testosterone, luteinizing hormone, follicle-stimulating hormone) are noted.
- Table 2 describes laboratory findings in patients with hereditary hemochromatosis.

IMAGING STUDIES

Routine radiologic imaging is not needed. MRI (Fig. E4) may show low signal intensity in the liver and can be used to estimate hepatic iron concentration.

TREATMENT

The goal of therapy is the removal of excess iron and maintaining it at a normal or near-normal level. Phlebotomy is first line treatment. The goal is to reduce serum ferritin to 50 to 100 mg/ml. Box E1 summarizes the treatment of *HFE*-related hereditary hemochromatosis.

NONPHARMACOLOGIC THERAPY

Phlebotomy is the treatment of choice.

ACUTE GENERAL Rx

- The timing and frequency of phlebotomy needs to be individualized for each patient.
- For patients with heavy iron overload, twice-weekly phlebotomies should be started. In most patients, weekly phlebotomy is adequate.
- The effectiveness of treatment is monitored by periodic ferritin measurement. The goal is to bring ferritin level below 50 ng/ml.
- Patients with iron overload due to transfusion-dependent anemias may not tolerate phlebotomy. For these patients, iron chelation may be needed.
- The chelating agent deferoxamine has to be given daily as a 9- to 12-hr IV or SC infusion, and compliance is difficult.
- The oral chelating agent deferasirox (Exjade) is effective, but should not be used in patients with high-risk myelodysplastic syndrome because it can cause renal impairment, hepatic impairment, or gastrointestinal hemorrhage, which can be fatal.

CHRONIC Rx

After the ferritin has been brought to less than 50 ng/ml, phlebotomy is needed on an as-needed basis to keep the ferritin at that level.

DISPOSITION

- Serum ferritin measurement is the most useful prognostic indicator of disease severity.
- Prognosis is good if phlebotomy is started early (before onset of cirrhosis or diabetes mellitus); women can have the full phenotypic expression of the disease, including cirrhosis, and should also be aggressively treated.

REFERRAL

For liver biopsy if diagnosis is uncertain

PEARLS & CONSIDERATIONS

COMMENTS

- Persons who are homozygous for the *HFE* gene mutation *C282Y* comprise 85% to 90% of phenotypically affected individuals. Patients who are heterozygous for both *C282Y* and *H63D* generally do not have clinically evident disease unless coexisting factors (e.g., excessive alcohol intake) are present.
- Patients with hemochromatosis and serum ferritin levels <1000 ng/ml are unlikely to have cirrhosis. Liver biopsy to screen for cirrhosis may be unnecessary in such patients.
- Cirrhotic patients must be periodically monitored (ultrasound or CT scan) because of their increased risk of hepatocellular carcinoma.
- *HFE* gene testing for *C282Y* mutation is a cost-effective method of screening relatives of patients with hereditary hemochromatosis. The American College of Gastroenterology recommends genotyping persons who have abnormal iron screening tests and first-degree relatives of those identified with *C282Y* homozygosity.
- Established cirrhosis, hypogonadism, destructive arthritis, and insulin-dependent diabetes mellitus secondary to hemochromatosis cannot be reversed with repeated phlebotomy, but their progress can be slowed.

TABLE 1 Hereditary Iron Overload Disorders

Disorder	Gene, Chromosome Location	Inheritance	Plasma Transferrin Saturation	Plasma Ferritin	Iron Deposition Sites	Clinical Manifestations
Hereditary hemochromatosis, *HFE*-associated (type 1; OMIM235200)	*HFE,* 6p21	Autosomal recessive	Early increase; >45%	Later increase after third decade of life	Parenchymal iron overload affecting hepatocytes, heart, pancreas, other organs	Liver and heart disease, diabetes, gonadal failure, arthritis, skin pigmentation
Hereditary hemochromatosis, *TFR2*-associated (type 3; OMIM604250)	*TFR2,* 7q22	Autosomal recessive	Early increase; >45%	Later increase after third decade of life	Parenchymal iron overload affecting hepatocytes, heart, pancreas, other organs	Liver and heart disease, diabetes, gonadal failure, arthritis, skin pigmentation
Juvenile hemochromatosis, hemojuvelin-associated (type 2A; OMIM 602390)	*HJV,* 1q21	Autosomal recessive	Early increase; >45%	Increased by second decade of life	Parenchymal iron overload affecting hepatocytes, heart, pancreas, other organs	As for hereditary hemochromatosis, but liver involvement less prominent
Juvenile hemochromatosis, hepcidin-associated (type 2B; OMIM613313)	*HAMP,* 19q13	Autosomal recessive	Early increase; >45%	Increased by second decade of life	Parenchymal iron overload affecting hepatocytes, heart, pancreas, other organs	As for hereditary hemochromatosis, but liver involvement less prominent
Hemochromatosis, *DMT1*-associated (OMIM 206100)	*SCL11A2,* 12q13	Autosomal recessive	Early increase; >45%	Normal to moderately elevated	Hepatic iron overload, predominantly in hepatocytes	Severe microcytic anemia, liver dysfunction
Atransferrinemia (OMIM 209300)	*TF,* 3q22	Autosomal recessive	No plasma transferrin	Increased	Parenchymal iron overload affecting hepatocytes, heart, pancreas; no iron stores in bone marrow or spleen	Transfusion-dependent iron-deficiency anemia, growth retardation, poor survival
Aceruloplasminemia (OMIM 604290)	*CP,* 3q24-q25	Autosomal recessive	Decreased	Increased	Marked iron accumulation in basal ganglia, liver, pancreas	Diabetes, progressive neurologic disease, retinal degeneration
Hemochromatosis, ferroportin-associated, with impaired iron export (type 4A; OMIM606069)	*SLC40A1,* 2q32	Autosomal dominant	Remains normal or low	Early increase	Predominantly macrophage iron deposition	None
Hemochromatosis, ferroportin-associated, with hepcidin resistance (type 4B; OMIM606069)	*SLC40A1,* 2q32	Autosomal dominant	Early increase; >45%	Early increase	Parenchymal iron overload affecting hepatocytes, heart, pancreas, other organs	Similar to *HFE*-associated hemochromatosis

TABLE 2 Laboratory Findings in Patients with Hereditary Hemochromatosis

Measurements	Normal Subjects	Patients with Hereditary Hemochromatosis	
		Asymptomatic	Symptomatic
Blood (Fasting)			
Serum iron level (μg/dl)	60-180	150-280	180-300
Serum transferrin level (mg/dl)	220-410	200-280	200-300
Transferrin saturation (%)	20-45	45-100	80-100
Serum ferritin level (ng/ml)			
Men	20-200	150-1000	500-6000
Women	15-150	120-1000	500-6000
Genetic (*HFE* Mutation Analysis)			
C282Y/C282Y	wt/wt‡	*C282Y/C282Y*	*C282Y/C282Y*
*C282Y/H63D**	wt/wt	*C282Y/H63D*	*C282Y/H63D*
Liver			
Hepatic iron concentration			
μg/g dry weight	300-1500	2000-10,000	8000-30,000
μmol/g dry weight	5-27	36-179	140-550
Hepatic iron index†	<1	1 to >1.9	>1.9
Liver histology			
Perls Prussian blue stain	0, 1+	2+ to 4+	3+, 4+

*Compound heterozygote.
†Calculated by dividing the hepatic iron concentration (in μmol/g dry weight) by the age of the patient (in yr). With the increased use of genetic testing in patients with iron overload, the specificity of the hepatic iron index has diminished.
‡wt/wt: wild type (normal).
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

- In patients who are heterozygous for *C282Y* or *H63D* mutation, clinically meaningful iron overload does not develop.
- Screening for hepatocellular carcinoma is reserved for those with hereditary hemochromatosis and cirrhosis.

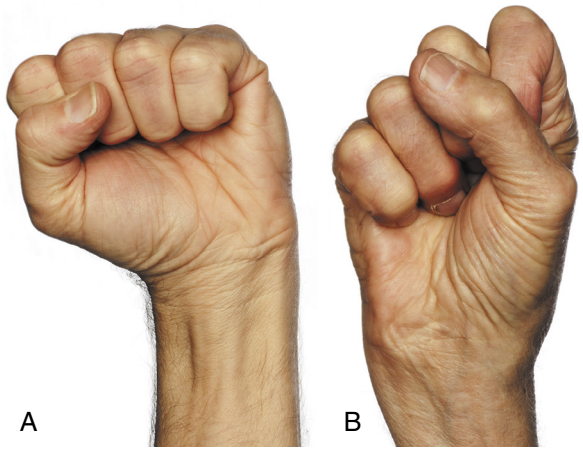

FIG. E1 The iron fist sign in hereditary hemochromatosis (HH) arthropathy. (A) A normal hand. **(B)** Hand in a patient with HH arthropathy. The poor flexion in the index and middle fingers in HH arthropathy is caused by a lack of flexion in the "damaged" metacarpophalangeal 2,3 joints. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

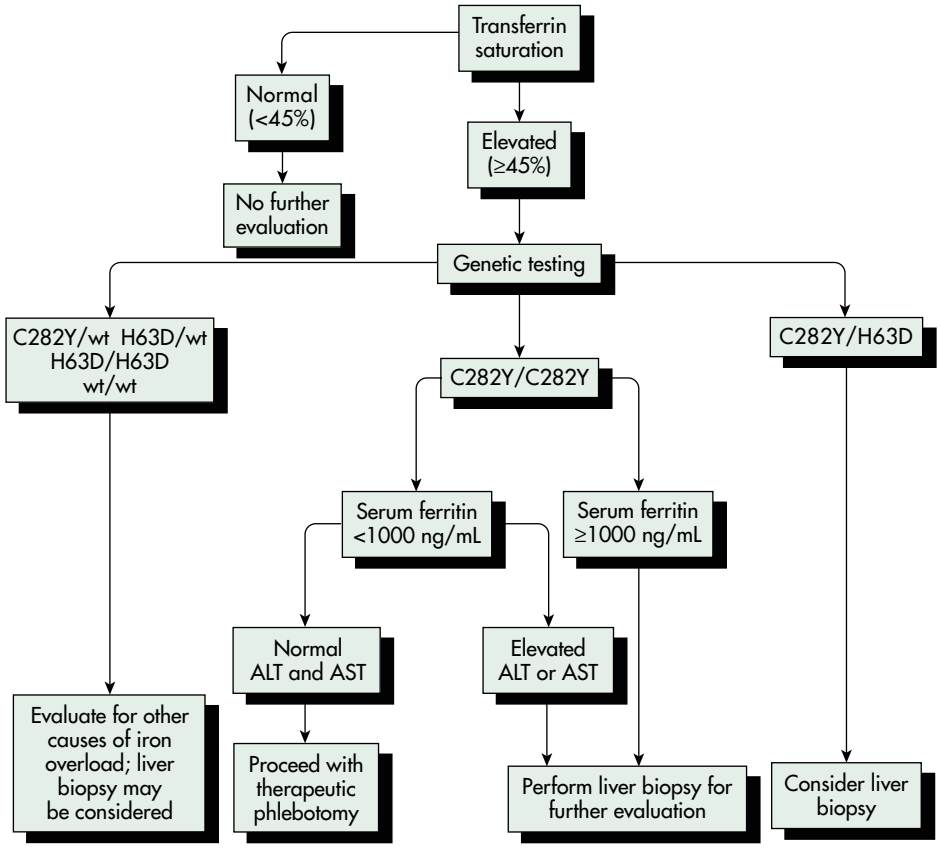

FIG. E2 Algorithm for the evaluation of possible *HFE*-related hereditary hemochromatosis in a person with a negative family history. *ALT,* Alanine aminotransferase; *AST,* aspartate aminotransferase; *wt*, wild-type. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

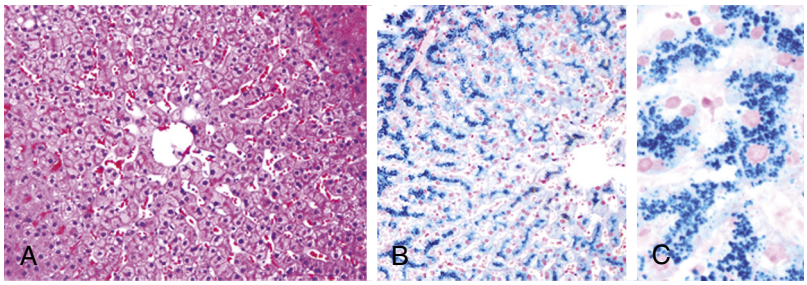

FIG. E3 *HFE* hemochromatosis. Liver biopsy sample from a 46-year-old man with homozygous *HFE* hemochromatosis. Hematoxylin and eosin stain of the liver **(A)** shows intact hepatic architecture. Iron stain **(B, C)** shows marked diffuse iron deposits in the hepatocytes throughout the lobules. A normal liver would show essentially no iron in the hepatocytes. (From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

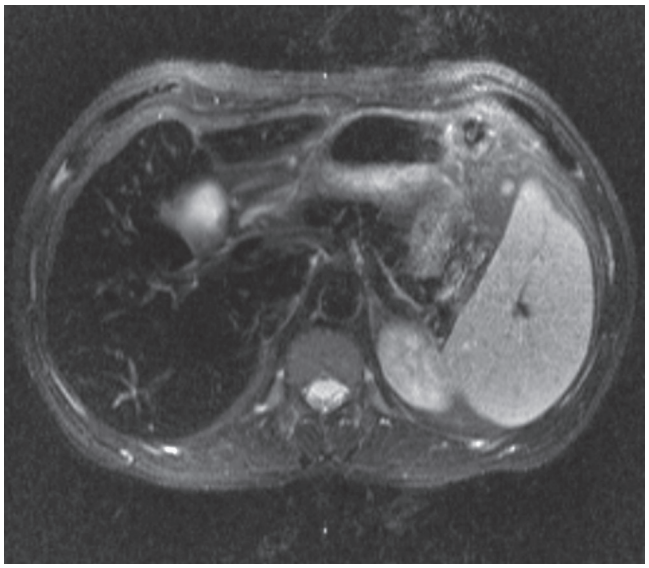

FIG. E4 Magnetic resonance image of a patient with hemochromatosis. This T2-weighted image shows low signal intensity in the liver due to the magnetic susceptibility effects of iron compared with normal signal intensity in the spleen. In secondary iron overload, the spleen would also have low signal intensity due to increased iron deposition in reticuloendothelial cells. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

BOX E1 Treatment of *HFE*-Related Hereditary Hemochromatosis

Perform phlebotomy of 500 ml (1 unit) of whole blood weekly unless the hematocrit value drops below 37%.
Check the transferrin saturation and ferritin levels at 2- to 3-mo intervals to monitor response (optional).
When the iron stores are depleted (ferritin between 50 and 100 ng/ml and transferrin saturation <50%), proceed to maintenance phlebotomy of 1 unit of whole blood every 2-3 mo. Aim to keep the transferrin saturation below 50%; if successful, the ferritin level should remain between 50 and 100 ng/ml.

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

BASIC INFORMATION

DEFINITION

Hemolytic uremic syndrome (HUS) is a life-threatening disorder characterized by microangiopathic hemolytic anemia (MAHA) and severe acute kidney injury. HUS is one of numerous disorders of the broader syndrome known as thrombotic microangiopathy (TMA). HUS, as opposed to some other forms of TMA, is notable for the severity of kidney injury. Although lacking a widely accepted definition, HUS is commonly defined by the presence of acute kidney injury, anemia (hemoglobin < lower limit of normal), hemolysis (lactate dehydrogenase > upper limit of normal), and thrombocytopenia (platelets < lower limit of normal). Shiga toxin–producing *E. coli* infection (STEC-HUS) and hereditary or acquired complement dysregulation (atypical HUS) are two important causes of HUS and are the foci of this chapter.

SYNONYMS

HUS
STEC-HUS (Shiga toxin-producing *E. coli*-hemolytic uremic syndrome)
aHUS (atypical hemolytic uremic syndrome)
TMA (thrombotic microangiopathy)

ICD-10CM CODES
D59.3 Hemolytic-uremic syndrome
M31.1 Thrombotic microangiopathy

EPIDEMIOLOGY & DEMOGRAPHICS

Diarrhea-associated HUS, commonly due to STEC-HUS, is largely a disease of children and the most common etiology of HUS in children <5 yr of age. The incidence is estimated at 2 to 3 per 100,000 persons. It is more common in summer and fall months and in rural areas.

The incidence of atypical HUS (aHUS) is far less common, estimated at approximately 0.1 per million in children <17 yr of age and <0.5 per million in adults. The disease may be more common in adult women than men, without an apparent sex difference in pediatrics. Although germline mutations in the complement cascade are common, a positive family history is present in <30%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

In children with Shiga toxin–producing *E. coli*-hemolytic uremic syndrome (STEC-HUS), fever, abdominal pain, vomiting, and nonbloody diarrhea begin a median of 3 days after ingestion of infected material. Bloody diarrhea ensues 1 to 3 days later, and STEC-HUS typically develops within a wk of the onset of diarrhea. Fever is often absent at clinical presentation, and fatigue, dehydration, oliguria, and pallor are commonly presenting signs. Seizures can develop with severe disease. Leukocytosis is associated with a worse prognosis.

The onset of aHUS may be preceded by an identifiable "second hit" event such as infection or pregnancy in 50% of patients or fewer. Acute kidney injury is particularly severe in aHUS, with 70% to80% of patients requiring kidney replacement therapy (e.g., hemodialysis) shortly after presentation. The absence of severe AKI should prompt consideration of an alternative diagnosis. Thrombocytopenia is modest and often >60,000 cells/mm^3. Schistocytes may be present on peripheral blood smear, but are often fewer than expected. Notably, gastrointestinal symptoms may be present in 30% of patients, potentially mimicking STEC-HUS. Multi-organ system involvement with cardiovascular and neurological complications is common. C3 levels are low in approximately 50% of cases. Therefore, normal C3 concentration does not exclude aHUS. Proteinuria, potentially in the nephrotic range, and microscopic hematuria are frequently found.

ETIOLOGY

Endothelial activation and injury with subsequent microvascular thrombosis underlie the pathophysiology of HUS.

STEC-HUS is commonly attributed to ingestion of beef infected with the enterohemorrhagic O157:H7 strain of *E. coli*. However, non-O157 strains now account for approximately 50% of cases, and sources include contaminated water, milk, cider, fish, and vegetables. Endothelial injury is initiated by binding of Shiga toxin, followed by leukocyte recruitment, increased thrombin generation, impaired fibrinolysis, and small vessel thrombosis. Secondary activation of complement may contribute to endothelial injury early in the disease.

In aHUS, a germline mutation in the alternative pathway of complement or an acquired autoantibody directed against complement factor H is identified in 60% to 80% of patients. A second-hit, or "complement amplifying condition" (e.g., infection, pregnancy, inflammation), may be present. Endothelial injury results from the terminal membrane attack complex (C5b–9) and leukocyte recruitment, leading to activation of the coagulation system and small vessel thrombosis. The genes most commonly implicated in aHUS are complement factors H (CFH), I (CFI), and B (CFB); membrane cofactor protein (MCP); complement component 3 (C3); thrombomodulin (THBD); and complement factor H related protein 5 (CFHR5). Homozygous deletion of the gene region encompassing complement factor H-related protein 1 (CFHR1) is associated with the development of autoantibodies against factor H (FH). Mutations of the diacylglycerol kinase ε (DGKE) and methylmalonic aciduria cblC type with homocystinuria (MMACHC) genes cause aHUS. However, the roles of complement dysregulation in these disorders remains unclear.

DIAGNOSIS

Diagnosis requires recognition of the presence of a thrombotic microangiopathy associated with significant kidney injury. While STEC-HUS and aHUS are important causes, many other diseases have similar presentations (Table E1). In particular, thrombotic thrombocytopenic purpura (TTP) and infection by *S. pneumoniae* or human immunodeficiency virus (HIV) should be excluded. Severely depressed activity of ADAMTS13 (**a** **d**isintegrin **a**nd **m**etalloproteinase

TABLE E1 Differential Diagnosis of Etiologies of Hemolytic-Uremic Syndrome

ADAMTS13 Deficiency <5% to 10%	Drugs
Thrombotic thrombocytopenic purpura (TTP)	Quinine
Infection Associated	$P2Y_{12}$ antagonists
Shiga toxin–producing *E. coli*	Tacrolimus, cyclosporine A
Streptococcus pneumoniae	Sirolimus, everolimus
Campylobacter jejuni	Muromonab-CD3 (OKT3)
Human immunodeficiency virus	Gemcitabine
Cytomegalovirus	Mitomycin C
Epstein-Barr virus	Interferon
Influenza	Vascular endothelial growth factor inhibitors
Parvovirus B19	Tyrosine kinase inhibitors
Primary Abnormality in Complement Regulation	Cocaine
Atypical HUS	Oxymorphone
Immune Dysregulation	***Malignant Hypertension***
Monoclonal light chain	***Disseminated Intravascular Coagulation***
Systemic lupus erythematosus	***Pregnancy***

MMACHC gene mutation	***Other***
Diacylglycerol kinase ε gene mutation	Castleman disease
	POEMS
	Hemophagocytic lymphohistiocytosis (HLH)

HELLP, Hemolysis, elevated liver enzymes, and low platelet count; *HUS,* hemolytic uremic syndrome.

with a **t**hrombo**s**pondin type 1 motif, member **13**) on the order of <5% to 10% is consistent with TTP.

DIFFERENTIAL DIAGNOSIS

Diagnostic considerations are shown in Table E1. Occasionally, C3 glomerulopathy may demonstrate histology compatible with chronic microangiopathy. Typically, overt small vessel thrombosis is absent, and peripheral hemolysis is rarely present.

WORKUP

The workup for suspected HUS includes blood, urine, and stool testing.

LABORATORY TESTS

- Routine: Peripheral blood smear, lactate dehydrogenase level, haptoglobin level, prothrombin and partial thromboplastin times, fibrinogen, ADAMTS13 activity, C3 and C4 levels, complement CH50 test, direct antiglobulin test (i.e., Coombs), vitamin B_{12} level, methylmalonic acid level, and β-HCG (beta human chorionic gonadotropin) level
- Infection associated: Stool Shiga toxin assay, blood/urine/stool cultures, HIV antibody, and urine pneumococcal antigen if indicated
- Acquired: Antiphospholipid antibody testing (Russell viper venom time, β2-glycoprotein antibodies, anti-cardiolipin antibodies), ANA, serum free light chains, and FH autoantibody
- In-born: aHUS genetic testing

IMAGING STUDIES

There is no specific imaging study for HUS, and imaging should be performed as required for diseases under consideration.

Rx TREATMENT

The local health department should be notified if STEC is isolated; an epidemiological investigation may be required to prevent or mitigate a larger foodborne outbreak.

The mainstay of therapy for STEC-HUS is supportive care. Stabilization and maintenance of the extracellular fluid volume status is a major determinant of outcome, and patients should be aggressively but carefully volume resuscitated. Hypertension should be controlled. Antibiotics, especially fluoroquinolones, are generally contraindicated in STEC infection as they may precipitate HUS or worsen established disease. Plasma exchange and anti-complement C5 therapy (eculizumab) are not routinely recommended and have an unclear role in managing this disease. There is no established role for corticosteroids or anticoagulation.

The standard of care for aHUS is eculizumab. As aHUS is often a diagnosis of exclusion, it is important to promptly exclude other conditions for which treatment may differ (e.g., antibiotics for *S. pneumoniae* infection, plasma exchange for TTP). Plasma exchange may initially stabilize aHUS, but long-term outcomes of aHUS are poor when managed only with plasma exchange. Plasma exchange, however, may be initially beneficial in the setting of deficient levels of complement factors H, B, or I, or in the presence of FH autoantibody-associated disease. Hypertension should be managed with an angiotensin–converting enzyme inhibitor similar to scleroderma renal crisis. Kidney replacement therapy (e.g., hemodialysis) may be required.

Any clearly associated triggering condition should be addressed. For example, in gemcitabine-associated HUS, the drug should be discontinued if feasible.

OUTCOME

The vast majority of pediatric patients with STEC-HUS recover. Death occurs in approximately 3% of afflicted individuals. In survivors, albuminuria develops in 20% to 40%, abnormal kidney function in 10% to 20%, and hypertension in 5% to 15%.

Historically, in aHUS, 40% to 60% of plasma exchange–treated patients either died or developed end-stage renal disease by 1 yr. With eculizumab, mortality is low, 50% develop chronic kidney disease, and 3% to 10% have cardiovascular complications. Approximately 80% of patients requiring hemodialysis regain sufficient kidney function to discontinue kidney replacement therapy. Many patients are able to withdraw eculizumab treatment under expert guidance. Most forms of aHUS may recur in the transplanted kidney.

PEARLS & CONSIDERATIONS

- STEC-HUS is the most common cause of HUS in children, although many different infectious and other etiologies exist.
- aHUS is more common than STEC-HUS in adults, but etiologies such as TTP, infection, antiphospholipid antibody syndrome, and others must be excluded.
- Prompt diagnosis and treatment is necessary to reduce morbidity and mortality.
- Immediate nephrology and hematology consultations are recommended.

BASIC INFORMATION

DEFINITION

Hemophilia is a hereditary bleeding disorder caused by low levels of factor VIII (hemophilia A) or factor IX coagulant activity (hemophilia B).

SYNONYMS

Hemophilia A: Classic hemophilia, factor VIII deficiency hemophilia
Hemophilia B: Christmas disease, factor IX hemophilia

ICD-10CM CODES	
D66	Hereditary factor VIII deficiency
D67	Hereditary factor IX deficiency
D68.311	Acquired hemophilia
Z14.01	Asymptomatic hemophilia A carrier
Z14.02	Symptomatic hemophilia A carrier

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE/PREVALENCE (IN U.S.): Hemophilia A: 100 cases per 1 million males; it is the most common severe inherited bleeding disorder in humans. Hemophilia B: 20 cases per 1 million males. There are approximately 400,000 patients with severe hemophilia worldwide.
GENETIC: Both hemophilias have an X-linked recessive pattern of inheritance with only males affected.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The clinical features of hemophilia A and B are generally indistinguishable from each other. The clinical symptoms are determined by the baseline factor activity in each patient. Spontaneous bleeding can occur with those with *severe* hemophilia (<1% factor VIII or IX activity). Trauma-induced bleeding can occur in those with *moderate* hemophilia (factor levels 1% to 5%) and *mild* hemophilia (factor levels >5%).
- Bleeding is most commonly seen in joints (knees, ankles, elbows), resulting in hot, swollen, painful joints (Fig. E1) and subsequent crippling joint deformity (Fig. E2).
- Bleeding can also occur into the muscles and the gastrointestinal tract.
- Compartment syndrome can occur from large hematomas.
- Hematuria may be present.

ETIOLOGY

- Both disorders are congenital X-linked recessive disorders of hemostasis. An overview of the coagulation cascade relevant to hemophilia and von Willebrand disease (vWD) is provided in Fig. E3.
- Hemophilia A: Low factor VIII coagulant (VIII:C) activity; can be classified as mild if factor VIII:C levels are >5%, moderate if levels are 1% to 5%, and severe if levels are <1%.
- Hemophilia B: Low levels of factor IX coagulant activity.
- Spontaneous acquisition of factor VIII inhibitors (acquired hemophilia) is rare.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other clotting factor deficiencies
- Platelet function disorders
- Vitamin K deficiency

WORKUP

Patients with mild hemophilia bleed only in response to major trauma or surgery and may not be diagnosed until young adulthood. Diagnostic workup includes laboratory evaluation, as below:

- Partial thromboplastin time (aPTT) is prolonged. Prothrombin time (PT) is normal, and the aPTT mixing study will fully correct.
- Factor VIII (Table E1) reduced factor VIII:C level distinguishes hemophilia A from other causes of prolonged PTT.
- Factor VIII antigen, fibrinogen level, and bleeding time are normal.
- Factor IX coagulant activity levels are reduced in patients with hemophilia B.
- Coagulation factor activity measurement is useful to correlate with disease severity. Normal range is 50 to 150 U/dl; 5 to 20 U/dl indicates mild disease, 2 to 5 U/dl indicates moderate disease, and <2 U/dl indicates severe disease with spontaneous bleeding episodes.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of contact sports
- Patient education regarding the disease; promotion of exercises such as swimming
- Avoidance of aspirin or other NSAIDs
- Orthopedic evaluation and physical therapy evaluation in patients with joint involvement
- Hepatitis vaccination

ACUTE GENERAL Rx

(*See* Box E1, Box E2)

HEMOPHILIA A:

- Reversal and prevention of acute bleeding in hemophilia A and B are based on adequate replacement of deficient or missing factor protein. Table E2 summarizes recommendations for clotting factor replacement.
- The choice of the product for replacement therapy is guided by availability, capacity, concerns, and cost. Recombinant factors cost two to three times as much as plasma-derived factors, and the limited capacity to produce recombinant factors often results in periods of shortage. In the United States, the majority of patients with severe hemophilia use recombinant products.
- Factor VIII concentrates are effective in controlling spontaneous and traumatic hemorrhage in severe hemophilia. The new recombinant factor VIII is stable without added human serum albumin (decreased risk of transmission of infectious agents).
- Emicizumab is a bispecific monoclonal antibody that bridges activated factor IX and factor X to replace the function of missing activated factor VIII, thereby restoring

FIG. E1 Acute hemarthrosis of the knee is a common complication of hemophilia. It may be confused with acute infection unless the patient's coagulation disorder is known because the knee is hot, red, swollen, and painful. (From Forbes CD, Jackson WF: *Color atlas and text of clinical medicine,* ed 3, London, 2003, Mosby.)

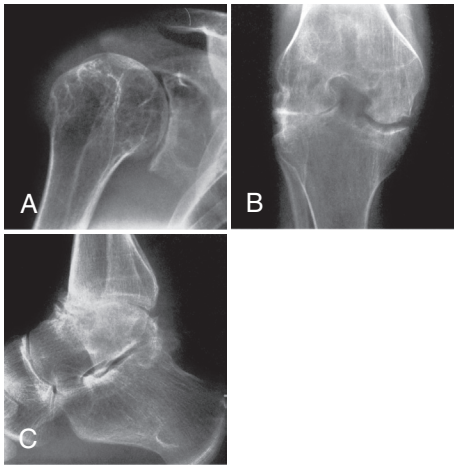

FIG. E2 Radiographic changes associated with hemophilic arthropathy. A, Radiograph of the shoulder showing multiple subchondral cysts in the head of the humerus, an early finding in hemophilic arthropathy. The glenohumeral joint space is fairly well preserved, and range of motion is normal. **B,** Widening of the intercondylar notch and near fusion of the femur and medial tibial condyle in the knee joint affected by hemophilic arthropathy. **C,** Narrowing and fusion of the tibiotalar joint in the ankle. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 5, Philadelphia, 2009, Churchill Livingstone.)

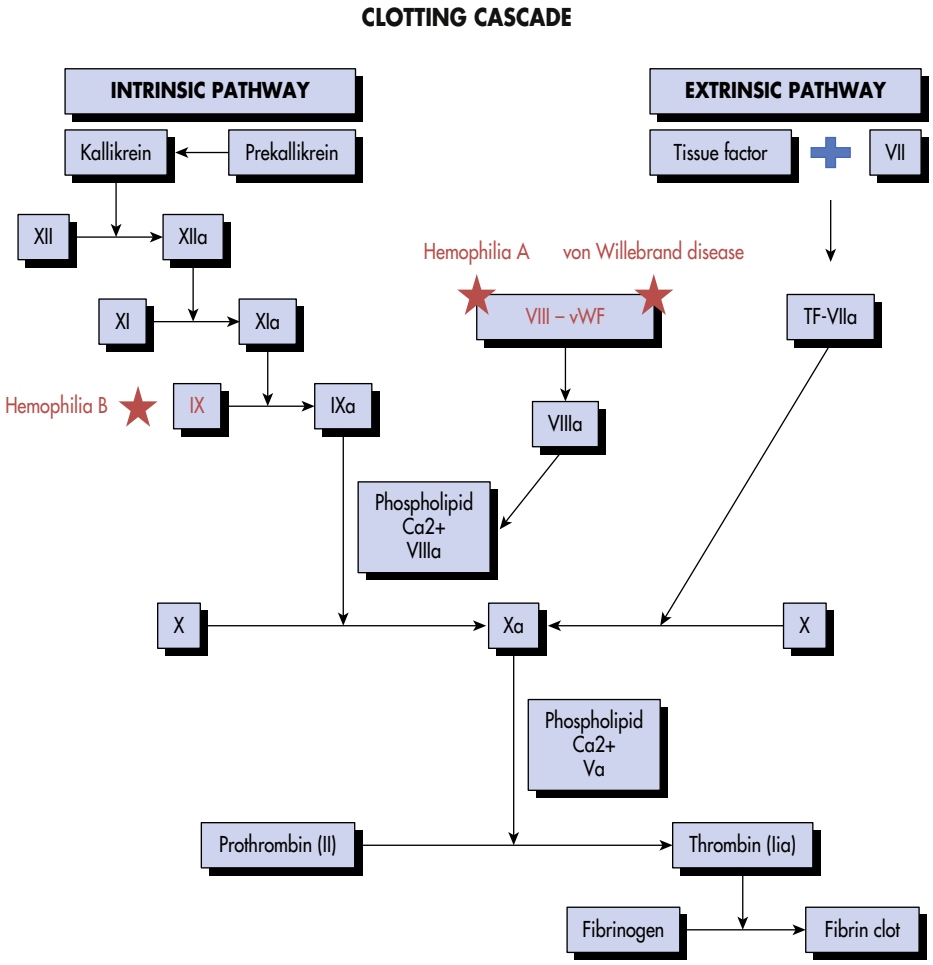

FIG. E3 Factor VIII in plasma is mostly noncovalently bound to von Willebrand factor *(vWF),* which protects it from metabolism. A number of factors including thrombin act to dissociate VIII from vWF to provide cofactors for the conversion of X to Xa. An absolute deficiency in VIII, a functional change, or a deficiency in vWF will result in reduced VIIIa to act as a cofactor. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

TABLE E1 Differential Diagnosis of a Low Factor VIII Level

- FVIII <10%
  1. Severe or moderately severe hemophilia A
  2. Severe type 1 VWD
  3. Type 3 VWD

  5. Acquired hemophilia A
  6. Acquired VWD
- FVIII: 10% to 50%
  1. Mild hemophilia A
  2. Type 1 VWD
  3. Type 2N VWD
  4. Combined FVIII and FV deficiency

FV, Factor V; *FVIII,* factor VIII; *VWD,* von Willebrand disease. (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

hemostasis. Emicizumab prophylaxis administered subcutaneously once weekly or every 2 weeks led to a significantly lower bleeding rate than no prophylaxis among persons with hemophilia A without inhibitors; emicizumab is not recommended for treatment of bleeding.

- Alloantibodies (inhibitors) that neutralize factor VIII clotting function occur in nearly 30% of patients with severe hemophilia A after exposure to factor VIII. In these patients, bypassing agents (antiinhibitor coagulant complex [AICC] and recombinant activated factor VII [rFVIIa]) can be used to treat bleeding. AICC can also be used prophylactically to decrease the frequency of joint and other bleeding events in patients with severe hemophilia A and factor VIII inhibitors. Trials with emicizumab have shown that prophylaxis with it significantly lowers the rate of bleeding events among patients with hemophilia A who have developed inhibitors.
- Recombinant activated factor VII is useful to stop spontaneous hemorrhages and prevent excessive bleeding during surgery in 75% of patients with inhibitors. Recommended dose is 90 μg/mg of body weight every 2 to 3 hr for treatment of life-threatening hemorrhage.
- Desmopressin acetate 0.3 μg/kg q24h (causes release of factor VIII:C) may be used in preparation for minor surgical procedures in mild hemophiliacs.
- Aminocaproic acid (EACA, Amicar) 4 g PO q4h can be given for persistent bleeding that is unresponsive to factor VIII concentrate or desmopressin.
- *Valoctocogene roxaparvovec is an investigational adeno-associated virus vector containing the B-domain-deleted FVIII gene. The 3-yr follow-up results from an ongoing phase I/II study of patients with severe hemophilia A showed significantly reduced annual bleeding rates and increased factor VIII (FVIII) activity levels. This therapy is awaiting approval from regulatory agencies.*

HEMOPHILIA B:

- Infuse factor IX concentrates. It is important to remember that factor IX concentrates contain other proteins that may increase the risk of thrombosis with recurrent use; thus factor IX concentrates must be used only when clearly indicated.
- Daily administration of oral cyclophosphamide and prednisone without empirical factor VIII therapy is an effective and well-tolerated treatment for acquired hemophilia.

BOX E1 Treatment Options for Bleeding in a Patient with Factor VIII Deficiency and an Inhibitor

- Low Titer, Low Responder
- Mild Bleeding
  1. Local and conservative measures, such as rest, ice, compression, and elevation
  2. If the patient is known to respond to DDAVP (i.e., mild hemophilia A), 0.3 μg/kg IV or 300 μg intranasal (150 μg per nostril; 150 μg for patients <50 kg) for minor bleeding or treatment before minor surgery
  3. Oral antifibrinolytic therapy (ε-aminocaproic acid or tranexamic acid) for mucosal bleeding
  4. FVIII dosing to raise the level to 50%
  5. Recombinant FVIIa (90 to 120 μg/kg, followed by 90 μg/kg every 2 to 3 hours)
  6. Activated prothrombin complex concentrates (50 to 100 units/kg, with maximum daily dose of 200 units/kg)
  7. Concurrent treatment with antifibrinolytics should be administered with caution
- Life- or Limb-Threatening Bleeding
  1. FVIII dosing to maintain FVIII activity levels at 100%
  2. Recombinant FVIIa (270 μg/kg for one dose may be considered with caution versus 90 μg/kg every 2 to 3 hours)
  3. Activated prothrombin complex concentrates (100 units/kg, with maximum daily dose of 200 units/kg)
  4. Concurrent treatment with antifibrinolytics should be administered with caution
- Low Titer, High Responder
- Mild Bleeding
  1. Local and conservative measures, such as rest, ice, compression, and elevation
  2. If the patient is known to respond to DDAVP (i.e., mild hemophilia A), 0.3 μg/kg IV or 300 μg intranasal (150 μg for patients <50 kg) for minor bleeding or treatment before minor surgery
  3. Oral antifibrinolytic therapy (ε-aminocaproic acid or tranexamic acid) for mucosal bleeding
  4. Recombinant factor VIIa (270 μg/kg, bolus may be considered with caution versus 90 μg/kg every 2 to 3 hours)
  5. Activated prothrombin complex concentrates (100 units/kg, with a maximum daily dose of 200 units/kg, may induce anamnesis)
- Life- or Limb-Threatening Bleeding
  1. FVIII in high doses to maintain levels of 100%
  2. Frequent monitoring for an anamnestic response, usually within 5 to 7 days
  3. After the anamnestic response develops:
     a. Recombinant FVIIa (270 μg/kg, may be considered with caution versus 90 μg/kg every 2 to 3 hours)
     b. Activated prothrombin complex concentrates (50 to 100 units/kg, with a maximum daily dose of 200 units/kg)
- High Titer, High Responder
- Mild Bleeding
  1. Local and conservative measures, such as rest, ice, compression, and elevation
  2. Oral antifibrinolytic therapy (ε-aminocaproic acid or tranexamic acid) for mucosal bleeding
  3. Recombinant FVIIa (270 μg/kg, should be considered with caution versus 90 μg/kg every 2 to 3 hours)
  4. Activated prothrombin complex concentrates (100 units/kg, with a maximum daily dose of 200 units/kg)
  5. Concurrent treatment with antifibrinolytics should be administered with caution
- Life- or Limb-Threatening Bleeding
  1. Recombinant FVIIa (270 μg/kg, should be considered with caution versus 90 μg/kg IV every 2 to 3 hours)
  2. Activated prothrombin complex concentrates (100 units/kg, with a maximum daily dose of 200 units/kg)
  3. If available, immunoadsorption can be attempted to rapidly lower the inhibitor titer so as to allow use of FVIII
- Main Features of the Agents Effective for Inhibitor Treatment/Prophylaxis
  1. **Content** APCC: Activated vitamin k–dependent clotting factors; rFVIIa: Recombinant FVIIa alone
  2. **Mechanism of action** APCC: Activate plasma FX and FII; rFVIIa: Activates FX on platelets
  3. **Half-Life** APCC: Putatively 8 to 12 hours; rFVIIa: 2 to 3 hours
  4. **Efficacy** APCC: About 80%; rFVIIa: About 80%

APCC, activated prothrombin complex concentrate; *DDAVP,* desmopressin acetate; *FII,* factor II; *FIII,* factor III; *FVIIa,* activated factor VIIa; *FX,* factor X; *IV,* intravenous; *rFVIIa,* recombinant activated clotting factor VII.
(From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

CHRONIC Rx

- The aim of chronic treatment is to prevent spontaneous bleeding and excessive bleeding during any surgical intervention. Monitoring and treatment of patients with hemophilia at comprehensive hemophilia treatment centers is cost-effective and decreases morbidity and mortality.
- Prophylaxis with recombinant factor VIII can prevent joint damage and decrease the frequency of joint and other hemorrhages in young boys with severe hemophilia A. The estimated annual cost for treatment of one patient with recombinant factor VIII is $300,000.
- Implantation of genetically altered fibroblasts that produce factor VIII is safe and well tolerated. This form of therapy is feasible in patients with severe hemophilia. Hemophilia will likely be the first common, severe genetic disease to be cured by gene therapy.
- Table E3 summarizes alternative, nonclotting factor concentrate therapies for treating hemophilia.

DISPOSITION

- In the 1980s, approximately 90% of patients with hemophilia were infected with the hepatitis C virus (HCV), and more than 55% of this cohort was coinfected with HIV. The development of genetically engineered recombinant factor therapy in the 1990s virtually eliminated the risk of acquiring HCV and HIV from factor replacement therapy.
- Despite the advent of virally safe blood products and blood treatment programs, many hemophiliacs are HCV and HIV seropositive.
- Intracranial bleeds are a common cause of death in hemophiliacs. They are fatal in 30% of patients, occur in 10% of patients, and are generally the result of trauma.

REFERRAL

To a specialized center with multidisciplinary teams that can treat the disease and comorbidities

Hemophilia (Patient Information)

AUTHOR: **Bharti Rathore, MD**

BOX E2 Treatment of Life-Threatening Bleeding Episodes in Patients with Inhibitors Against Factor VIII or Factor IX

Concentrates
- Factor VIII containing concentrates in high doses (as high as 150-200 IU/kg) if inhibitor titer is low (<5-10 BU). High-dose continuous infusion of factor VIII (≈10 IU/kg per hour) after a high-dose bolus may be useful.
- Recombinant factor VIIa. Dose is 90 μg/kg (or a dose up to 320 μg/kg) administered every 2 hours. Risk of thrombosis exists with this product.
- Activated PCCs at a dose of 50-75 IU/kg every 8-12 hours. Risk of thrombosis exists with this product.

Immunomodulation
- Antibody depletion
  1. Plasmapheresis
  2. Extracorporeal immunoadsorption of plasma (staphylococcal protein A column therapy and other methods)
- Suppression of antibody production
  1. High-dose steroids (equivalent of prednisone 80 mg/day)
  2. Cyclophosphamide (10-15 mg/kg load and 2-3 mg/kg per day)
  3. Intravenous immunoglobulin (1 g/kg daily for 2 days)
  4. More aggressive regimens that may include vincristine, azathioprine, cyclosporine, or interferon-γ

Conservative Measures
- Immobilization
- Compression
- Local application of hemostatic agents
- Antifibrinolytics
- Avoid venipunctures, intramuscular injections, arterial puncture, and lumbar punctures
- Avoid use of medications that inhibit platelet function (ASA, NSAIDs)
- DDAVP may be effective in some patients with low-titer inhibitors

ASA, Aspirin; *BU,* Bethesda unit; *DDAVP,* desmopressin acetate; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PCC,* prothrombin complex concentrate.
(From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

TABLE E2 Recommendations for Clotting Factor Replacement

Site of Bleed	Level Desired (%)	Hemophilia A (rFVIII) (U/kg)	Hemophilia B (rFIX) (U/kg)
Oral mucosa	>30	20	40
Epistaxis	>30	20	40
Joint or muscle	>50	30	50
GI	>50	30	50
GU	>50	50	75
CNS	>100	75	125
Trauma or surgery	>100	75	125

CNS, Central nervous system; *GI,* gastrointestinal; *GU,* genitourinary; *rFIX,* recombinant factor IX; *rFVIII,* recombinant factor VIII.
(From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

TABLE E3 Alternative, Nonclotting Factor Concentrate Therapies for Treating Hemophilia

- Rebalancing hemostasis strategies:
- TFPI Inhibition approaches: Anti-TFPI aptamer, antibody and peptide.
- Antithrombin siRNA biosynthesis inhibition.
- Both approaches can be delivered by infrequent (weekly or less often) subcutaneous injections.
- Factor VIII mimetic molecule: Bispecific antibody to FIXa and FX.
- Can be administered by subcutaneous injection and has shown activity in FVIII inhibitor patients.

FX, Factor X; *FIXa,* Factor IXa; *FVIII,* factor VIII; *siRNA,* small interfering ribonucleic acid; *TFPI,* tissue factor pathway inhibitor.
(From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

BASIC INFORMATION

DEFINITION

Hemoptysis is coughing up of blood originating from the lower respiratory tract, ranging from blood-streaked sputum to gross blood. If greater than 400 to 600 ml in 24 hours or if the bleeding rate is >100 ml/hr, it is considered massive hemoptysis.

ICD-10CM CODE
R04.2 Hemoptysis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown, varies based on underlying pathology
RISK FACTORS: Tobacco smoking predisposes to lung cancer, a common cause of hemoptysis. Systemic processes (rheumatologic, renal, hematologic) may contribute to alveolar hemorrhage or vasculitis. Anticoagulation can worsen bleeding.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presentation of hemoptysis is variable (Table 1) and can range from minimal blood-tinged sputum to more than 500 ml of gross blood in 24 hr. Other symptoms depend on the underlying etiology and can include cough, sputum production, fever, shortness of breath, weight loss, night sweats, wheezing, and chest pain.
- There are no specific exam findings, but clues to the etiology may be present, for example, focal wheezing, rhonchi or rales on pulmonary exam, murmur of mitral stenosis on cardiac exam.

ETIOLOGY

- There are many potential causes of hemoptysis including airway disease (bronchitis, bronchiectasis, lung neoplasm), infection (necrotizing pneumonia, lung abscess, tuberculosis, fungal infection), inflammatory diseases (granulomatosis with polyangiitis, Goodpasture syndrome, lupus), cardiac disease (mitral stenosis after rheumatic heart disease, congenital heart diseases), and others (pulmonary embolism, cocaine use, foreign body, airway trauma, iatrogenic and cryptogenic).
- Acute respiratory tract infections, asthma, chronic obstructive pulmonary disease (COPD), malignancy, and bronchiectasis are the most common diagnoses in outpatient primary care.
- Worldwide, tuberculosis accounts for 7% to 85% of cases of massive hemoptysis. Highest incidence is in South Africa; lowest incidence is in the U.S.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Various potential causes of lower respiratory tract bleeding
  1. Airway disease (bronchitis, bronchiectasis, lung neoplasm)
  2. Infection (necrotizing pneumonia, lung abscess, tuberculosis, fungal infection)
  3. Inflammatory diseases (granulomatosis with polyangiitis, Goodpasture syndrome, lupus)
  4. Cardiac disease (mitral stenosis after rheumatic heart disease, congenital heart diseases)
  5. Pulmonary embolism
  6. Cocaine use
  7. Foreign body
- Bleeding from upper respiratory tract
- Hematemesis or epistaxis
- Coagulopathy

WORKUP

- The initial history should focus on determining the anatomic origin of the bleeding and on quantifying the volume of the hemoptysis in order to triage appropriately.
- Complete history and physical exam may suggest a particular etiology; important to ask about duration and quantity of hemoptysis and smoking history.

LABORATORY TESTS

- Complete blood count
- Coagulation profile
- Serum chemistries, including creatinine, urinalysis
- If indicated, consider vasculitis serologies (i.e., antinuclear antibody [ANA], antineutrophil cytoplasmic antibodies [ANCA], anti-glomerular basement membrane [anti-GBM])
- Arterial blood gas to assess oxygenation
- Sputum for cultures and cytologic studies
- Purified protein derivative (PPD)

IMAGING STUDIES

- Chest x-ray: All patients with hemoptysis should have a chest x-ray but will likely need additional studies to localize site of bleeding.
- Chest CT: Chest CT scan combined with flexible bronchoscopy has the highest yield for localizing the site of bleeding.

TABLE 1 Features of Hemoptysis and Patient Presentation

Hemoptysis Feature	Clinical Presentation
Blood usually bright red	Often dyspneic
Portion of blood usually frothy	Hypoxemia
Alkaline pH	
Blood usually mixed with sputum	Preceding cough common
Alveolar macrophages may be present in sputum smear	Anemia and melena uncommon

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

TREATMENT

Varies based on underlying etiology and nonmassive versus massive hemoptysis

NONPHARMACOLOGIC THERAPY

Massive hemoptysis:
- Arteriographic embolization of bronchial arteries and/or collateral systemic vessels
- Surgical resection of affected lung

ACUTE GENERAL Rx

Massive hemoptysis (Fig. 1):
- Stabilize hemodynamic status and oxygenation.
- Reverse any coagulopathy.
- Bronchoscopy can be used to identify cause of hemoptysis (e.g., neoplasm), as well as to help isolate a site/segment of bleeding.
- If site of bleeding is known, place patient with bleeding lung in dependent position to prevent blood from spilling into nonaffected lung, and consider selective intubation with large-bore, single-lumen endotracheal tube or double-lumen endotracheal tube.
- Bronchoscopic lavage with iced saline or topical application of epinephrine can be tried as a temporizing measure.
- Bronchoscopic balloon tamponade of bleeding site can be used as temporizing measure.
- Early consultation with interventional radiology, interventional pulmonology, and/or thoracic surgery for definitive intervention is recommended.

Submassive hemoptysis:
- For submassive hemoptysis, identify and treat underlying condition. Refer to pulmonologist or hematologist if indicated.

CHRONIC Rx

For patients requiring anticoagulation or antiplatelet therapy for another disorder, consider risks/benefits of continued anticoagulation or antiplatelet therapy.

DISPOSITION

Generally, patients have a good prognosis after an episode of hemoptysis, but those with massive bleeding and/or malignancy tend to have a poorer prognosis.

BASIC INFORMATION

DEFINITION

A hemorrhoid is a varicose dilation of a vein of the superior or inferior hemorrhoidal plexus, resulting from a persistent increase in venous pressure. External hemorrhoids are distal to the pectinate or dentate line (inferior plexus), are covered in stratified squamous epithelium, and have sensory innervation. Internal hemorrhoids are proximal to the pectinate or dentate line (superior plexus), are covered in columnar epithelium, and do not have sensory innervation. Mixed hemorrhoids are located both distal and proximal to the dentate line. Internal hemorrhoids can prolapse to various degrees, and both internal and external hemorrhoids can thrombose.

SYNONYM

Piles

ICD-10CM CODES

K64.0 First degree hemorrhoids
K64.1 Second degree hemorrhoids
K64.2 Third degree hemorrhoids
K64.3 Fourth degree hemorrhoids
K64.8 Other hemorrhoids
K64.9 Unspecified hemorrhoids

EPIDEMIOLOGY & DEMOGRAPHICS

Potential for development of symptomatic hemorrhoids in all adults

PREVALENCE:

- Self-reported prevalence in the U.S. is around 5% of the general population, with 50% of the population reported experiencing them within their lifetime
- Hemorrhoids are identified in nearly 40% of patients undergoing screening colonoscopy.
- Increased predominance in white and higher socioeconomic populations

PREDOMINANT SEX: Males and females affected equally

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- 40% of individuals are asymptomatic
- Painless bleeding with defecation; bleeding is bright red with staining seen on toilet paper or droplets in toilet (most common complaint in those who are symptomatic)
- Pressure in the perianal area
- Perianal irritation
- Mucofecal staining of underclothes
- Fecal incontinence
- Acute external hemorrhoids: Painful, swollen, and often thrombosed; red, deep purple tense bulge; can become necrotic or infected (Fig. E1)
- Pain on sitting, standing, or defecating often associated with thrombosed hemorrhoid
- Prolapse (Fig. E2)
- Constipation
- A classification of internal hemorrhoids is described in Table E1

ETIOLOGY

- Low-fiber, high-fat diet
- Chronic constipation and straining with defecation
- Diarrhea
- Advancing age
- High resting anal sphincter pressures
- Pregnancy
- Obesity
- Rectal surgery (i.e., episiotomy)
- Prolonged sitting
- Anal intercourse
- Pelvic tumors

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fissure
- Abscess
- Anal fistula
- Condylomata acuminata
- Hypertrophied anal papillae
- Rectal prolapse (Fig. E3)
- Rectal polyp
- Neoplasm (anal cancer, colorectal cancer)
- Inflammatory bowel disease

WORKUP

- Inspection
- Digital rectal examination: At rest and with Valsalva
- Anoscopy
- Endoscopy (dependent on age and associated symptoms)

TABLE E1 Classification of Internal Hemorrhoids

Grade	Location	Symptoms
1	Bulge into anal canal	Painless bleeding
2	Prolapse, reduce spontaneously	Bleeding, burning, itching
3	Prolapse, must be manually reduced	Bleeding, itching, mucoid drainage
4	Prolapse and cannot be reduced	Pain, bleeding, mucoid drainage

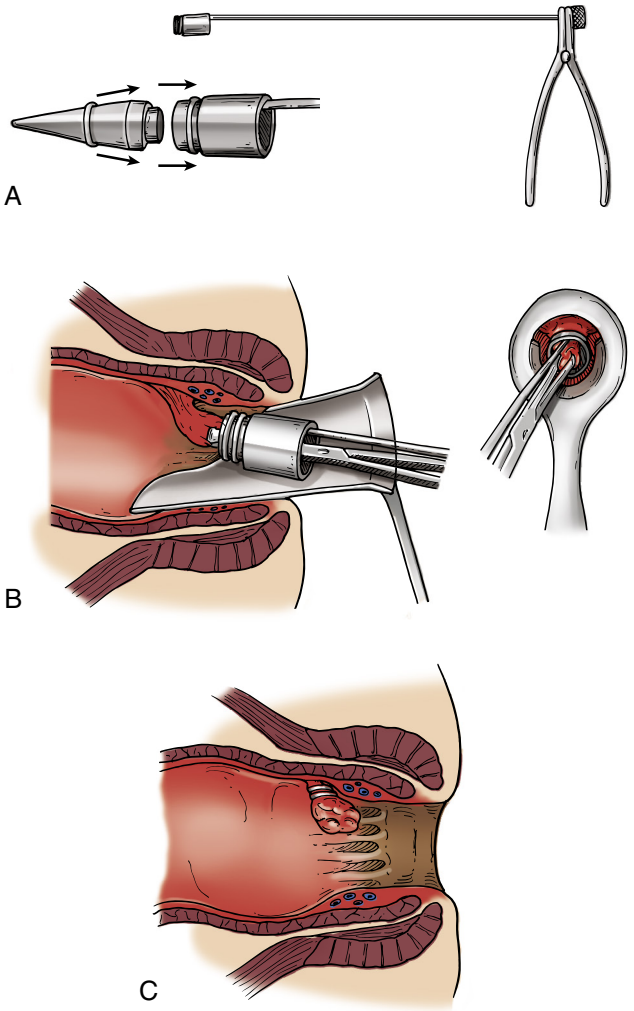

FIG. E4 Rubber band ligation of internal hemorrhoids. A, Rubber band placed onto banding gun. **B,** Hemorrhoid is grasped 2 cm above the dentate line and the band advanced over the hemorrhoid. **C,** Band in correct position after ligation. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of constipation and straining with defecation
- Avoidance of prolonged sitting on toilet (consider decreased screen time on toilet)
- High-fiber diet (20 to 30 g/day)
- Increased fluid intake (six to eight glasses of water per day)
- Exercise
- Cleaning with mild soap and water after defecation
- Warm soaks (15 min TID and after defecation) or ice to soothe
- Sitz baths

ACUTE GENERAL Rx

- Fiber supplements to provide bulk (psyllium extracts or mucilloids)
- Medicated compresses with witch hazel
- Topical hydrocortisone (1% to 3% cream or ointment)
- Topical anesthetic (lidocaine)
- Glycerin suppositories
- Stool softeners
- Surgically remove during first 72 hr after onset

CHRONIC Rx

- Rubber band ligation (Fig. E4)
- Injection sclerotherapy
- Photocoagulation
- Cryodestruction
- Hemorrhoidectomy
- Fig. E5 illustrates the technique for excision of thrombosed external hemorrhoids. Fig. E6 illustrates the anatomy of the rectosigmoid region
- Anal dilation
- Laser (Fig. E7) or cautery hemorrhoidectomy
- Observance for complications: Thrombosis, bleeding, infection, anal stenosis, or weakness
- Stapled hemorrhoidopexy, a newer technique for the treatment of patients with Grade III or IV internal disease, involves the use of a circular stapler to resect mucosal tissue, interrupt arterial and venous flow, and simultaneously affix the remaining tissue in situ about the dentate line[1]
- Table E2 summarizes treatment options for internal hemorrhoids

DISPOSITION

Should resolve, but high rate of recurrence

REFERRAL

To colorectal or general surgeon for any hemorrhoid that does not respond to conservative therapy

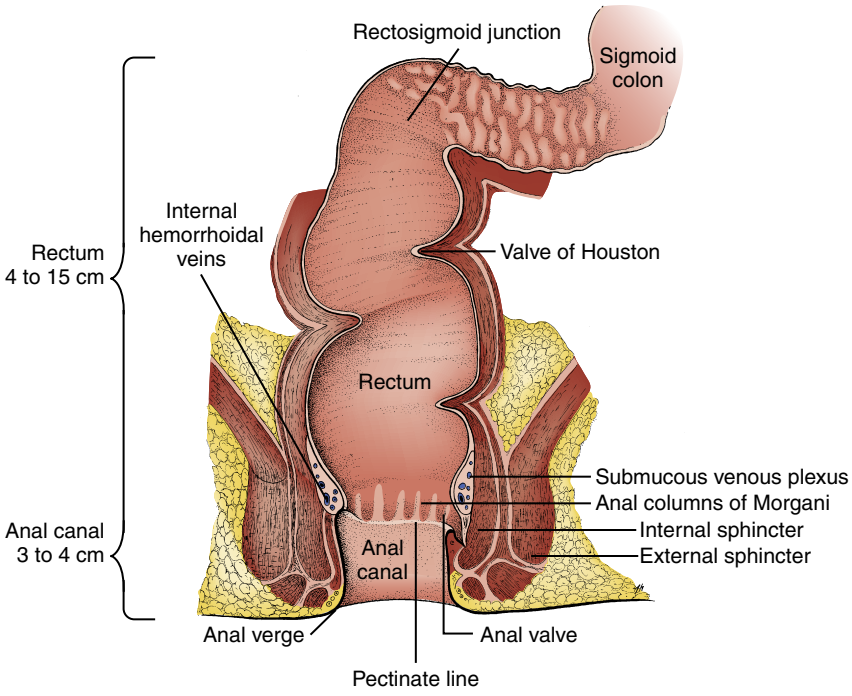

FIG. E6 Anatomy of the retrosigmoid region. (From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.)

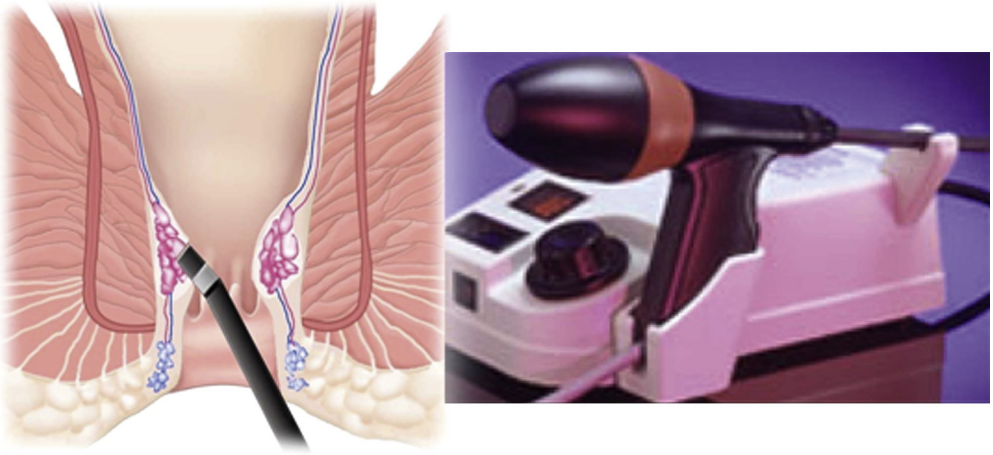

FIG. E7 Ferguson hemorrhoidectomy. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

TABLE E2 Treatment Options for Internal Hemorrhoids

Type of Treatment	Hemorrhoid Grades	Success Rate	Comments
General			
Diet (increase in fiber and fluids) and bowel habit modification	1-4	Unknown	Patients with all grades of hemorrhoids should use these measures (see text). Patients with high grades of hemorrhoids will need additional therapy.
Endoscopic			
Sclerosing agent	1-4	75%	May be the favored treatment of patients with AIDS (successful results even with grades 3 and 4 hemorrhoids). Life-threatening sepsis rarely complicates therapy.
Rubber band ligation	2 and 3	65%-75%	Grade 1 hemorrhoids are too small, and grade 4 hemorrhoids are usually too large for this procedure. The most commonly performed office procedure for hemorrhoids Life-threatening sepsis rarely complicates therapy; 1% risk of severe hemorrhage when band sloughs.
Infrared coagulation	1 and 2	Less than for rubber band ligation	Equipment for the procedure is expensive. Rare complications
Surgical			
Excisional hemorrhoidectomy	3 and 4	>85% on 10-yr follow-up	External tags may be removed at the time of the surgical procedure. Postoperative pain is pronounced.
Procedure for prolapsing hemorrhoids (PPH)*	3 and 4	>75%; several studies show higher long-term recurrence rates than with excisional hemorrhoidectomy	Newer procedure Overall, significantly less postoperative pain than with excisional hemorrhoidectomy, but some patients experience severe, persistent postoperative pain or defecation urgency Pelvic sepsis and death have been reported after this procedure.

AIDS, Acquired immune deficiency syndrome.
*Also called *stapled hemorrhoidopexy.*
(From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

PEARLS & CONSIDERATIONS

COMMENTS

- Patients need to understand the importance of a healthy diet, regular exercise, and rectal hygiene.
- Stress the importance of avoiding prolonged sitting and straining on the toilet.
- Stress the need not to defer the urge to defecate.
- Surgical treatment with excisional hemorrhoidectomy recommended within 24 to 72 hours of initial symptoms of thrombosed hemorrhoid.
- Patients with red flag symptoms such as melena, dark blood from the rectum, constitutional symptoms, change in bowel habits, and fecal occult blood positive stools without gross blood per rectum require further investigation with endoscopy and referral as necessary.

Heparin-Induced Thrombocytopenia

BASIC INFORMATION

DEFINITION

There are two forms of heparin-induced thrombocytopenia (HIT). Type I HIT is a mild, transient decrease in platelet count that occurs during the first 2 days of heparin exposure due to non–immune-mediated platelet aggregation. This is a benign reaction, and the platelet count will return to normal while heparin is continued. This chapter will address Type II HIT, an antibody-mediated thrombocytopenia with risk of thrombosis.

SYNONYMS

Type II heparin-induced thrombocytopenia
Heparin-induced thrombocytopenia and thrombosis (HITT)
Heparin-associated immune thrombocytopenia

ICD-10CM CODE
D75.82 Heparin-induced thrombocytopenia (HIT)

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Occurs in 0.2% to 5% of patients exposed to heparin in various clinical settings. Initially, there was an overwhelming underdiagnosis of HIT; however, since the introduction of HIT antibody ELISA test, there is a propensity to overdiagnose HIT irrespective of the clinical scenario.
PREDOMINANT SEX AND AGE: Females are at slightly higher risk than males. More common in adults, but may also occur in children.
RISK FACTORS: Heparin type (unfractionated heparin has up to 10 times greater risk than low–molecular-weight heparin), dose (therapeutic dose may have a greater risk than prophylactic dose, though no dose is considered too low to cause HIT), and duration (longer duration of exposure confers greater risk); type of patient (surgical patients, especially cardiac and orthopedic, are at higher risk than medical patients). Risk factors for HIT are summarized in Table 1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Suspect in a patient with:
- Exposure to heparin in the last 5 to 10 days OR exposed to heparin in the prior 3 mo
- Unexplained platelet count decrease to 50% below pretreatment baseline
- Onset of thrombocytopenia 5 to 10 days after heparin initiation
- Venous or arterial thrombosis (e.g., DVT or phlegmasia cerulea dolens, pulmonary embolism, skin necrosis at heparin injection sites, limb gangrene, adrenal hemorrhage, stroke or cavernous sinus thrombosis, myocardial infarction)
- Acute anaphylaxis during administration of heparin bolus

ETIOLOGY

Occurs when IgG antibodies bind to complexes of heparin and platelet factor 4 (PF4), a prothrombotic cytokine released from platelets during their activation. The resulting immune complexes activate adjacent platelets, leading to further PF4 release, additional antibody production, and eventual platelet aggregation with premature removal from circulation (causing thrombocytopenia). This process also leads to increased thrombin generation, though the full mechanism of thrombosis in HIT is not completely understood.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Thrombocytopenia due to other causes including:
- Sepsis or infection
- Disseminated intravascular coagulation
- Immune thrombocytopenia
- Thrombocytopenic thrombotic purpura
- Hemolytic uremic syndrome
- Drug-induced thrombocytopenia (other than heparin)
- Antiphospholipid antibody syndrome
- Liver failure
- Splenic sequestration
- Intravascular devices

WORKUP

HIT is, first and foremost, a clinical diagnosis that is confirmed with laboratory testing. See Table 2 for workup based on pretest probability. If the patient has a low pretest probability score, heparin can be safely continued, and there is no need to send further testing for HIT. A patient with moderate-to-high pretest probability requires HIT testing (Table 3), imaging studies for lower-extremity deep venous thrombosis (also consider imaging of upper extremities if swelling is present or venous catheters are in place), cessation of heparin products, and initiation of alternative anticoagulation. Patients with moderate-to-high pretest probability without HIT antibodies or intermediate pretest probability with only weakly positive HIT antibodies (based on optical density, discussed below) can resume heparin, as HIT is unlikely in these scenarios. Patients with high pretest probability with weakly positive antibodies or moderate-to-high pretest probability with moderate to strongly positive antibodies likely have HIT and should be treated as such.

LABORATORY TESTS

These can be broadly divided into two categories: Immunoassays (high sensitivity) and functional assays (high specificity).

In the appropriate clinical setting, testing for HIT antibodies with an ELISA can be useful. This test is very sensitive, but not specific. The majority of patients with positive testing for HIT antibodies will not develop clinical HIT. Thus, HIT antibody testing is more effective for ruling out rather than confirming the diagnosis of HIT.

HIT antibody optical density (OD) can be used as a correlate for HIT antibody concentration. OD range is defined as weakly positive (0.4 to 1.0), moderately positive (1.0 to 2.0), or strongly positive (>2.0). A weakly positive OD (0.4 to 1.0) is only rarely associated with functional assay positivity (1% to 5%), whereas an OD >2.0 almost always shows functional assay positivity (89% to 100%). A higher OD is also associated with a higher pretest probability score and increased risk of thrombosis. Of note, the HIT antibody IgG subtype is the pathologic antibody for HIT, and thus the use of IgG-specific ELISA kits increases the test specificity over the polyspecific (IgA/M/G) antibody. In general, patients with low pretest probability via the 4T clinical prediction score should not have HIT antibody testing performed because it has a more than 99% negative predictive value, while all patients with intermediate and high pretest probability of HIT benefit from HIT antibody testing.

The gold standard test for HIT is to measure heparin-dependent platelet activation via the functional serotonin release assay (14C-SRA). This is both a highly sensitive and specific test. Donor platelets are radiolabeled with serotonin and then incubated with patient serum and heparin. If antibodies to the platelet factor 4-heparin complex are present in the patient's serum, the platelets react and release the radiolabeled serotonin, which is then measured. Availability and turnaround time of this test is dependent on the institution, which can influence the test's clinical utility. Cases where there is intermediate pretest probability with only a weakly positive HIT antibody OD most benefit from confirmatory SRA testing.

Overall, the diagnosis of HIT can be considered confirmed by (1) a positive ELISA with OD >2.00 or (2) a positive functional assay.

IMAGING STUDIES

Doppler ultrasonography of the extremities in the correct clinical setting.

TREATMENT

- For patients with a moderate or high pretest probability, discontinue all heparin

TABLE 1 Risk Factors for Heparin-Induced Thrombocytopenia

Heparin Type	Unfractionated > Low-Molecular-Weight Heparin > Fondaparinux
Patient type	Postoperative (major > minor surgery) > medical > obstetric/pediatric
Dose[a]	Prophylactic dose > therapeutic dose > flushes
Duration	11-14 days[b] > 5-10 days > 4 days or fewer
Sex	Female > male

[a]Importance of heparin dose is uncertain because of compounding effect of patient type (e.g., postoperative patients tend to receive prophylactic-dose heparin whereas medical patients [e.g., with venous thromboembolism] are more likely to receive therapeutic-dose heparin); nevertheless, reported frequencies of heparin-induced thrombocytopenia (HIT) are relatively high in patients given postoperative prophylactic-dose heparin.
[b]Heparin exposure beyond 14 days does not usually increase the risk of HIT beyond that of an 11- to 14-day exposure.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 2 The 4Ts Score for Estimating the Pretest Probability of Heparin-Induced Thrombocytopenia

	POINTS (0, 1, or 2 for each of the four parameters; maximum points = 8)		
	2	**1**	**0**
Thrombocytopenia (acute)	>50% platelet count fall to nadir ≥20 × 10^9/L	30%-50% platelet count fall; or nadir 10-19 × 10^9/L	<30% platelet count fall; or nadir ≤10 × 10^9/L
Timing of fall in platelet count or other sequelae	Onset day 5-10 or <1 day (if heparin exposure within 30 days)	>Day 10, timing unclear, or <day 1 with recent heparin 31-100 days	Platelet count fall <day 4 (without recent heparin exposure)
Thrombosis or other sequelae	New thrombosis; skin necrosis; post-heparin bolus acute systemic reaction	Progressive or recurrent thrombosis; erythematous skin lesions; suspected thrombosis—not confirmed	None
Other cause for thrombocytopenia	No other cause for platelet count fall is evident	Possible other cause is evident	Definite other cause is present
Pretest probability score: 6-8 = High; 4-5 = Intermediate; 0-3 = Low			

From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

TABLE 3 Laboratory Assays for Heparin-Induced Thrombocytopenia

Assay	Sensitivity (%)	Specificity (%)	Positive Predictive Value (%)	Negative Predictive Value (%)
Functional assay (e.g., serotonin release assay)	88	~100	~100	81
PF4/heparin enzyme immunoassay (ELISA)	95-98	86	93	95

ELISA, Enzyme-linked immunosorbent assay; *PF4,* platelet factor 4.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

TABLE 4 Treatment Schedules for Bivalirudin and Argatroban

Anticoagulant	Dosing Protocol for HIT-Associated Thrombosis	Anticoagulant Monitoring[a]	Clearance	Half-Life (min)	Comment
Bivalirudin	No bolus; initial infusion rate: 0.15-0.20 mg/kg per hour	1.5-2.5 × baseline aPTT	Enzymic (80%); renal (20%)	25	Off-label treatment for HIT (although approved for PCI in patient with HIT); minor prolongation of INR (compared with argatroban)
Argatroban	No bolus; initial infusion rate: 2 μg/kg per minute	1.5-3.0 × baseline aPTT	Hepatobiliary	40-50	Initial dose 0.5 μg/kg per minute in hepatic insufficiency[b]; moderate or marked prolongation of INR, which complicates overlap with warfarin anticoagulation

Dosing protocols shown are appropriate for most patients with strongly suspected or confirmed HIT whether or not complicated by thrombosis. (Dosing for bivalirudin and argatroban is substantially different when given for PCI.) *aPTT,* Activated partial thromboplastin time; *HIT,* heparin-induced thrombocytopenia; *INR,* international normalized ratio; *PCI,* percutaneous coronary intervention.
[a]In general, the patient's baseline aPTT should be used for calculating target range when appropriate; otherwise the mean laboratory normal range can be used.
[b]Reduced initial dosing (e.g., 0.5-1.2 μg/kg per minute) is also appropriate in patients in intensive care units, with cardiac failure, or postcardiac surgery).
Modified from Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

exposure. Even if the patient does not have a clinically evident thrombosis, there is a significant risk of developing an incident clot within the subsequent 30 days. Thus, the patient must be started on an alternative anticoagulant.

- Two agents, both direct thrombin inhibitors, are approved for this indication (Table 4):
  1. Argatroban (preferred agent in renal failure and in hemodialysis patients; avoid in liver dysfunction).
  2. Bivalirudin (approved only for patients with HIT or at risk of HIT who are undergoing PCI; dose adjustment is required in renal failure).
- NOTE: Lepirudin is no longer available. Outside of the U.S., the factor Xa inhibitor danaparoid may be used.
- Platelet transfusion in the absence of life-threatening hemorrhage or extreme thrombocytopenia should be avoided. Risk of bleeding is low, and platelet transfusions in HIT can increase risk of arterial thrombosis.
- A direct thrombin inhibitor should be continued as a single agent until the platelet count returns to baseline (generally 150 × 109/L, but consider the individual patient's baseline).
- Warfarin can be added after platelet recovery (maximum dose of 5 mg/day to reduce risk of warfarin-induced skin necrosis and venous limb gangrene). This overlap therapy should continue until the platelet count has reached a stable plateau, the INR has reached goal (typically 2 to 3, though guidelines may vary with argatroban as it artificially elevates the INR), and after a minimum overlap of 5 days with both the direct thrombin inhibitor and warfarin.
- The length of treatment is controversial, but most clinicians agree that at least 1 mo of alternative anticoagulation is required in the absence of thrombosis, while at least 3 to 6 mo of treatment are required in the presence of thrombosis.

TABLE 5 Treatment Schedules for Danaparoid and Fondaparinux

Anticoagulant	Therapeutic Dosing Protocol for HIT-Associated Thrombosis[a]	Anticoagulant Monitoring	Clearance	Half-Life (h)	Comment
Danaparoid	Initial bolus, 2250 units[b] IV; accelerated infusion (400 units/h × 4 h, 300 units/h × 4 h; then 200 units/h IV, subsequently adjusted by antifactor Xa levels)	Antifactor Xa levels (target, 0.5-0.8 units/ml)	Renal (minor)	25	Widely approved for HIT treatment (although not in the U.S.); not available in the U.S.; low risk for in vivo cross-reactivity; prophylactic-dose therapy[c] may be appropriate when clinical suspicion for HIT is low.
Fondaparinux	7.5 mg[d] subcutaneous once daily	Anti–Xa factor levels (target levels not well established)	Renal (major)	17	Not approved for HIT treatment (although increasingly used as off-label therapy). Prophylactic-dose therapy[e] may be appropriate when clinical suspicion for HIT is low, or if there is renal insufficiency.

HIT, Heparin-induced thrombocytopenia; *IV,* intravenous.
[a]Therapeutic dosing is usually appropriate for strongly suspected or confirmed HIT (including "isolated" HIT, i.e., HIT without apparent thrombosis), or when thrombosis is documented.
[b]Adjust IV danaparoid bolus for body weight: <60 kg, 1500 units; 60-75 kg, 2250 units; 75-90 kg, 3000 units; >90 kg, 3750 units.
[c]Prophylactic-dose regimen, 750 units subcutaneous every 8 h (for renal failure, reduce to 750 units every 12 h).
[d]Five milligrams for body weight <50 kg and 10 mg for body weight >100 kg; the author sometimes gives 10 mg as the first and/or second dose (rather than 7.5 mg) for severe HIT. Because HIT treatment is usually started in the afternoon, the author usually gives the second dose (and subsequent doses) at 8 a.m. (i.e., the interval between first and second doses is often only 14-20 h rather than 24 h), which helps to achieve steady-state therapy more quickly. Dose reduction and antifactor Xa monitoring (if available) is appropriate if being used in a patient with renal insufficiency.
[e]Prophylactic-dose regimen, 2.5 mg subcutaneous every day (assumes normal renal function).
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.-

- Fondaparinux, a synthetic pentasaccharide that inhibits factor X but not thrombin, is being increasingly used for treatment of HIT despite not yet being FDA approved (Table 5). Emerging data suggest it has similar efficacy as direct thrombin inhibitors, with the additional advantages of lower bleeding risk, easier administration (subcutaneous), and lower cost. Rare cases of fondaparinux-induced HIT have been reported, however.
- The use of direct oral anticoagulants (e.g., rivaroxaban, dabigatran, apixaban) is being studied. Retrospective reviews have shown DOACs to be safe and effective for the treatment of HIT, though randomized prospective data remain lacking.
- In patients with confirmed HIT, all heparin products should be avoided for life. A possible exception is in patients who require brief intraoperative anticoagulation such as cardiac bypass surgery.

REFERRAL

Request a hematology consultation.

PEARLS & CONSIDERATIONS

COMMENTS

- HIT paradoxically causes thrombocytopenia and *clotting,* not bleeding.
- It is unclear whether patients with HIT should be considered heparin allergic lifelong. Risk of recurrent HIT with heparin rechallenge years later is relatively low, about 5% in one small study (though recurrence risk is higher perioperatively). If such a patient requires surgery with heparin (e.g., on-pump cardiac bypass), consider perioperative argatroban.
- Consult the coagulation laboratory and/or hematology when bridging patients on argatroban to warfarin, as argatroban concomitantly raises the INR in most assays. Some clinicians will use a higher target than 2 to 3 during the bridging period for this reason.
- Be alert to heparin exposure in the absence of anticoagulation or DVT prophylaxis: Hospitalized patients are often exposed to heparin lock flushes, heparin-coated catheters, or heparin-coated guidewires—any of which could precipitate HIT.

PREVENTION

Strongly consider the use of low-molecular-weight heparin in place of unfractionated heparin in hospitalized patients with a stable creatinine clearance of 30 ml/min or greater. Such a preventive strategy can reduce the risk of HIT by over 90% and yield cost savings in testing and treatment.

BASIC INFORMATION

DEFINITION

Hepatic encephalopathy is a neuropsychiatric syndrome occurring in patients with severe impairment of liver function and consequent accumulation of toxic products not metabolized by the liver. It is characterized by gradual impairment of the ability to perform mental tasks and to react to external stimuli. Fig. 1 illustrates the hepatic encephalopathy grades in acute liver failure. ***Minimal hepatic encephalopathy*** refers to patients with hepatic cirrhosis and mild cognitive impairment, but no history of overt encephalopathy.

SYNONYMS

Hepatic coma
Portal systemic encephalopathy
HE

ICD-10CM CODES

G92	Toxic encephalopathy
G93.40	Encephalopathy, unspecified
G93.41	Metabolic encephalopathy
K70.40	Alcoholic hepatic failure without coma
K70.41	Alcoholic hepatic failure with coma
K72.0	Acute and subacute hepatic failure
K72.00	Acute and subacute hepatic failure without coma
K72.01	Acute and subacute hepatic failure with coma
K72.1	Chronic hepatic failure
K72.10	Chronic hepatic failure without coma
K72.11	Chronic hepatic failure with coma
K72.9	Hepatic failure, unspecified
K72.90	Hepatic failure, unspecified without coma
K72.91	Hepatic failure, unspecified with coma
K91.82	Postprocedural hepatic failure

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE/PREVALENCE: Hepatic encephalopathy occurs in >40% of all cases of cirrhosis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Hepatic encephalopathy can be classified by clinical stages described in Table 1. Other widely used scales are the four score criteria and the West Haven criteria. The West Haven criteria for grading hepatic encephalopathy is as follows:

- Grade (0): No abnormalities noted
- Grade (1): Unawareness (mild), euphoria or anxiety, shortened attention span, impairment of calculation ability, lethargy, or apathy
- Grade (2): Disorientation to time, obvious personal change, inappropriate behavior
- Grade (3): Somnolence to stupor, responsiveness to stimuli, gross disorientation, bizarre behavior
- Grade (4): Coma

The physical examination in hepatic encephalopathy varies with the stage and may reveal the following abnormalities:

- Skin: Jaundice, palmar erythema, spider angiomata, ecchymosis, dilated superficial periumbilical veins (caput medusae) in patients with cirrhosis
- Eyes: Scleral icterus, Kayser-Fleischer rings (Wilson disease)
- Breath: Fetor hepaticus
- Chest: Gynecomastia in men with chronic liver disease
- Abdomen: Ascites, small nodular liver (cirrhosis), tender hepatomegaly (congestive hepatomegaly)
- Rectal examination: Hemorrhoids (portal hypertension), guaiac-positive stool (alcoholic gastritis, bleeding esophageal varices, peptic ulcer disease, bleeding hemorrhoids)
- Genitalia: Testicular atrophy in males with chronic liver disease
- Extremities: Pedal edema from hypoalbuminemia
- Neurologic: Flapping tremor (asterixis), obtundation, coma with or without decerebrate posturing

ETIOLOGY

- Hepatic encephalopathy is thought to be caused mainly by accumulation of unmetabolized ammonia. The shunting of ammonia into the systemic circulation results in neuronal dysfunction leading to hepatic encephalopathy
- Precipitating factors in patients with underlying cirrhosis (upper gastrointestinal bleeding, hypokalemia, hypomagnesemia, analgesic and sedative drugs, sepsis, alkalosis, increased dietary protein)
- Acute fulminant viral hepatitis
- Drugs and toxins (e.g., isoniazid, acetaminophen, diclofenac and other NSAIDs, statins, methyldopa, loratadine, propylthiouracil, lisinopril, labetalol, halothane, carbon tetrachloride, erythromycin, nitrofurantoin, troglitazone, herbal products, flavocoxid)
- Reye syndrome
- Shock and/or sepsis
- Fatty liver of pregnancy
- Metastatic carcinoma, hepatocellular carcinoma
- Other: Autoimmune hepatitis, ischemic venoocclusive disease, sclerosing cholangitis, heat stroke, amebic abscesses

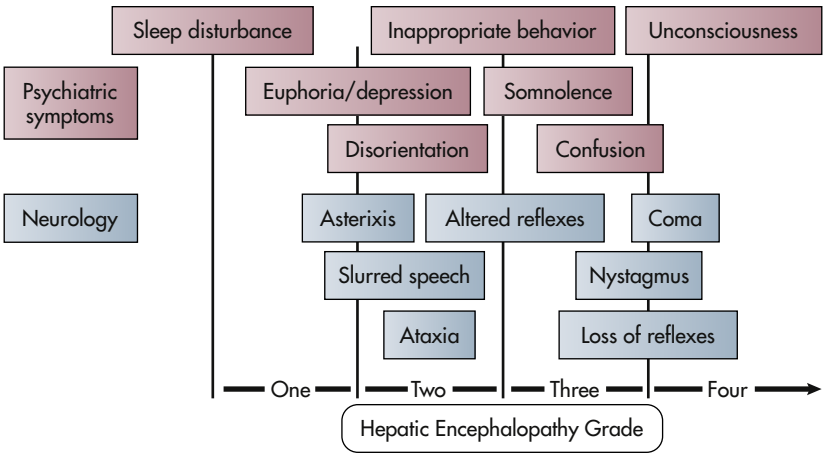

FIG. 1 Hepatic encephalopathy grade in acute liver failure. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 4, Philadelphia, 2014, Elsevier.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Delirium caused by medications or illicit drugs
- Cerebrovascular accident, subdural hematoma
- Meningitis, encephalitis
- Hypoglycemia
- Uremia
- Cerebral anoxia
- Hypercalcemia
- Metastatic neoplasm to brain
- Alcohol withdrawal syndrome/Wernicke-Korsakoff syndrome
- Hyponatremia
- Postictal state

WORKUP

Hepatic encephalopathy should be considered in any patient with cirrhosis who presents with neuropsychiatric manifestations. Exclude other etiologies with comprehensive history (obtained from patient, relatives, and others), physical examination, and laboratory and imaging studies. A pertinent history should include exposure to hepatitis, ethanol intake, drug history, exposure to toxins, IV drug abuse, measles or influenza with aspirin use (Reye syndrome), and history of carcinoma (primary or metastatic). Minimal hepatic encephalopathy may not be obvious on clinical examination, but can be detected with neurophysiologic and neuropsychiatric testing.

LABORATORY TESTS

- Alanine aminotransferase, aspartate aminotransferase, bilirubin, alkaline phosphatase, glucose, calcium, electrolytes, blood urea nitrogen, creatinine, albumin
- Complete blood count, platelet count, prothrombin time, partial thromboplastin time
- Serum and urine toxicology screen in suspected medication or illegal drug use

TABLE 1 Clinical Stages of Hepatic Encephalopathy

Stage	Asterixis	EEG Changes	Clinical Manifestations
I (prodrome)	Slight	Minimal	Mild intellectual impairment, disturbed sleep-wake cycle
II (impending)	Easily elicited	Usually generalized	Drowsiness, confusion, coma/inappropriate behavior, disorientation, mood swings
III (stupor)	Present if patient cooperative	Grossly abnormal slowing of rhythm	Drowsy, unresponsive to verbal commands, markedly confused, delirious, hyperreflexia, positive Babinski sign
IV (coma)	Usually absent	Appearance of delta waves, decreased amplitudes	Unconscious, decerebrate or decorticate response to pain present (stage IVA) or absent (stage IVB)

EEG, Electroencephalogram.
From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, WB Saunders.

- Blood and urine cultures, urinalysis
- Venous ammonia level. Measurement of serum ammonia level is useful in the evaluation of acute liver failure because levels correlate with the severity of encephalopathy and elevated levels are predictive of severe encephalopathy and cerebral edema. It is not useful for the evaluation or screening of hepatic encephalopathy in patients with chronic liver disease because it can neither rule in nor rule out hepatic encephalopathy, and levels do not correlate with the degree of encephalopathy
- Arterial blood gases

IMAGING STUDIES

CT scan or MRI of the brain may be useful in selected patients to exclude other etiologies when diagnosis is unclear.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Identification and treatment of precipitating factors.
- Restriction of protein intake is ill-advised and not necessary, since normal protein intake does not appear to exacerbate hepatic encephalopathy.

ACUTE GENERAL Rx

The approach to patients with high grade hepatic encephalopathy is shown in Fig. 2. Table 2 summarizes the management of fulminant hepatic failure.

Reduction of colonic ammonia production:

- Lactulose 25 ml twice daily initially; dose is subsequently adjusted depending on clinical response to achieve production of 3 bowel movements daily. IV ornithine aspartate should be considered for those not responding to lactulose.
- The oral antibiotic rifaximin (550 mg PO bid) is effective in reducing the risk of recurrent hepatic encephalopathy in patients with cirrhosis. It can be taken with lactulose, and the combination of lactulose and rifaximin is superior to lactulose alone in reversing hepatic encephalopathy. Rifaximin has also been shown to be effective in improving psychometric performance and health-related quality of life in patients with minimal hepatic encephalopathy. It is well tolerated but expensive.
- Probiotics (e.g., 1 capsule containing 112.5 billion viable lyophilized bacteria tid) might also be beneficial in altering gut flora to reduce ammonia production.

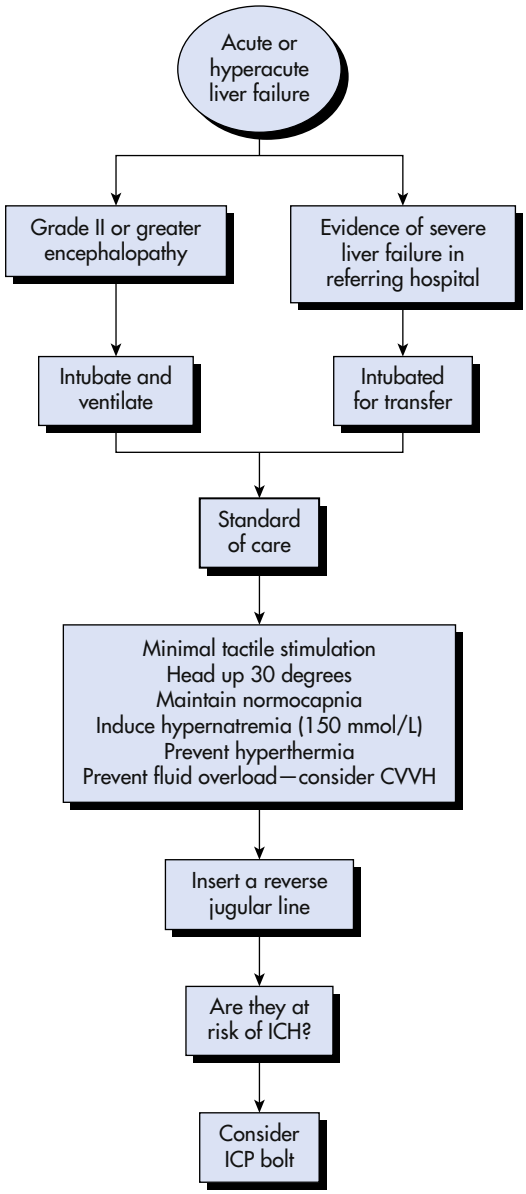

FIG. 2 Initial management of patient with high-grade encephalopathy. CVVH, Continuous venovenous hemofiltration; ICH, intracranial hypertension; ICP, intracranial pressure. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.)

Treatment of cerebral edema:

- Cerebral edema is often present in patients with acute liver failure, and it accounts for nearly 50% of deaths. Monitoring intracranial pressure by epidural, intraparenchymal, or subdural transducers and treatment of cerebral edema with mannitol (100 to 200 ml of 20% solution [0.3 to 0.4 g/kg of body weight]) given by rapid IV infusion are helpful

TABLE 2 Management of Fulminant Hepatic Failure

No sedation except for procedures
Minimal handling
Enteric precautions until infection ruled out
Monitor:
1. Heart and respiratory rate
2. Arterial BP, CVP
3. Core/toe temperature
4. Neurologic observations
5. Gastric pH (>5.0)
6. Blood glucose (>4 mmol/L)
7. Acid-base
8. Electrolytes
9. PT, PTT

Fluid balance:
1. 75% maintenance
2. Dextrose 10%-50% (provide 6-10 mg/kg/min)
3. Sodium (0.5-1 mmol/L)
4. Potassium (2-4 mmol/L)

Maintain circulating volume with colloid/FFP coagulation support only if required

Drugs:
1. Vitamin K
2. H2 antagonist
3. Antacids
4. Lactulose
5. N-acetylcysteine for acetaminophen toxicity
6. Broad-spectrum antibiotics
7. Antifungals

Nutrition:
1. Enteral feeding (1-2 g protein/kg/day)
2. PN if ventilated

BP, Blood pressure; *CVP,* central venous pressure; *FFP,* fresh frozen plasma; *PN,* parenteral nutrition; *PT,* prothrombin time; *PTT,* partial thromboplastin time.
From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, WB Saunders.

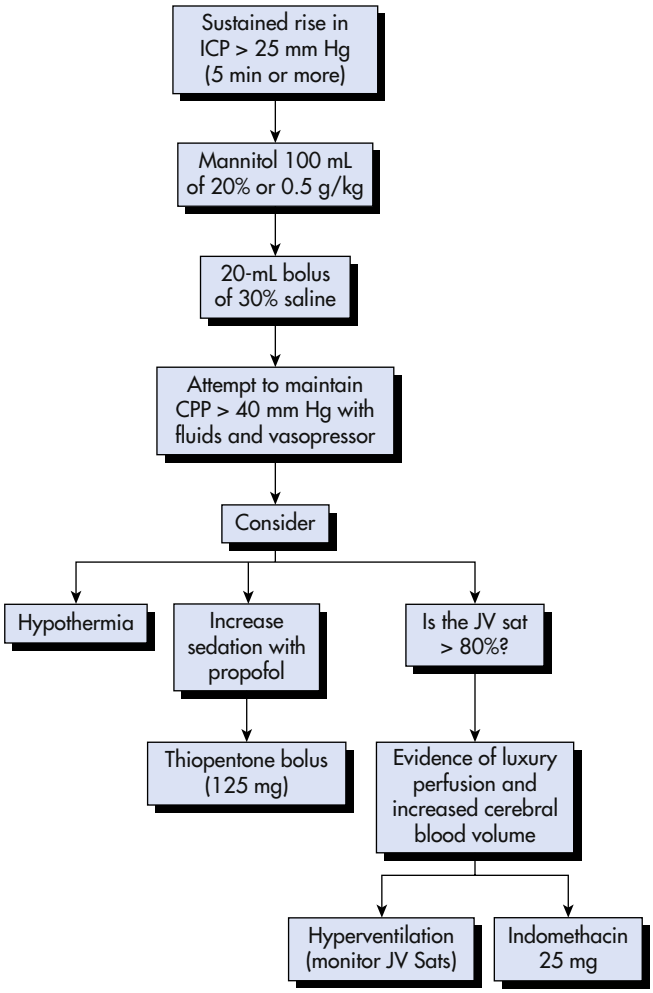

FIG. 3 Management of a sustained rise in intracranial pressure. *CPP,* Cerebral perfusion pressure; *ICP,* intracranial pressure; *JV,* jugular venous; *Sats,* saturation. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.)

in selected patients (e.g., potential transplantation patients).
- Fig. 3 illustrates the management of a sustained rise in intracranial pressure in liver failure.
- Dexamethasone and hyperventilation (useful in head injury) are of little value in treating cerebral edema from liver failure.

CHRONIC Rx

- Avoidance of any precipitating factors (e.g., high-protein diet, medications).
- Consideration of liver transplantation in selected patients with progressive or recurrent encephalopathy (Box E1). Liver transplantation remains the only curative therapeutic option.

DISPOSITION

Prognosis varies with the underlying etiology of the liver failure and the grade of encephalopathy (generally good for grades 1 or 2; poor for grades 3 or 4). Without proper therapy, the survival rate at 1 yr is 42% and decreases to 23% at 3 yr.

REFERRAL

The early stages of hepatic encephalopathy can be managed in the outpatient setting, whereas stages III or IV require hospital admission.

PEARLS & CONSIDERATIONS

COMMENTS

- Trials have shown that adding IV albumin to lactulose may improve outcomes in severe hepatic encephalopathy by reducing oxidative stress through reduction of levels of circulating cytokines and endotoxins.
- Long-acting benzodiazepines should not be used to treat anxiety and sleep disorders in patients with cirrhosis, as they may precipitate encephalopathy.
- Patients not responding to supportive therapy should be evaluated for liver transplantation.
- Not all patients with cirrhosis develop hepatic encephalopathy. It has been shown that 40% of persons with cirrhosis and minimal hepatic encephalopathy do not develop overt hepatic encephalopathy in long-term follow-up. There are genetic factors associated with development of hepatic encephalopathy in patients with cirrhosis. Genetic analyses have shown that glutaminase TACC and CACC haplotypes are linked to the risk for overt hepatic encephalopathy.

BOX E1 Various Prognostic Criteria Used for Liver Transplantation in Patients with Fulminant Hepatic Failure

King's College Criteria

Acetaminophen overdose:

- Arterial pH <7.3 (irrespective of grade of encephalopathy) or
- PT >100 sec (INR >6.5)
- Serum creatinine >3.4 mg/dl (>300 μmol/L)
- Patients with grade III and IV hepatic encephalopathy

Nonacetaminophen liver injury:

- PT >100 sec (INR >6.5) (irrespective of grade of encephalopathy) or any three of the following variables:
  1. Age <10 or >40 yr
  2. Non-A, non-B hepatitis, halothane hepatitis, idiosyncratic drug reactions
  3. Jaundice >7 days before onset of encephalopathy
  4. Serum bilirubin 17.4 mg/dl (300 μmol/L)
  5. PT >50 sec

Cliché Criteria

Factor V <20% in persons <30 yr or both of the following:

- Factor V <30% in patients >30 yr
- Grade III or IV encephalopathy

Serum Gc Globulin Levels

Decreasing Gc levels due to dying hepatocytes

Serum α-Fetoprotein Level

Serial increase from day 1 to day 3 has shown correlation with survival

Liver Biopsy

70% necrosis is discriminant of 90% mortality

Gc, Plasma group-specific component protein; *INR,* international normalized ratio; *PT,* prothrombin time.
From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.

Hepatitis A PTG

BASIC INFORMATION

DEFINITION

Hepatitis A is generally an acute self-limiting infection of the liver by an enterically transmitted picornavirus, hepatitis A virus (HAV). Infection may range from asymptomatic to fulminant hepatitis.

SYNONYMS

Infectious hepatitis
Short incubation hepatitis
Type A hepatitis
HAV (hepatitis A virus)

ICD-10CM CODES

B15.9 Hepatitis A without hepatic coma
B15.0 Hepatitis A with hepatic coma

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Hepatitis A occurs worldwide, affecting 1.4 million people annually and accounting for 20% to 40% of cases of viral hepatitis in the U.S. It is the most common cause of viral hepatitis worldwide
- The seroprevalence increases with age, ranging from 10% in individuals aged <5 yr to 74% in those aged >50 yr
- In the U.S., average disease rate was ~15 cases/100,000 persons/yr before routine vaccination of all children in certain states. The incidence after 2005 is about 1 case/100,000
- The incidence is relatively higher in some regions in the U.S., including Arizona, Alaska, California, Idaho, Nevada, New Mexico, Oklahoma, Oregon, South Dakota, and Washington
- At-risk groups include:
  1. Residents and staff of group homes
  2. Children and employees of day care centers
  3. People who engage in oral-anal contact, regardless of sexual orientation
  4. IV drug abusers
  5. Travel to endemic areas
  6. Areas of overcrowding, poor sanitation, inadequate sewage treatment

PREVALENCE:

- Approximately three fourths of the U.S. population has serologic evidence of prior infection.
- Anti-HAV prevalence has an inverse relation to income and household size.

PREDOMINANT SEX: None, except higher infection rates seen in men who have sex with men who engage in oral–anal contact.

PREDOMINANT AGE/PEAK INCIDENCE:

- In areas of high rates of hepatitis A, virtually all children are infected while younger than 10 yr, but disease is rare.
- In areas of moderate rates of hepatitis A, disease occurs in late childhood and young adults.
- In areas of low rates of hepatitis A, most cases occur in young adults.

INCUBATION PERIOD: Averages 30 days (15 to 50)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Infection with HAV may have acute or subacute presentation, icteric or anicteric. Severity of illness seems to increase with age (90% of infection in children aged <5 yr may be subclinical).
- The incubation period of HAV is 2 to 6 wk.
- A preicteric, prodromal phase of approximately 1 to 14 days; 15% no apparent prodrome. Symptoms are usually abrupt in onset and may include anorexia, fatigue, malaise, nausea, vomiting, fever, headache, and mild abdominal pain.
- Less common symptoms are chills, myalgias, arthralgias, upper respiratory symptoms, constipation, diarrhea, pruritus, urticaria.
- Jaundice occurs in >70% of patients. Patients older than 30 yr are more likely than younger individuals to have jaundice.
- The icteric phase is preceded by dark urine.
- Bilirubinuria is typically followed a few days later by clay-colored stools and icterus.

PHYSICAL EXAMINATION

- Jaundice: Peaks in severity 2 wk after onset
- Hepatomegaly
- Splenomegaly
- Cervical lymphadenopathy
- Evanescent rash
- Petechiae
- Cardiac arrhythmias

COMPLICATIONS

- Cholestasis
- Fulminant hepatitis
- Arthritis
- Myocarditis
- Optic neuritis
- Transverse myelitis
- Thrombocytopenic purpura
- Aplastic anemia
- Red cell aplasia
- Henoch-Schönlein purpura
- IgA dominant glomerulonephritis

ETIOLOGY

- Caused by HAV, a 27-nm, nonenveloped, icosahedral, positive-stranded RNA virus.
- Transmission is fecal-oral route, from person to person. Transmission occurs with close contact or with food- or water-borne outbreaks with inadequately purified water or cooked foods. Recent outbreaks have involved green onions and tomatoes.
- Parenteral transmission is considered rare.
- Vertical transmission has also been reported.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other hepatitis virus (B, C, D, E): Table 1 summarizes serology and PCR test results
- Infectious mononucleosis
- Cytomegalovirus infection
- Herpes simplex virus infection
- Leptospirosis
- Brucellosis
- Drug-induced liver disease
- Ischemic hepatitis
- Autoimmune hepatitis

WORKUP

- IgM antibody specific for HAV
- Liver function tests; ALT and AST elevations are sensitive for liver damage but not specific for HAV
- Elevated ESR
- CBC; may find mild lymphocytosis

TABLE 1 Diagnostic Blood Tests: Serology and Viral Polymerase Chain Reaction

HAV	HBV	HCV	HDV	HEV
Acute/Active Infection				
Anti-HAV IgM (+)	Anti-HBc IgM (+)	Anti-HCV (+)	Anti-HDV IgM (+)	Anti-HEV IgM (+)
Blood PCR positive*	HBsAg (+) Anti-HBs (–) HBV DNA (+) (PCR)	HCV RNA (+) (PCR)	Blood PCR positive HBsAg (+) Anti-HBs (–)	Blood PCR positive*
Past Infection (Recovered)

TABLE 2 Recommendations for Routine Preexposure Use of Hepatitis A Virus Vaccine

Group	Comments
Children	Vaccine should be given to all children at age 1 yr (12-23 mo).* Vaccination of children 2-18 yr may also be warranted.†
International travelers‡	IG may be given in addition to or instead of vaccine; children <12 mo should receive IG.
Close contacts of newly arriving international adoptees	All persons who anticipate close personal contact (e.g., household contact or regular babysitter) during the first 60 days after arrival
Men who have sex with men	Includes adolescents
Illicit drug users	Includes adolescents
Persons with chronic liver disease, such as those with hepatitis B or C	Increased risk of fulminant hepatitis A with HAV infection
Persons receiving clotting factor concentrates	
Persons who work with HAV in research laboratory settings	

*Hepatitis A vaccine is not licensed for children <12 mo.
†States and communities with existing vaccination programs for children aged 2 to 18 yr are encouraged to maintain these programs. Catch-up vaccination for this age group may be warranted elsewhere in the context of ongoing outbreaks among children.
‡Persons traveling to Canada, Western Europe, Japan, Australia, or New Zealand are at no greater risk than in the U.S.
HAV, Hepatitis A virus; *IG,* immunoglobulin.
From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases*, ed 8, Philadelphia, 2015, Saunders.

LABORATORY TESTS

- Diagnosis confirmed by IgM anti-HAV; it is detectable in almost all infected patients at presentation and remains positive for 3 to 6 mo.
- A fourfold rise in titer of total antibody (IgM and IgG) to HAV confirms acute infection.
- HAV detection in stool and body fluids by electron microscopy.
- HAV RNA detection in stool, body fluids, serum, and liver tissue.
- ALT and AST usually more than 8 times normal in acute infection.
- Bilirubin usually 5 to 15 times normal.
- Alkaline phosphatase minimally elevated, but higher level in cholestasis.
- Albumin and prothrombin time are generally normal; if elevated, they may herald hepatic necrosis.
- Fig. 1 illustrates the typical course of hepatis A.

IMAGING STUDIES

- Rarely useful
- Sonogram (fulminant hepatitis)

Rx TREATMENT

- Usually self-limited
- Supportive care
- Those with fulminant hepatitis may require hospitalization and treatment of associated complications
- Activity as tolerated
- Advise to avoid alcohol and hepatotoxic drugs
- Patients with fulminant hepatitis should be assessed for liver transplantation

CHRONIC Rx

No chronic HAV and no chronic carrier state. The majority of patients have resolution of symptoms and liver abnormalities within 3 mo.

DISPOSITION

- Follow-up as outpatient.
- Most patients recover within 3 mo of infection, although 5% to 10% of patients will experience a relapse in the first 6 mo.
- HAV is a self-limited infection and does not cause chronic hepatitis.

REFERRAL

- To a hepatologist if severe, fulminant hepatitis develops
- To a transplant surgeon if liver transplant becomes a consideration for fulminant hepatitis and liver failure

PEARLS & CONSIDERATIONS

- All cases of hepatitis A should be reported to the public health authorities because foodborne or water-borne outbreaks may occur, and public health efforts (mass vaccination or immunoglobulin therapy) may prevent secondary cases.
- Hepatitis A is a common illness in internationally traveled and developing countries. Pretravel vaccination is strongly recommended for travelers who are HAV susceptible. Table 2 summarizes recommendations for preexposure use of hepatitis A virus vaccine. Updated dosage recommendations are described in Table 3.
- Handwashing is important because the hepatitis A virus may survive for up to 4 hours on the fingertips.
- There have been significant recent outbreaks of hepatitis A in the U.S. In 2016-2018 there was an increase of cases by 294% vs. cases in 2013-2015. This was mostly among the homeless, IV drug abusers, men having sex with men, and individuals who consumed certain imported food items.

PREVENTION

- Improvement in hygiene and sanitation
- Heating food
- Avoidance of water and foods from endemic area

PASSIVE IMMUNIZATION

- Immunoglobulin provides protection against HAV through passive transfer of antibody.
- Preexposure prophylaxis indicated for people traveling to endemic areas with immune globulin (Ig 0.02 or 0.06 ml/kg given IM) who have not received or cannot receive the hepatitis A vaccine before departure. The lower dose is effective for up to 3 mo, and the higher dose is effective for up to 5 mo.
- Postexposure prophylaxis (PEP): For individuals with a recent exposure to hepatitis A who have not received the vaccine, post-exposure prophylaxis is warranted with either immunoglobulin (Ig 0.02 ml/kg given IM) or a single dose of the hepatitis A vaccine within 2 wk of the exposure. For healthy persons ages 12 mo to 40 yr of age, a single dose of the hepatitis

TABLE 3 Indications and Updated Dosage Recommendations for GamaSTAN S/D Human Immune Globulin for Preexposure and Postexposure Prophylaxis against Hepatitis A Infection

Indication	Updated Dosage Recommendation
Preexposure prophylaxis	
Up to 1 mo of travel	0.1 ml/kg
Up to 2 mo of travel	0.2 ml/kg
2 mo of travel or longer	0.2 ml/kg (repeat every 2 mo)
Postexposure prophylaxis	0.1 ml/kg

From Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

A vaccine should be given. Children <12 mo, adults >40 yr of age, and persons who have chronic liver disease and who are immunocompromised should receive immunoglobulin.

ACTIVE IMMUNIZATION

- There are several inactivated and attenuated hepatitis vaccines; only the inactivated vaccines are currently available for use and they have been found to be safe and highly immunogenic: HAVRIX or VAQTA. These can be used in adults and children older than 12 mo. They are given as a two-dose regimen 6 mo to 1 yr apart. A combined hepatitis A and hepatitis B vaccine called TWINRX is also available.
- Protective antibody levels were reached in 94% to 100% of adults 1 mo after the first dose; similar results have been found for children and adolescents.
- Theoretic analyses of antibody levels estimate duration of immunity to be 10 to 20 yr.
- Vaccine should be considered for persons who are at risk. Those traveling to or working in endemic areas, men who have sex with men, illegal drug users, persons with chronic liver disease, and children in areas with high rates of hepatitis A infection.
- The Advisory Committee on Immunization Practices recommends routine hepatitis A vaccination for all children beginning at 12 to 23 mo of age. Simultaneous administration of MMR and HCPA vaccines is recommended for infants aged 6 to 11 mo traveling internationally. The travel-related dose for infants aged 6 to 11 mo should not be counted towards the routine 2-dose series.

BASIC INFORMATION

DEFINITION

Hepatitis B is an acute infection of the liver parenchymal cells caused by the hepatitis B virus (HBV).

SYNONYMS

Serum hepatitis
Long incubation (30 to 180 days) hepatitis HBV
HBV

ICD-10CM CODES

B16	Acute hepatitis B
B16.0	Acute hepatitis B with delta-agent with hepatic coma
B16.1	Acute hepatitis B with delta-agent without hepatic coma
B16.2	Acute hepatitis B without delta-agent with hepatic coma
B16.9	Acute hepatitis B without delta agent and without hepatic coma
B18.0	Chronic viral hepatitis B with delta-agent
B18.1	Chronic viral hepatitis B without delta-agent
B19.1	Unspecified viral hepatitis B
B19.10	Unspecified viral hepatitis B without hepatic coma
B19.11	Unspecified viral hepatitis B with hepatic coma

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- The CDC estimated that in 2015 there were 21,900 cases of acute hepatitis B, with an overall incidence of 1.1 cases per 100,000.
- Much higher incidence in Europe (~1 million new cases annually) and in areas of high endemicity.
- In the U.S., transmission is mainly horizontal (percutaneous and mucous membrane exposure to infectious blood and other body fluids [e.g., sexual transmission, either homosexual or heterosexual]); also from needle sharing among drug abusers; occupational exposure to contaminated blood and blood products; persons receiving transfusions of blood and blood products; and hemodialysis patients.

NOTE: Improved screening of blood and blood products has greatly reduced, although not eliminated, the risk of posttransfusion HBV infection.

- In areas of high endemicity, transmission is largely vertical (perinatal): HBV exists in the blood and body fluids. Perinatal transmission from HBsAg-positive mothers is as high as 90% unless immunoprophylaxis is given.

PREVALENCE:

- The WHO estimates that 400 million people worldwide (6% of the population) are chronic HBV carriers. North America, Western Europe, and Australia are areas of low prevalence, <2%. In the U.S. an estimated 800,000 to 2.2 million people have chronic HBV infection. About two thirds of them are unaware that they are infected.
- Africa, Asia, and the Western Pacific region are areas of high prevalence, ≥8%.
- Southern and Eastern Europe have intermediate rates, 2% to 7%.
- Chronically infected persons, those with positive HBsAg for >6 mo, represent the major source of infection.
- As many as 95% of infants and children aged <5, who typically have subclinical acute infection, will become chronic HBV carriers.
- Adults are more likely to have clinically evident acute infection, but only 1% to 5% will develop chronic infection.
- ~0.1% of patients with acute infection will develop fulminant acute hepatitis resulting in death.

PREDOMINANT SEX:

- Predominant in males because of increased IV drug abuse, homosexuality.
- Females more commonly terminate in chronic carrier state.

PREDOMINANT AGE: 20 to 45 yr
PEAK INCIDENCE: 30 to 45 yr of age, at rates of 5% to 20%
GENETICS: Neonatal infection:

- Rare in the U.S.
- High (up to 90%) in areas of high endemicity (only 5% to 10% of perinatal infections occur in utero).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The incubation period of HBV infection is 4 to 24 wk. HBV infection presents as acute hepatitis in a minority of patients
- Patients often present with nonspecific symptoms
- Profound malaise (Fig. E1)
- Many asymptomatic cases
- Prodrome:
  1. 15% to 20% serum sickness (urticaria, rash, arthralgia) during early HBsAg
  2. HBsAg-Ab complex disease (polyarteritis nodosa–arthritis, arteritis, glomerulonephritis)
- Hepatomegaly (87%) with right upper quadrant (RUQ) tenderness:
  1. Hepatic punch tenderness
  2. Splenomegaly: Rare (10% to 15%)
- Jaundice (30% of patients), dark urine, with occasional pruritus
- Variable fever (when present, generally precedes jaundice and rapidly declines following onset of icteric phase)
- Spider angiomata: Rare; resolves during recovery
- Rare polyarteritis nodosa, cryoglobulinemia

ETIOLOGY

- Caused by HBV (42-nm hepadnavirus with an outer surface coat [HBsAg], inner nucleocapsid core [HBcAg; HBeAg]; DNA polymerase; and partially double-stranded DNA genome). There are eight genotypes (A to H) based on nucleotide sequence. The prevalence of each genotype varies widely.
- Transmission by parenteral route (needle use, tattooing, ear piercing, acupuncture, transfusion of blood and blood products, hemodialysis, sexual contact), perinatal transmission.
- Infection may result from contact of infectious material with mucous membranes and open skin breaks (e.g., HBV is stable and can be transmitted from toothbrushes, utensils, razors, baby toys, assorted medical equipment [respirators, endoscopes]).
- Oral intake of infectious material may result in infection through breaks in the oral mucosa.
- Food or water are virtually never found to be sources of HBV infection.
- Infection occurs primarily in liver, where necrosis probably results from cytotoxic T-cell response, direct cytopathic effect of HBcAg (core antigen), high-level HBsAg (surface antigen) expression, or coinfection with delta (D) hepatitis virus (RNA delta core within HBsAg envelope).
- Recovery (>90%):
  1. Fulminant hepatitis occurring in <1% (especially if coinfected with hepatitis D); 80% fatal
  2. Unusual (5%) prolonged acute disease for 4 to 12 mo, with recovery
  3. Overall fatality increases with age and viral inoculation (e.g., transfusions)
- Chronic hepatitis B (CHB) infection (1% to 2%), four phases:
  1. Immune-tolerant phase: A highly replicative/low-inflammatory phase where HBV DNA levels are high (typically >1 million IU/ml), ALT levels are normal, and biopsies have minimal signs of significant inflammation or fibrosis.
     a. This phase can persist for yrs, especially in those infected prenatally.
     b. With age there is a likely transformation to an HBeAg-positive immune-active phase.
  2. HBeAg-positive immune-active phase: Elevated ALT and HBV DNA levels in conjunction with liver injury (≥20,000 IU/ml). Median age of onset is 30 yr in those infected at a young age. Biopsy will show moderate to severe inflammation or fibrosis.
  3. Inactive CHB phase: HBV DNA levels are low or undetectable (<2000 IU/ml), ALT levels are normal, and anti-HBe is present. Biopsy shows minimal necroinflammation but variable fibrosis.
  4. HBeAg-negative immune reactivation phase: Elevated ALT and elevated HBV DNA (≥2000 IU/ml). Biopsy will show moderate to severe necroinflammation and fibrosis.
- Table 1 summarizes causes of hepatitis flares in patients with CHB.
- The most feared complications of CHB are cirrhosis and hepatocellular carcinoma (HCC), which kill more than 300,000 people/yr

TABLE 1 Causes of Hepatitis Flares in Patients with Chronic Hepatitis B

Cause of Flare	Comment
Spontaneous	Factors that precipitate viral replication are unclear
Immunosuppressive therapy	Flares are often observed during withdrawal of the agent; preemptive antiviral therapy is required
Antiviral therapy for HBV	
Interferon	Flares are often observed during the second to third mo of therapy in 30% of patients; may herald virologic response
Nucleoside analog	
During treatment	Flares are no more common than with placebo
